The Hunterian Lectures

ON

THE EVOLUTION OF THE PELVIC FLOOR IN THE NON-MAMMALIAN VERTEBRATES AND PRONOGRADE MAMMALS.

Delivered before the Royal College of Surgeons of England on March 4th and 7th, 1910,

BY R. H. PARAMORE, M.D. LOND., F.R.C.S. ENG.

LECTURE I.—NON-MAMMALIAN VERTEBRATES.

Delivered on March 4th.

INTRODUCTION.

MR. PRESIDENT, LADIES, AND GENTLEMEN,—In order to appreciate the significance of the pelvic floor musculature in man it has seemed necessary to me to investigate the several homologous anatomical conditions existing in the main types of the primary groups of the vertebrates, and to inquire into the manner in which anatomical structure has reacted to a modification of external environmental forces, in order that the internal visceral requirements of the individual, in spite of such change, might still continue to be satisfactorily met.

It may be thought that such an investigation, however interesting, is almost superfluous, and that an examination of the pelvic floor in the dissecting-room would suffice to explain how it acts in the living. Anyone who thinks so should look into the literature of the subject, and he will find that paper after paper has appeared, founded on an anatomical basis, but leading to no definite, clear, irresistibly convincing conception of the function of this musculature. According to Sappey, of all the muscles in the body the levator ani has been the most studied but is the least understood. No one would be content with the result of dissection to come to a conclusion concerning the functions of an organ, such as the liver, although such dissection will show that it receives all the blood from the intestine, and must therefore in some way be intimately related to the assimilation of food. It is only by experiment in the living that the functions of the liver have been disclosed, and it is only in a similar way that the functions of the pelvic floor can be revealed. Physiological experiment has, indeed, shown that by appropriate stimulation a living muscle fibre becomes shorter, and that by such contraction is capable of doing work, of moving limbs, &c.; but such inquiry will not demonstrate the reason of its activity in the body, although it shows the manner of it. It is only by such investigations as those instituted by Professor C. S. Sherrington with such brilliant and revolutionary results that the functions of various muscle groups concerned in the causation of various definite limb movements are becoming to be understood. It may be possible that such laboratory experiments, if arranged to demonstrate the functions of the levator ani, will solve the riddle of its existence; but such experiments can only be successful when the conditions calling the function of the muscle into play are provided, and this provision depends on considerable knowledge, which appears at present to be scarcely forthcoming. It is not, therefore, to the result of some such experiment I ask your attention, for none, as far as I know, has been performed. There is another, perhaps surer, way of studying the subject, and that is the investigation of the results obtained in that huge physiological laboratory, which is coextensive with the domain of Nature, and in which experiments have been in progress ever since life began. For Nature, by endowing the individual with the power of adaptation to new surroundings, which such individual may have been coerced to enter, as the result of some geologic disaster or climatic change, or from persecution of companions, or hunger, or from other causes, has permitted adaptive alterations in structure to occur—which we believe are necessarily correlated with the forces that caused them—so that the individual, in spite of that change, might continue to exist. That is to say, Nature has allowed a series of physiological experiments to be made, the results of which lie buried in the bodies of the present-day survival of types, more or less unaltered, of those passed individuals.

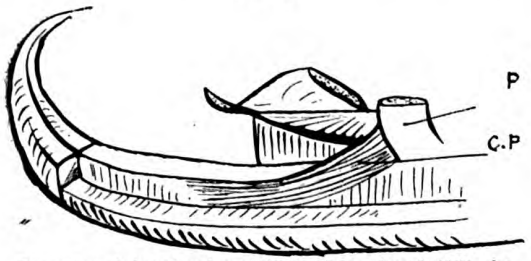
It may be supposed that such results throw but little light on the condition in man; but when we remember that the mechanism of life in all is similar, and that it depends on identical essentials, the application of such experiments must be admitted. The vertebrates are not only built on one plan, but the physiological mechanism of the living cells of which they are composed, which constitutes their life, is identical. The necessity for oxygen, the necessity for food, the necessity for reproduction, is the same in each. By altering the means by which these necessities have had to be obtained, a corresponding alteration in structure has been brought about, and thus the survival of the species safeguarded. It is this structural change, in so far as it concerns the pelvic floor, that we have to study. But this by itself can be of little service; to understand the structure in any type we must at the same time consider, as far as we are able, the conditions of the physiological experiment in question, whereby the particular variety of structure has been brought about.

FISHES.

A pelvic floor can scarcely be said to exist in the fish, for the pelvis is rudimentary. In the dog-fish (Fig. 1) the pelvic girdle is represented merely by a transverse bar of cartilage placed just in front of the cloaca. It is unconnected with the vertebral column except by means of that part of the lateral trunk musculature which extends forwards from the tail into the body, and which, as it passes over the pelvic bar, sends a good strand of its lowermost fibres to be inserted into its upper lateral part. This strand of fibres, which forms part of the ventral tail musculature, from which it cannot be differentiated, is directed from behind forwards to the pelvic bar and may be called the *caudo-pelvic strand*. Behind the cloaca it abuts upon the median line and is in apposition with the similar strand of the opposite side. As these two strands are traced forwards to reach the pelvic bar they diverge to allow the cloaca to pass between them, which they thus embrace. So, if a pelvic floor can be described in the dog-fish, it is evidently formed by the innermost margins and adjacent parts of the caudal extensions of the lateral trunk musculatures, which I have ventured to call the caudo-pelvic strands.

This lateral trunk musculature of the fish forms the most conspicuous part of its body. That part of it which forms the musculature of the tail passes in an uninterrupted way to the skull. In the dog-fish it consists of fibres horizontally placed, and is easily divided into two parts—a dorsal and a ventral—by the well-marked lateral line. In front of the pelvic bar, however, the lower part of the ventral musculature, that which encloses the body cavity, is formed of a thin sheet, the fibres of which are obliquely placed. These arise from the connective tissue enclosing the lower longitudinal fibres and pass obliquely downwards and forwards towards the median ventral line. But the fibres which arise from the anterior border of the pelvic bar pass directly forwards. There is no line of demarcation between the oblique fibres and the median longitudinal ones, but the former merge imperceptibly into the latter. The oblique fibres correspond to the internal oblique and the median longitudinal to the recti abdominis muscles of higher vertebrates.

In Protopterus—one of the Dipnoi—the anatomical relations of the cloaca, and the parts immediately behind the pelvic plate, are similar to those found in Scyllium canicula, except that the transformation of the pelvic fins into slender cylindrical processes, and the displacement of the cloacal opening from the median line to the left side, cause corresponding differences. The caudo-pelvic strand of muscle fibres is present on each side. They arise as oblique fibres from the ventral axial skeleton of the tail, and they pass downwards and outwards and forwards, and then inwards to become attached to the pelvic plate and the median line. Anterior to the pelvic plate, they are continuous with a layer of oblique fibres, which passes downwards and forwards, similar to that in the dog-fish, and which takes part in the formation of the ventral body wall. But besides this internal oblique layer, another layer of oblique fibres, directed downwards and backwards—i.e., caudalwards—exists in Protopterus; so that in this vertebrate the abdominal wall consists of two distinct layers, easily distinguished from



each other by the different directions of their fibres, the superficial corresponding to the external oblique of higher vertebrates. A comparison of the ventral abdominal wall of Protopterus with that of the dogfish also shows that the former is not only relatively, but absolutely, thicker than that found in the latter, so that there is not only a structural change in the obliquity of muscle fibres, but also an absolute addition. These external oblique fibres reach as high up as the lateral line from which they arise, and are inserted into the median ventral line; they also extend as oblique fibres into the tail.

It is to be noticed in Protopterus that the fibres of the dorsal part of the lateral trunk musculature are also oblique, not longitudinal as in the dog-fish, their direction being exactly the opposite of those of the external layer of the ventral part. Since the paired fins in Protopterus, on account of their cylindrical form, can scarcely have much, or any, effect in controlling ascent or descent whilst swimming, whatever the cause of the appearance of the external oblique muscles of the ventral wall may be, it seems as though the oblique disposition of the dorsal fibres may have arisen to counteract the effect of the former, and by variations of contraction in each to enable the fish to change its course whilst swimming either obliquely upwards or downwards.

A muscular diaphragm, corresponding to the thoracic diaphragm of mammals, does not exist in the fish; but the region containing the heart is cut off from the rest of the body cavity by the septum transversum.

The cloaca in the fish does not appear to possess a sphincter muscle. Neither in the dog-fish (Fig. 1) and

FIG. 1.

Dissection of cloacal region of the Dogfish. About half life size. P, Pelvic bar bisected and turned outwards. C.P., Caudo-pelvic strand.

Protopterus, nor in the mackerel and herring have I been able to find one. In the former, the caudo-pelvic strands with the pelvic bar or plate appear to serve as a closing apparatus; whilst in the latter, a distinct muscle bundle arises from the median dense tissue and tips of ventral spines immediately behind the cloaca, and passes forwards, one on each side of it, along the median ventral line of the fish. In front of the cloaca these two muscle bundles are united together by connective tissue and on contraction cause a bilateral compression of the cloaca.* But no ring-like muscle exists. It would seem, indeed, that a closure of the cloaca by means of a special sphincter muscle is not so necessary for the fish as it is for terrestrial animals; for fish live in a medium—water—the specific gravity of which is not very different from that of their bodies, and the pressure exerted by this medium on all sides of the animal will tend of itself to prevent an extrusion of any part from within, such as excrement or ova. Their shape, and the compactness of their viscera, are sufficient evidence of this pressure; which varies, of course, with the depth of the fish from the surface, and may be very considerable. In vertebrates, however, which live on the land, and whose bodies, therefore, are surrounded by a medium of a greatly diminished specific gravity, quite different conditions exist; for the medium cannot, because of this physical difference, have the same effect on the contents of the cloaca, around the orifice of which in the great majority of terrestrial vertebrates, a distinct sphincter muscle is to be seen.

When, however, in the dog-fish an escape of visceral contents becomes a necessity, it is plain the pressure bearing upon the cloaca from without, and which opposes such escape, can only be overcome by an increased pressure within—i.e., an increased visceral pressure; for the contents of the viscera can only be expelled by means of a pressure effect, in which the pressure within the oviduct, for instance, becomes greater than that of the medium by which the fish is surrounded. This, in the case of the ejection of excrement, may be met by the contraction of the gut musculature; but such ejection will be more effectual if the body-wall musculature surrounding the viscera, responding by an increased contraction, increases the pressure to which they are already subjected. That such increased visceral pressure, brought about by contraction of the body-wall musculature, is a real factor will, I think, be admitted when it is remembered that the size of the ova passed, at least in the dog-fish, is very considerable (Huxley [16]).† This seems to explain the existence of the oblique fibres in the ventral wall of the dog-fish; for their direction is such that their contraction will determine an increase of pressure towards the cloaca. Such an end as the voluntary increase of visceral pressure, by the increased contraction of the enclosing musculature, would be impossible, or difficult to achieve, or, at least, it would not be so efficiently performed, were all the fibres of the trunk placed longitudinally. The fixation posteriorly of the pelvic bar, which is effected by the caudo-pelvic strands, and the limitation of the size and dilatability of the cloaca, which this fixation causes, may also be a factor, necessitating an increased visceral pressure during the passage of ova; and this is in keeping with the fact that in many of the higher animals, including man, a similar difficulty occurs, constantly during parturition, and commonly during defæcation, and which is certainly not due to the medium in which these animals dwell, but to a very different cause.

In Protopterus, an increased visceral pressure is also necessary during aerial respiration for expiration. It is plain before a fresh supply of air can be taken that the volume of the lungs must be somewhat reduced. This can only be accomplished by a compression of the viscera amidst which the lungs lie, and is produced by the pressure of the medium about the animal, and supplemented by the increased contraction of the enclosing musculatures. In Ceratodus, a dipnoi, which is entirely aquatic, and which only occasionally rises to the surface to breathe—i.e., to swallow air, its blood being oxidised, as in the majority of fish, by means of the well-developed internal gills—the pressure of the water without will probably suffice to effect expiration, when the sphincter of the glottis is relaxed. But when the water drains away from the swampy places in which Protopterus lives, and exposes it to air, and during its long æstivation this force exerted by the water is lost: thus it necessarily follows that the contraction of the enclosing muscles must be increased to obtain the same result as before.

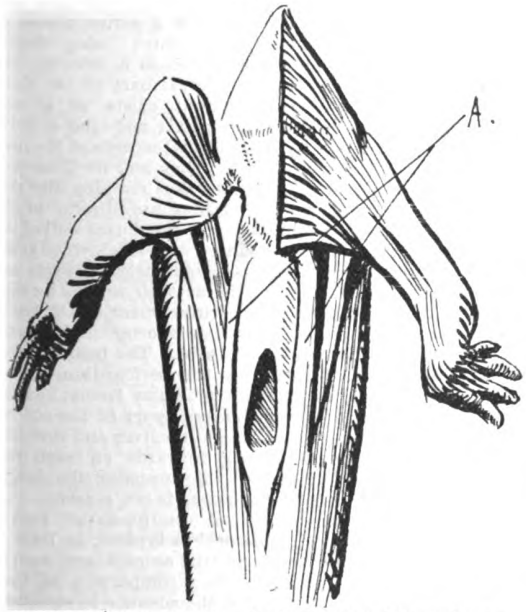
Although the increased thickness of the musculatures enclosing the visceral mass in Protopterus may perhaps be explained by the greater activity necessitated by wriggling movements in partially inspissated mud, the development of an additional muscle layer of oblique fibres, passing downwards and caudalwards seems to have been caused by such a necessity as that of a frequently recurring forced expiration; for the direction of their fibres is such that their contraction will determine an increase of pressure towards the pharynx.

In support of this, we find that whilst in Ceratodus the lung exists as a large unpaired sac, in Protopterus the lungs are paired, their structure much more sacculated and more lung-like, the internal gills have partially atrophied, and the heart has evolved further; and side by side with these visceral changes and different habits, that the ventral wall musculature in Ceratodus shows no trace of the second external oblique layer, which is so conspicuous in Protopterus (Wiedersheim [36]).

Such considerations as these seem to offer adequate explanations for the origin and the marked development in the fish of the caudo-pelvic strands on either side of the cloaca on the one hand and the oblique fibres in the ventral part of the lateral trunk musculature on the other, the essential function of which evidently is to effect an increase of the internal visceral pressure.

AMPHIBIA.

In the amphibia development has proceeded further. A great change has taken place in the pelvis, in that a bony process, the ilium, already present as an outgrowth in some



* See Holl, p. 260, see reference 14.

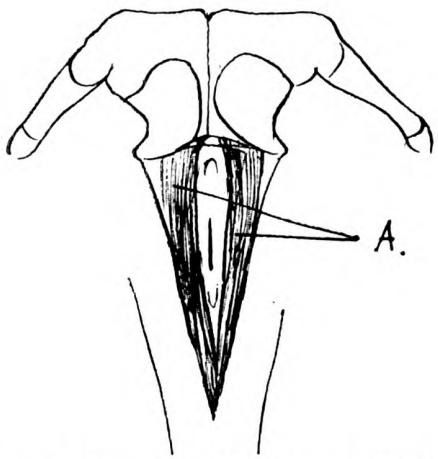
† The superior figures relate to the Bibliography which will be printed at the end of Lecture II.

of the fishes (as in Chimaera monstrosa: Wiedersheim), has grown dorsally on each side from the pelvic plate, passing upwards in the tissues of the lateral trunk wall towards the spine. In some species, as in the Salamander, this ilium has reached and has become attached to the rib of the single sacral vertebra by an articulation, which allows a to-and-fro movement of the pelvis upon the spine; but in others, as in Menobranchus, this upgrowth has remained incomplete, so that the pelvis is freely moveable. It is significant to notice of these two species, whilst the adult form of the Salamander lives entirely on the land and does not possess gills, Menobranchus is wholly aquatic and large external gills are conspicuously present.

Next, dissection shows the existence of a pair of muscles arising from the ventral part of the tail skeleton in the middle line, at some distance from the pelvis, diverging as they pass forwards, one on each side of the cloaca, to be inserted into the posterior edge of the pelvic plate (ischia). (Figs. 2 and 3.) We have here, indeed, the caudo-pelvic strands of the dog-fish, segmented off from the lateral trunk musculature, and in Salamander, forming distinct and individual muscles. But in Menobranchus, whilst these muscles are as distinctly defined anteriorly as they are in Salamander, posteriorly they merge into the ventral tail musculature and thus appear to be continuations of it. Anteriorly these muscles are so placed that their surfaces look upwards and downwards, and their edges laterally, the median borders being only separated from each other by a small interval. As each muscle is traced distally it becomes

FIG. 2.

Dissection of Menobranchus, showing caudo-pelvic muscles A. The cloacal passage has been cut through on a plane with these muscles and the superficial parts have been removed.



twisted on its long axis, so that its superior surface becomes internal, and it thus presents a broad surface to the cloacal passage as it passes by it; at its origin from the tail it is vertically placed, and is contiguous with its fellow of the opposite side.

The abdominal wall in Menobranchus consists, besides the recti, of three distinct layers: an external, the fibres of which pass downwards and backwards or caudalwards; a middle, the fibres of which pass downwards and forwards; whilst the fibres of the innermost layer pass almost directly downwards and inwards, forming the transversalis, which is first met with in the tailed amphibians. It is interesting to notice that the direction of the fibres of the dorsal part of the trunk musculature (that dorsal to the lateral line) is also oblique, the fibres passing downwards and forwards as in Protopterus. In the Salamander the external and internal oblique muscles are well developed, but an inner layer of transverse fibres, corresponding to the transversalis, does not exist. Recti abdominis are present.

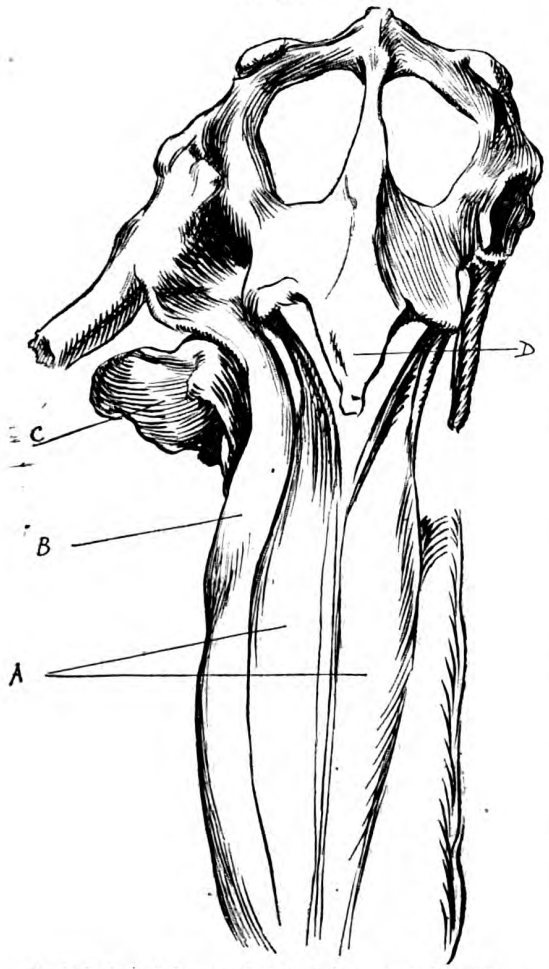
In neither Menobranchus nor in Salamander maculosus have I been able to discover a sphincter cloacæ. Since the Menobranchus is entirely aquatic, the absence of such a sphincter may be more easily understood. Its absence in the purely terrestrial Salamander seems to find an explanation in the well-developed caudo-pelvic muscles. Since these arise from the median line of the tail, and are inserted into the pelvic plate in such a fashion that their inner borders almost reach the middle line, when they synchronously contract, the pelvis being fixed by the recti, they will exert a bilateral compression of the cloaca, and apparently this is sufficient to effectually occlude its passage.

A survey of the conditions found in Menobranchus and the Salamander maculosus seems to show that the evolutionary advance trended towards the fixation of the pelvis to the

FIG. 3.

Dissection of Salamander maculosus to show A, caudo-pelvic muscles.

vertebral column, and that this is associated with greater variations of internal pressure, due to an increase in general activity. The change in the method of respiration, compared with that of the Dipnoi, is not very great. When this is carried out by means of the lungs, the air is forced into them by an act similar to that of swallowing; whilst expiration is effected by an increase of the contraction of the abdominal wall musculature—i.e., by an increase of the internal visceral pressure. Since the recti abdominis and external obliques are attached to the pelvis, their contraction can only become efficient by a fixation of this structure. This fixation was primarily attained by the development of the caudo-pelvic muscles, which thus anchored the pelvis posteriorly. These muscles are relatively of considerable length, and pass caudally from the pelvis almost in the same straight line as the recti abdominis, and thus are admirably adapted to resist a displacement of the pelvis forwards which contraction of the recti tends to bring about. Moreover, since these muscles are attached to the pelvis as broad horizontal bands abutting upon the median line, besides fixing the pelvis, they also prevent the escape of pressure impulses posteriorly; and further, by resisting these impulses, tend to increase the pressure effect. The frequent occurrence of these variations in internal pressure, not only necessary for expiration but also incidental to general activity, and of importance as an accessory circulatory mechanism, is also associated with the further development of the abdominal wall musculature and with the evolution of the caudo-pelvic muscles. Indeed, the correlation of these two factors—the need for an increased visceral pressure on the one hand, and for efficient enclosing muscular walls on the other—is such—the former being so plainly dependent on the latter—that they take on the forms of cause and effect.



REPTILES.

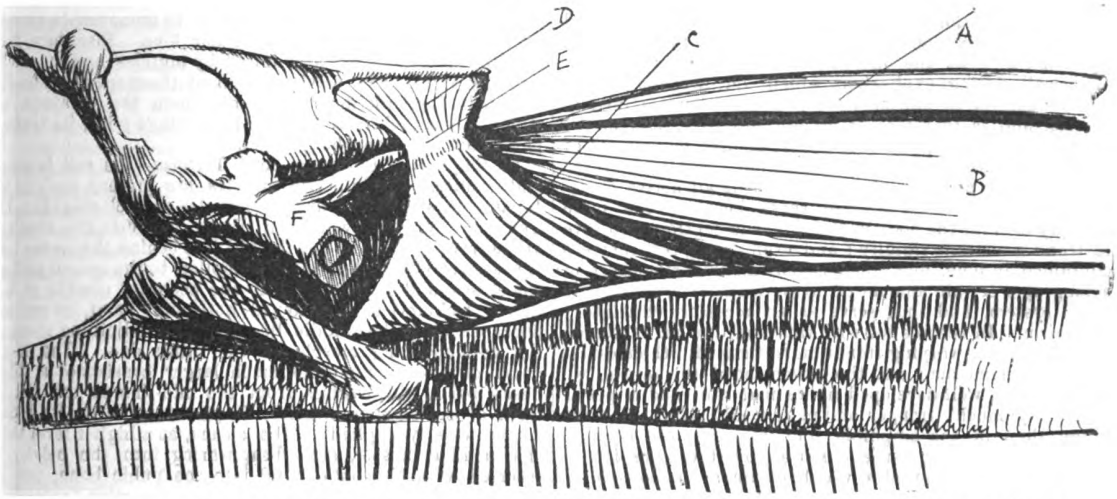
The condition found in reptiles is extremely interesting. At least two sacral vertebræ are present, which are either ankylosed or bound together by fibrous tissue, whilst the fibro-cartilage which connects the ends of their ribs and forms a single broad area for the attachment of the ilium

further restricts any movement between them. This sacro-iliac articulation is placed behind the acetabular joint and may permit a certain amount of a to-and-fro movement of the pelvis on the spine, as in Iguana and Emys, or the pelvis may be immoveably fixed to the spine, as in the Crocodile. The pelvis is completed inferiorly by the junction of the pubic and ischial bones which may form a single median symphysis.

In Iguana the caudo-pelvic muscles are conspicuously present (Fig. 4), but instead of a single muscle two are found on each side, one being much larger than the other (Fig. 6). The larger caudo-pelvic muscles are of considerable length and are superficially placed, one on each side of the cloaca,

FIG. 4.

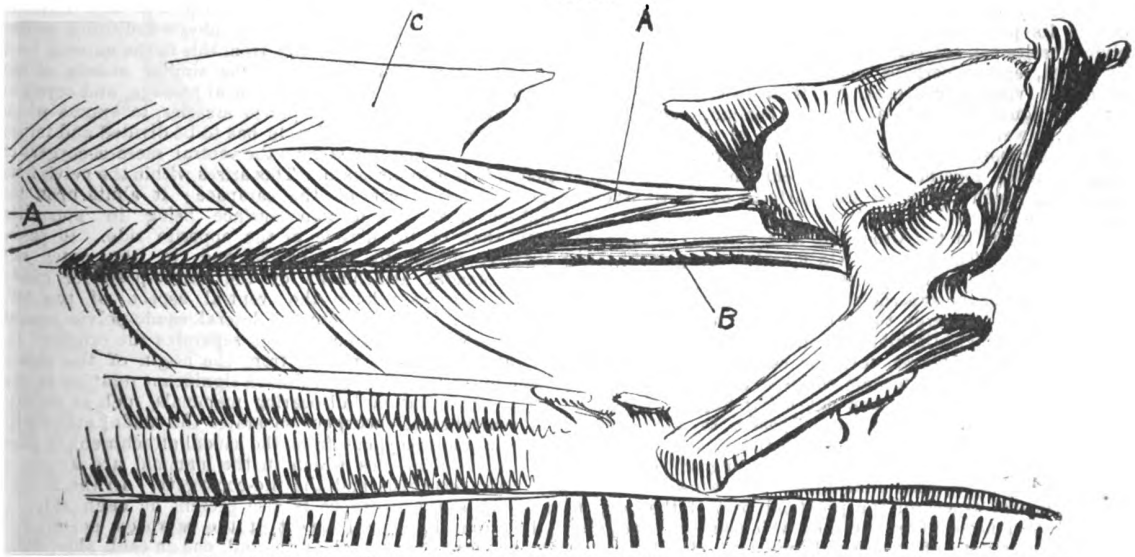
Ventral view of Iguana, showing pelvis. A, A, The large antero-posterior caudo-pelvic muscles. B, The caudo-femoral muscle of the right side attached to femur. C, The sling; the attachment of the sling to the hypo-ischium, D, has been cut through and turned outwards.



behind which their median borders are in apposition, where they arise from the tail by an extensive origin. Traced forwards they rapidly diminish in size and give rise to a tendon which is inserted into a bony protuberance on the ventro-lateral aspect of the pelvis. The much smaller and much shorter caudo-pelvic muscle is placed on the inner and deep side of the larger muscle, which thus hides it from view. It arises from the fascial septum in the angle between the diverging larger caudo-pelvic muscles immediately behind the cloaca, and passes forwards and outwards, crossing the dorsal (deep) surface of the larger muscle, to be inserted into the ventro-lateral aspect of the pelvis, immediately behind the posterior lip of the acetabulum, on a more dorsal plane and more laterally to the insertion of the larger (caudo-pelvic) muscle. The larger and smaller caudo-pelvic muscles are quite distinct from each other, and at their insertions are separated by an interval; but they are so closely related that it seems not unlikely they are differentiated parts segmented off from a single parent muscle.

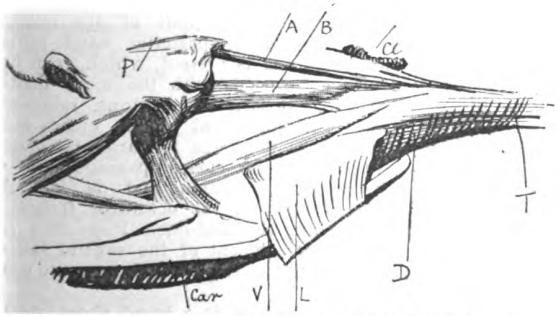
Filling up the big space between the spines of the chevron bones internally and the superficial tail musculature externally, and placed immediately dorsal to the belly of origin of the larger caudo-pelvic muscle which partially hides it from view, is the large caudo-femoral muscle (Figs. 4 and 5), the origin of which reaches anteriorly the caudal limit of the pelvis, and here suddenly passes outwards over a sling to reach and be attached to the upper part of the femur. This sling (Fig. 5), over which the caudo-femoral muscle passes, is formed by a tendon interposed between two muscles—a dorsal and a ventral. The dorsal muscle—which, from its similarity to a muscle found in the Tortoise (Emys) may be called the *lateral caudo-pelvic muscle*—arises from the transverse processes of the anterior caudal vertebræ; its posterior fibres pass downwards and forwards, but its anterior fibres, which form much the thicker part, pass almost directly downwards to end in the short flat tendon forming the sling referred to. The other muscle, which serves to keep this tendon in place, arises from the hypo-ischium and passes outwards and upwards to be inserted into the tendon. Besides retaining the upper part of the caudo-femoral muscle in place, this mechanism, with that of the opposite side, is also capable of exerting a bi-lateral compression upon the pelvic continuation of the body cavity and the cloaca, which is very evident on dissection.

The body wall musculature, in which ribs are embedded, consists, besides the recti, of three layers—the external and internal oblique and transversalis muscle. The ribs pass obliquely downwards and backwards in a series almost as far as the pelvis, the last two or three being short; anteriorly their ventral ends are united to a sternum, but posteriorly they lie freely in the ventral part of the flank musculature. The transversalis muscle exists as a continuous layer placed between the pelvis and the anterior limit of the thorax. It covers the internal aspects of the ribs, ventral to their angles from which it arises, and its fibres pass transversely to the ventral mid-line, thus crossing the ribs obliquely. In the abdomen its relations are similar to the corresponding mammalian muscle. On the dorsal wall of the thorax internally a muscle is present on each side, which arises from the vertebral column and passes obliquely outwards and forwards to be inserted into the ribs at their angles by slips which interdigitate with the slips of attachment of the transversalis, and which gradually become shorter and shorter as the neck is reached (vertebro-costalis). The heart is shut off from the peritoneal cavity by the pericardium and a fibrous septum which may contain muscular tissue, but the lungs lie freely in the dorsal and anterior part of the cœlom, their basal parts related on each side to the liver and stomach, their upper (apical) parts passing forwards on each side of the heart towards the neck. A muscular diaphragm separating the thorax from the abdomen is not present.



A comparison of the anatomical conditions of such a reptile as Iguana (which is more or less typical, at least of the lacertilia) with that of the terrestrial amphibians, such as Salamander maculosa, coupled with a comparison of their habits and mode of life, shows that the advance in structure, which is self-evident, is due to an increase in general activity and to a change in respiration which is correlated with this advance. Owing to the presence of ribs inspiration is effected by a bilateral expansion of the fore part of the trunk (thorax), by which mechanism a much larger quantity of air is caused to enter and distend the lungs than would be possible by the amphibian force-pump action of the mouth and pharyngeal floor alone. That expiration is a muscular act is shown by the existence of the well-marked intra-thoracic muscles (transversalis and vertebro-costal muscles), the function of which plainly is to determine an increase of intra-thoracic pressure, and by causing a diminution of the thorax to result in the ejection of the respired air from the lungs. To this end they are aided by the abdominal wall musculature, which clearly participates in expiration; for unless the visceral pressure in the abdominal region were increased during expiration, increase in the thoracic pressure would as easily cause a displacement of the lungs posteriorly into the abdomen as it would cause the ejection of air anteriorly, and thus be only partially effective. Indeed, as we ascend the vertebrate series we find the lungs, which in the Dipnoi

FIG. 5.



Dissection of Iguana from right side showing A, large antero-posterior caudo-pelvic muscle; B, caudo-femoral muscle and sling in position. The sling consists of a dorsal muscle, C, lateral caudo-pelvic muscle, and a ventral muscle, D, arising from hypo-ischium, and an interposed tendon, E. F, Femur with attachment of caudo-femoral muscle.

FIG. 6.

Dissection of Iguana from the left side. The sheet of superficial tail musculature, C, has been cut through and turned upwards with the large antero-posterior caudo-pelvic muscle, A, to which C is attached, by which means the small antero-posterior caudo-pelvic muscle, B, is displayed. The lateral caudo-pelvic muscle, the caudo-femoral muscle, and the femur have been removed.

FIG. 7.

Dissection of Emys from right side. P, Pelvis. Cl, Cloaca. T, Tail. A, Small ventral antero-posterior caudo-pelvic muscle (attached to pelvic outlet ischium). B, Large dorsal antero-posterior caudo-pelvic muscle (entering pelvis to be attached to pelvic inlet ?). L, Lateral caudo-pelvic muscle cut through at the ventral attachment and turned outward. V, Ventral sacro-coccygeus. D, Dorsal sacro-coccygeus muscle. Car, Carapace.

FIG. 8.

Dissection of Emys from left side showing the lateral caudo-pelvic muscle, L, in its natural position enclosing the cloaca, the antero-posterior caudo-pelvic and ventral sacro-coccygeal muscles. D.S.C., Dorsal sacro-coccygeus. V.S.C., Ventral sacro-coccygeus.

and Amphibians extend throughout the cœlomic cavity, are bodily compressed more and more anteriorly, until finally they become entirely thoracic organs. This change in position, presumably, is to be attributed to the aspiration of the thorax during the reptilian inspiration and to the increasing activity of the abdominal wall during expiration, which, on account of the greater quantity of air inspired, is necessarily amplified in Reptiles, and is therefore of greater intensity than in the terrestrial amphibians—that is to say, greater increments of internal pressure occur during expiration. Similar increase of the internal pressure also occurs during all active movements; for the more intense these become, the more necessary is it for the body wall muscles to contract and give the trunk a certain rigidity; and even during rest they are maintained in tone, and probably play an important part in keeping up a certain amount of pressure upon the splanchnic venous system, and thus serve as an accessory circulatory mechanism. In accordance with this need for an increased internal pressure, varying from time to time with the requirements of the moment and the movement of the animal, we find not only a well-developed abdominal wall and a pelvis structurally much stronger and more firmly attached to the sacrum than in the amphibia, but also a more efficient closure of the pelvic outlet assured by the conspicuous lateral caudo-pelvic muscles, which compress the post-pelvic part of the body cavity and the cloacal passage from side to side. The antero-posterior caudo-pelvic muscles in Iguana clearly serve as a fixatory apparatus for the pelvis and thus form the structural basis for the effectiveness of the contraction of the body wall muscles, a fact which demonstrates the necessity for a tail rigid in the dorso-ventral plane, at least in its proximal part. These antero-posterior caudo-pelvic muscles can scarcely exert much or any pressure upon the cloaca, except perhaps when this is distended by the passage of visceral contents, for their insertion into the pelvis (in Iguana) is lateral and not median. The cloaca, however, is well guarded by the two bow- or crescent-shaped muscles, disposed transversely, the one in front, the other behind; these together form an efficient sphincter for its orifice, which opens on the surface as a transverse slit.

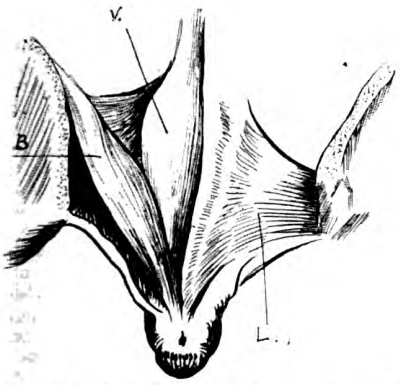
The condition in the Crocodile is essentially similar to that in Iguana. The caudo-pelvic muscles are present, but do not form such fleshy bellies as in Iguana; they appear rather as parts of the superficial tail musculature, the ventral fibres of which converge to be inserted by a small attachment into the pelvis (ischium) much nearer the middle line than in Iguana. Moreover, only one caudo-pelvic muscle is present on each side, a muscle corresponding to the smaller caudo-pelvic muscle of Iguana not being found. They are entirely muscular, and the cloaca passes to the surface between them. They cover an enormous caudo-femoral muscle, which passes outwards over a sling to reach the femur as in Iguana. This sling arises by means of a fascia from the lateral aspect of the proximal part of the tail; it gives rise to muscle fibres, most of which are inserted into the distal extremity of the ischial symphysis, in close relation with, and immediately ventral to, the attachment of the caudo-pelvic muscle; whilst others are inserted into a raphe which extends from the symphysis to the anterior part of the cloaca, which opens as a longitudinal slit just behind the symphysis.

Since the Crocodile presents a more advanced structure than in Iguana—in that the interventricular septum (of the heart) is complete, whilst in other reptiles it remains incomplete—it may be questioned how it is that the caudo pelvic muscles are less differentiated and less prominent than in Iguana. The answer seems to be that their function in part has disappeared, since the pelvis in the Crocodile is completely ankylosed to the spine, whilst in Iguana it is still mobile to some extent. Thus they are no longer required for its fixation, and presumably only exist to prevent the escape of pressure impulses from the pelvis. Moreover, they are attached to the pelvis much nearer the middle line than in Iguana, and they therefore exert more influence over the cloaca, which, however, is provided with sphincter muscles. To this end they are aided by the lateral caudo-pelvic muscles, which correspond with the similar muscles in Iguana.

The condition in the Tortoise is somewhat different from that in Iguana, owing to the fact that the body is encased in a shell, the ventral part of which—the plastron—is united on each side in the region of the "bridge" to the dorsal part—the carapace—either by ligament, as in Emys, or by a suture, as in Testudo, in which, therefore, it is immoveable except for a transverse hinge in its posterior lobe. Elsewhere, the plastron and carapace are united by muscles and the thick leathery skin. The pelvis in each of these species is freely moveable, forwards and backwards, upon the carapace, to which it is attached by the ilia by a hinge joint, its ventral part being free from the plastron.

In Emys—the European Pond Tortoise—the tail is short and slender. Caudo-pelvic muscles are present and, as in Iguana, consist of two distinct muscles on each side (Fig. 7). The more ventral, which in Emys is much the smaller, arises from the mid-line of the tail just behind the cloaca; as it passes forwards it is closely applied to the lateral wall of the cloaca, and is inserted into the posterior margin of the pelvis (ischium) as a flattened horizontal band, its median fibres reaching the middle line and thus adjoining those of the corresponding muscle of the other side. The more dorsal caudo-pelvic muscle, much larger, consists of a thick fleshy band, which arises from the mid-line of the tail in front of the smaller muscle. It passes forwards, its broad surface closely applied to the cloaca, at a higher level than the smaller muscle, and, disappearing into the pelvis, is inserted as a horizontal band into the pubic bone, just in front of the obturator foramen, its insertion extending from just outside the median line to the lower part of the ilium.

On each side of the root of the tail, arising from its lateral aspect, is a sheet of muscle—the lateral caudo-pelvic muscle—the fibres of which pass downwards and forwards and are inserted into the ischial symphysis and into a median raphe which extends distally from this to the anterior limit of the cloaca (Fig. 8). With the similar muscle of the opposite side it encloses the cloacal passage, and covers in the antero-posterior caudo-pelvic muscles, to expose which the lateral caudo-pelvic muscle has to be divided and turned outwards. When this is done the ventral sacro-coccygeus of that side is also disclosed. This arises within the pelvis from the ventral aspect of the carapace; it abuts upon the middle line, its median surface being in apposition with that of the muscle of the opposite side. It passes distally, dorsal to the cloaca and to the outer side of the caudal attachment of the antero-posterior caudo-pelvic muscles, along the ventral aspect of the tail. Laterally, it is related to the lateral caudo-pelvic muscle. Thus the ventral sacro-coccygeus separates the origin of the lateral caudo-pelvic muscle from the origin of the antero-posterior caudo-pelvic muscles—a significant relation in view of the fact that in tail-bearing mammals, such as the dog, the ventral sacro-coccygeus separates the caudal attachment of the ischio-coccygeus from the caudal attachment of those caudo-pelvic muscles which in the mammal are known as the pubo-coccygeus and the ilio-coccygeus. In the Tortoise a dorsal sacro-coccygeus is also present on each side. It arises from the ventral aspect of the carapace, posterior to the pelvis, and passes along the tail, one on each side, dorsal to the origin of the lateral caudo-pelvic muscle; just as the dorsal sacro-coccygeus in the dog, for instance, similarly passes dorsal to the caudal attachment of the ischio-coccygeus in that animal.



In Testudo the tail is shorter but stouter than in Emys, ceasing just beyond the posterior limit of the cloacal aperture. Instead of two antero-posterior caudo-pelvic muscles on each side, only one is present, which, from its attachments, evidently corresponds with the more dorsal muscle in Emys (Fig. 9). It is a broad, stout, muscular band, and arises from the tail dorsal to the cloaca and anterior to its aperture; as it passes forwards its broad surface is closely applied to the cloacal passage; reaching the pelvis it disappears within and is inserted into the pubic bone in front of the obturator foramen, its innermost fibres reaching the mid-line. Posteriorly, it is related to the caudal attachment of the ventral sacro-coccygeus, the majority of its fibres passing internal to that muscle.

The lateral caudo-pelvic muscle is a broad sheet, much more extensive than in Emys. It arises by a wide origin from all the coccygeal vertebræ, anteriorly from the ventral mid-line, but posteriorly from the transverse processes. From this extensive origin the fibres converge towards the

ischial symphysis, the majority being inserted into it posteriorly by muscle; anteriorly, the attachment of the muscle is continued by an aponeurosis which reaches half way along the pubo-ischial symphysis.

It is unnecessary to go into detail in considering the mode of life of these interesting animals. Just as in Iguana, the necessity for an increased visceral pressure is clearly evident in the Tortoise, in which the act of expiration is performed by the contraction of the body wall musculature. Indeed, the complete surrounding of the visceral mass by muscular sheets and dermal bones, and the complete enclosure of the cloacal passage and occlusion of the pelvic outlet by the muscles attached thereto, leave no doubt in the mind that the mechanism necessary for causing a marked and repeatedly recurring increased visceral pressure is adequately, indeed abundantly, provided for. Whilst the antero-posterior caudo-pelvic muscles, in virtue of the fact that they arise and are inserted into or near the mid-line of the body, can cause a bilateral compression of the cloaca by their simultaneous contraction, the pelvis being fixed (by the body wall muscles), this is also provided for by the remarkable development of the lateral caudo-pelvic muscles, which completely

FIG. 9.

Dissection of Testudo, ventral view. The pubo-ischial symphysis has been divided, and each half of the pelvis widely separated. B, Antero-posterior caudo-pelvic muscle attached to pubis (pelvic inlet). V, Ventral sacro-coccygeus muscle. Both these muscles have been removed on the left side so as to completely display L, the lateral caudo-pelvic muscle.

enclose the cloacal passage as it passes from the pelvic cavity to its exit. This post-pelvic mechanism is sufficient, as an inspection of the dissected animal will convince one, to completely obstruct the escape of pressure impulses caused by a contraction of the body muscles, and by this obstruction to add to the pressure effect. In this connexion it is interesting to reflect upon the increased perfection of the pelvic closing apparatus, which has occurred in Testudo, for it is significant to find that whilst Emys is aquatic Testudo is a terrestrial tortoise, and again the influence of the medium is felt. Whilst the small, more ventral, caudo-pelvic muscle in Emys—in which species it is already a diminutive muscle—has disappeared in Testudo, the other antero-posterior caudo-pelvic muscle (pubo-coccygeus) is much increased; but besides, the lateral caudo-pelvic muscle has greatly developed and ensures more than ever a protection against the escape of pressure impulses from within.

Flexion of tail.—It may be supposed that the antero-posterior caudo-pelvic muscles (pubo-coccygei) of the Tortoise function solely as flexors of the tail; but in face of the shortness of the stumpy tail of Testudo, already flexed by its skeleton so that it cannot be extended, and the comparatively enormous development of its muscles, this can scarcely be maintained. That the muscle may cause a greater flexion of the tail in Testudo than exists during rest is very probable; indeed, by such increased flexion the pelvic outlet may be efficiently occluded—a use the tail is put to in mammals. According to Gadow, Tortoises use their tails for digging holes in the ground into which they lay their eggs. The caudo-pelvic muscles (pubo-coccygei) probably are useful for this and thus act as flexors, since they are attached to the less proximal rather than to the more proximal caudal vertebræ; but, associated with the flexibility of the tail, it is significant to find a pair of new muscles has arisen in the Tortoise—the ventral sacro-coccygei. These, which are not present in the Lacertilia, Crocodilia, nor in Salamander maculosa, presumably are the real tail flexors, for both in Emys and Testudo they are larger than the pubo-coccygei—and in Testudo considerably larger—and, moreover, they pass distally into the tail beyond the attachment of the pubo-coccygei.

Even though it be admitted that the caudo-pelvic muscles may function as flexors of the tail in the Tortoise it is clearly impossible for them to do so in the Lacertilia and Crocodilia, for whilst the tail in all these can be bent laterally with ease and efficiently, in none does flexion, at least of its proximal part, occur—the body is so little elevated from the ground by the shortness of the legs and the tail is so long that this is obvious. The great movement of the tail in these reptiles (Lacertilia, &c.) is its abduction, caused by the conspicuously developed caudo-femoral muscles. In the Lizards it seems as though a tail, rigid in the dorso-ventral plane in its proximal part, is a necessity to allow varying pressure conditions to be produced within the body cavity by giving a firm and fixed origin upon which the caudo-pelvic muscles can contract and thus fix the moveable (reptilian) pelvis. But when the fixation of the pelvis to the vertebral column had occurred the necessity for a rigid tail disappeared, and thus in mammals especially the tail is markedly flexible. In the Tortoise the tail is also flexible, and further, in Emys and in Testudo the pelvis is moveable forwards and backwards upon the carapace. But here we have different conditions, for the production of the variations of visceral pressure, and their purposeful application, do not depend upon fixation of the pelvis, either directly to the spine or indirectly by means of a rigid tail. But besides the contraction of the muscles enclosing the visceral mass (transversalis abdominis, which is attached to the pubic bone), the production of an increased visceral pressure is facilitated by the presence of the plastron. Contraction of the transversalis *plus* contraction of the collective caudo-pelvic muscles will cause an increase of visceral pressure; this will be transmitted forwards towards the anterior limit of this muscular sheet, and will then impinge directly upon the central part of the plastron, against which the visceral mass abuts without the intervention of muscular tissue; and this, being maintained in position by its bony fixation, or by the muscles passing between it and the carapace, will prevent the escape here of pressure and thus lead to the effectiveness of the movement in question.

The existence of the plastron in Emys and Testudo has obviated the necessity for a fixation of the pelvis, for it prevents a spherical form of the visceral mass being caused by the contraction of the inner body musculature and the rotation forwards of the pelvis which the slender and flexible tail of Emys could scarcely prevent. Thus, in these species of Tortoise we have simultaneously a flexible tail and a moveable pelvis, a combination which, as far as I know, exists in no other species of vertebrate.

In conclusion, then, we may say that a study of the anatomical conditions found in the fish, amphibia, and reptiles shows the increasing need for the production of a varying internal visceral pressure, necessary not only for the functioning of the posterior end of the body, but also for the repeatedly recurring act of expiration, and which plays a part of an important accessory circulatory mechanism, and, moreover, occurs incidentally during activity. This necessity has been met by the gradual evolution of the pelvis and of the muscles enclosing the visceral mass, of which muscles those occluding the pelvic outlet plainly form an integral part. The development and segmentation of the antero-posterior and lateral caudo-pelvic muscles is to be attributed to this necessity, for we can only regard their existence as a structural means to meet this demand for an internal pressure—that is to say, they exist for a pressure effect.

LIST OF ANIMALS DISSECTED FOR LECTURE I.

Fish.—Dog-fish (*Scyllium canicula*). Mackerel (*Scomber scombrus*). Herring (*Clupea harrengus*).

Dipnoi.—Mud-fish (*Protopterus annectens*).

Amphibia.—Menobranchus lateralis, s. Necturus maculatus. Salamander (*Salamandra maculosa*).

Reptiles.—Iguana, and several other lizards. Crocodile (*Crocodilus*). Tortoises (*Emys and Testudo*).

A CONTRIBUTION TO THE HISTORY OF INJECTIONS OF SOLUTIONS OF RADIUM.

BY DR. LOUIS WICKHAM,
DIRECTOR OF RESEARCH IN SURGICAL PATHOLOGY AT THE RADIUM LABORATORY IN PARIS;
AND
M. DEGRAIS,
CHEF DE LABORATOIRE AT THE HÔPITAL ST. LOUIS
(*Translated for* THE LANCET.)

SOME very remarkable investigations were made during the past year by Radcliffe Crocker, Chevrier, Dominici, Jaboin, Petit, and Renon, in reference to the injection of salts of radium, and the subject has been discussed at the recent Congress of Physiotherapy. We have always thought that such researches were of great interest, both scientific and practical, and for this reason we have made various experiments directed to this end ever since the establishment of the Radium Laboratory in 1906. At that time nothing seemed to have been published on this subject, at least in France, except an important work by Bouchard, Curie, and Balthazar (Congress of Medicine held at Lisbon in April, 1906). This communication might be summarised as follows.

"When introduced into the animal body the emanation diffuses itself throughout the structures and may in this manner reach deep-seated parts. It has a predilection for the glands which form an internal secretion, and especially for the suprarenal capsules. It is eliminated by the lungs and the skin, and to a small extent by the kidneys."

We wish in this short communication to supply some details of our own experiments, as well as of the observations which they have suggested to us. In a case of lupus vulgaris of the neck a curative change was produced by injections of either (1) water rendered radio-active[1] (radio-activated water) in the proportion of one milligramme of pure sulphate of radium per litre, or (2) water impregnated with radium (radiferous water) in the proportion of one milligramme of pure bromide of radium per litre. In this case 40 injections of each kind (and of one to two cubic centimetres) were given in the course of two months. We said at the time that a new path of investigation was thereby opened up, a path which gave a promise of important therapeutic results because the radio-active energy could be made to penetrate all parts of the body. The patient was shown at a meeting of the Dermatological Society in November, 1906. Another case of lupus, but of the fixed erythematous type, which had been treated by injections of radium from Nov. 2nd to 14th, 1906, was also shown at a later meeting of the same society.

For purposes of comparison we treated in this case the lesions of lupus on the left side by the application of radium apparatus and the lesions on the right side by injections, the results being as follows. On the left side there was sharp reaction, with destruction of the lupus and a subsequent process of repair. On Jan. 16th, 1906, the cicatrix had a very good appearance and seemed to be strong, but on June 22nd, 1907, there was recurrence of the disease at the margin of the tissues of repair. On the right cheek, the side on which injections had been given, there was no visible inflammatory reaction, but there was first a diminution and then a disappearance of the erythema of the lupus, the part assuming a whitish cicatricial aspect. On June 22nd, 1907, when we found the recurrence on the left side, the condition of recovery on the right side was maintained, and there has been no reappearance of lupus there since that time. As we have said in our "Traité de Radiumthérapie," pp. 11, 96, and 275, this was an interesting observation, inasmuch as it seemed to show the superiority of the injections, but the result will be of value only if it is confirmed by other facts of the same kind.

[1] It is well known that the gaseous emanation which escapes from radium at the same time as the rays has the property of conferring some of the properties of radium on the various media with which it comes in contact. These media are thereby rendered radio-active (by *induced* radio-activity), but only for a time, because the properties in question are merely borrowed. For example, insoluble sulphate of radium kept for a time in vaseline or in water renders them radio-active, so that after the removal of the radium salt the vaseline continues to be phosphorescent and the water to be radio-active.

In the preceding cases the doses of radium were extremely small, but they contained the *emanation*, an element which is not present in the rays emitted by the radium apparatus. This emanation is endued with an energy which possesses evident bactericidal properties, as we showed in 1906 in our researches on the action of solutions of radium on cultures of the gonococcus and staphylococcus.[2] The injection of certain insoluble salts of radium suspended in an emulsion into structures of small absorbent power prolongs the contact of the salt with the diseased tissues and intensifies the action of the radiations and of the emanation. In June, 1909, when a large cancerous nodule of the breast was to be treated we endeavoured to put this idea into execution as follows. On our request M. Jaboin, the chemist of our Radium Laboratory, whom we have to thank for preparing these liquids (and to whom, as well as to M. Baudoin, we are indebted for the radio-active analysis of urines to be mentioned presently), made for us an emulsion of radium in a mixture of paraffin and vaseline. Our object was to inject this preparation beneath the nodule so as to form a stratum underlying the whole of the diseased part. When this was done we applied radium apparatus above the nodule so that the latter had the paraffin on its underside and the radium apparatus above, being thereby exposed to a cross-fire to which, for various reasons, we attach importance. The nodule diminished in size and disappeared rapidly; there was no ulceration and there has been no recurrence. This isolated case is not conclusive, but it represents a new technique and a new application of the method of injections.

It may be interesting to know the manner in which the organism behaves towards solutions containing soluble salts of radium (*solutions radifères*). The following observations were made on a series of 30 patients in the wards of one of us (Dr. Wickham) in the Hôpital St. Lazare at the beginning of the year 1908. The solutions that were used consisted of grey oil made with 20 per cent. of mercury and containing a radium salt to the amount of 0·0005 of a milligramme or half a microgramme,[3] according to the accepted unit of quantity. The syphilitic patients received the series of injections in accordance with the ordinary method of mercurial treatment and did not experience any inconvenience. The series consisted of six injections of seven drops each every five days. The analysis of the urines which was made for us led to the following results. After injections of grey oil containing radium (*radifère*) the urine is radio-active during the first three or four days, and its radio-activity decreases with some regularity during that period, a result which agrees sufficiently well with the law of decrease of induced radio-activity. It must be understood that soluble radium when injected is in the free state in the animal body, and carries with it its gaseous emanation which gives rise to the phenomena of radio-activity. The emanation is only emitted when the salt is in the free state; the salt in a radium apparatus does not supply emanation for therapeutic purposes, for this gas does not pass through any solid body, being in this respect unlike the extremely penetrating radium rays. When after some days the mercury begins to appear in the urine the latter no longer shows radio-activity.

We may mention that we have treated some very anæmic patients suffering from cancer with a series of five injections of soluble salts of radium to the amount of 10 microgrammes per injection. The results have not been without interest, the red globules increasing in number, but the cases are too recent to justify the drawing of definite inferences. These injections were perfectly supported.

In conclusion, we think that these studies have a great interest and ought to be seriously taken in hand.

[3] One microgramme represents the thousandth part of one milligramme.

LITERARY INTELLIGENCE.—Messrs. Shaw and Sons of Fetter-lane, London, are publishing a large work entitled "The Diseases of Infants and Children," by Dr. Edmund Cautley, senior physician to the Belgrave Hospital for Children, London. It consists of 1040 closely printed pages, and the price is 27*s.* 6*d.* net. The same firm is calling attention to a new edition of a book published by them last year, entitled "Symptoms and their Interpretation," by Dr. James Mackenzie. This book we favourably reviewed in THE LANCET of Sept. 4th, 1909.

THE SYSTEMATIC INVESTIGATION OF CHRONIC AFFECTIONS OF THE STOMACH AND INTESTINES.

BY GEORGE HERSCHELL, M.D. LOND.

IT is a peculiarity of diseases of the stomach and intestines that from a study of the symptoms alone we are only able to divide them into groups the members of which, although apparently similar, depend upon widely differing conditions. The differentiation between these cannot in most instances be made by the ordinary methods of physical examination such as palpation, auscultation, and percussion. We shall require in most cases data which can only be acquired by other and more thorough methods of investigation.

It is doubtless true that we can often make a shrewd guess as to the real state of affairs by a careful study of the evolution of the disease and of the symptoms actually present; and this probability may be strengthened by the presence or absence of local tenderness, rigidity, tumour, or other signs which we may discover by a manual examination of the abdomen. But to make a real diagnosis with any degree of certainty we require additional information which can only be obtained by an examination of the stomach contents, stools, or urine.

It must, nevertheless, be understood very distinctly that it is not my intention to under-estimate the information to be derived from the anamnesis—i.e., the scientific questioning of the patient as to his previous history, the evolution of the disease, and the character of the symptoms. On the contrary, nothing can be of greater value as establishing the probability of the nature of the affection from which the patient is suffering. But we establish probabilities only, and the tentative conclusion at which we arrive requires to be confirmed by observed facts before it can aspire to the dignity of a diagnosis or definite opinion as to the nature of the disease. It is quite true that in cases of moderate severity and short duration we may be satisfied with such a tentative opinion, which may be confirmed by the happy result of treatment based upon the assumption. It is, unfortunately, also the fact that in daily practice such an assumption is frequently all that we are able to obtain, whether from the unwillingness or the inability of the patient to undergo a proper examination, and we have to do the best we can with it. But in all cases which are prolonged and resist treatment based upon the hypothesis which we have made, all cases accompanied by loss of flesh which cannot be accounted for by restriction of diet, all cases evidently progressive, and all gastric affections of any duration which occur in middle-aged persons of good previous health, it is our duty to impress upon the patient the absolute necessity for permitting a thorough investigation to be made. We must ever bear in mind that cancer of the stomach is the most frequent form of cancer, and that any dyspepsia which occurs in a man at the cancer age is very probably malignant. In fact, we may take it as a general working rule that any dyspepsia of severity accompanied by loss of appetite in a man between 40 and 60 is due to some serious organic lesion and that no sacrifice of time or convenience can be too great to have the matter settled before it is too late.

The aim of the present paper is to present to the physician who has acquired all the information possible from the anamnesis and the examination of the patient in his consulting room the additional data which modern methods enable him to obtain, and to critically discuss their value from a diagnostic standpoint.

We are able to ascertain the following facts: the length of time taken by the food to traverse the alimentary tract before it is expelled from the body; whether the fasting stomach is empty or contains substances which may afford us diagnostic information; to what extent digestion takes place in the stomach and how long food remains there; whether the pancreatic and biliary secretions are normal; whether there is evidence of chronic pancreatitis or of any affection of the bile-ducts; the presence of catarrh or abnormal putrefactive processes in the intestine; and whether there is bleeding into any part of the gastro-intestinal tract. These are the ordinary points upon which it is often necessary to be informed, and one or more of them may give us the additional data which we require to elucidate the case under consideration. Under conditions of especial difficulty we may not only have to put the patient through the whole series of tests but also to make use of the Roentgen ray, sigmoidoscope, gastroscope, examine the blood, or employ Salomon's test for malignant ulceration of the stomach.

I propose to discuss these points *seriatim* and to point out very briefly what we may learn from their investigations.

A.—The Time taken by the Food to Traverse the Gastro-intestinal Canal.

This may be estimated either by following the shadow of a bismuth meal upon the radiographic screen or by administering a dose of some inert colouring matter, such as carmine or vegetable charcoal, and observing when it appears in the stools. The radiographic method is unfortunately only at the disposal of those medical men who, living in large centres, have access to a properly equipped radiographic laboratory and to whose patients the question of expense is not important; or to the fewer number who have an installation in their house and the technical knowledge to use it efficiently. The charcoal or carmine capsule, besides being of universal application, will often reveal much more than the Roentgen rays, and must eventually be used in many cases.

Surprisingly little study has been accorded in this country by diagnosticians to the actual time taken by the food to pass through the alimentary canal, considering that its clinical importance is just as great as the daily number of stools. For instance, it is not at all unusual for a patient to have one stool a day and in consequence consider the bowels to be regular, whilst all the time there is a latent constipation with retention of fæcal matter, giving rise to chronic ill-health from auto-intoxication.

(*a*) In cases of diarrhœa the passage of the charcoal in the normal time would tend to show that the peristalsis in the small intestine was not increased and that the disturbance was in the lower portion of the large intestine.

(*b*) In diarrhœa the quick appearance of the charcoal or carmine in the stools would suggest that the trouble was in the small intestine or ascending colon.

(*c*) In a patient who has daily motions a dose of charcoal given at breakfast should appear in the next morning's stool. If it fails to do so there is latent constipation. If after the stool lavage of the sigmoid brings away black fæces there is retention in the lower bowel. If it does not do so the delay is in the cæcum, ascending, or transverse colon.

(*d*) In a patient who does not have a daily motion the removal of black fæces by lavage of the sigmoid on the morning following the administration of the cachet would show that atony or dilatation of the lower bowel was an important factor in the production of constipation.

(*e*) Appearance of black stools for several days after the administration of a dose of charcoal will point to atony of the bowel and latent constipation.

(*f*) By administering a dose of charcoal or carmine at the commencement of a test intestinal diet, we are able to mark off the moment when it commences to appear in the stools, and when we may safely use them for purposes of examination.

(*g*) We may mark off and obtain the total fæces corresponding to a test diet extending over a fixed period by giving a carmine cachet at its commencement and termination (provided that there is no latent constipation).

B.—The Examination of the Fasting Stomach.

This is especially useful as a first step in the investigation of cases in which there is a suspicion of serious disease. Not only shall we obtain valuable information as to the motor functions of the stomach, but even possibly special indications which the chemical examination of a test meal cannot afford.

With respect to the results obtained by this examination, we may divide our cases into four groups: the stomach may be empty; it may contain neutral or alkaline contents; it may contain hydrochloric acid; or there may be present lactic or organic acids. Each of the last three groups may be again subdivided into those which contain food residues and those which do not.

1. *The stomach is empty.*—We are justified in arriving at the following deductions. (*a*) There is no considerable motor insufficiency of the stomach, as we know that the

stomach is able to empty itself in 12 hours. In order to ascertain whether a lesser degree of loss of motility is present we must examine the stomach six hours after a mixed meal. We can thus practically exclude pyloric or duodenal stenosis. (*b*) We can exclude permanent hypersecretion of gastric juice, and thereby probably gastric duodenal ulcer. Consequently, any excess of HCl which we may find in our subsequent investigation must be alimentary—that is, limited to the digestive period. (*c*) We can probably exclude cancer of the stomach.

2. *The fasting stomach contains a small quantity of neutral or alkaline fluid with or without pus, blood, or infusoria.*—(*a*) A simple neutral or alkaline fluid containing epithelium and a few leucocytes would suggest achylia gastrica or chronic gastritis. (*b*) If pus and blood are present and if we can exclude phlegmonous gastritis (an affection of great rarity) and pus from the mouth, tonsils, post-nasal space, or bronchi there is in all probability an ulcerating cancer of the stomach. There must, of course, be an ulcerating surface to produce the pus or blood, and a non-malignant ulcer would hardly be found except in association with hydrochloric acid. (*c*) The presence of infusoria in addition would make our diagnosis practically certain, and we should also be in a position to say that the cancer was situated upon the wall of the stomach and not at one of the orifices. Two varieties of protozoa are found in the stomach—the *trichomonas hominis* and the *megastoma entericum*—when the four conditions are present which are necessary for their existence. These are absence of HCl, an alkaline reaction, pouches or folds in the gastric mucosa, and absence of fermenting food residues. These conditions are only present in interostial carcinoma of the stomach.

3. *The stomach contains hydrochloric acid.*—There may be no remnants of food or macroscopic or microscopic food residues.

(*a*) There are no food residues. If the hydrochloric acid is small in amount and only occasional the stomach is probably normal, as the secretion may be quite accidental and due to some temporary irritation or psychic excitation of the gastric glands. If the hydrochloric acid is invariably present or in larger amounts there is hypersecretion of gastric juice. Such a condition may be rarely a neurosis, or more probably due to ulcer of the duodenum or the irritation of gall-stones or of a diseased appendix.

(*b*) Hydrochloric acid with macroscopic food residues nearly always denotes an ulcer of the stomach or duodenum which has produced some amount of pyloric stenosis.

(*c*) Hydrochloric acid with microscopic food residues. Whenever hydrochloric acid is found in the fasting stomach the problem is to say whether we have to do with a simple hypersecretion of central or reflex origin or one due to the local irritation of retained food residues. The absence of macroscopic food residues is far from being conclusive that food is not retained abnormally in the stomach. Sarcinæ and yeast cells in chains or budding are in themselves strong presumptive evidence of food stagnation. If in addition we find muscle fibres, starch granules, fat globules, or crystals we can be certain that there are food residues retained in the folds and rugæ of the stomach, possibly slight in amount, yet sufficient to set up hypersecretion. Sarcinæ are practically never found in the stomach unless there is hydrochloric acid, and denote either benign stenosis of the pylorus or a carcinomatous ulcer in the early stage before the secondary gastritis has made much progress. As the atrophic changes develop in cases of cancer there will be observed a gradual diminution in the hydrochloric acid and sarcinæ with a proportionate appearance of the long bacillus and lactic acid. Consequently, if we find both degenerated sarcinæ together with the long bacillus we may deduce that the cancerous process is a rapid one. As sarcinæ require some time to grow their absence does not exclude stagnation of short duration.

4. *We find food residues with the presence of lactic acid and possibly the Oppler-Boas or long bacillus.*—A practised observer can usually tell as soon as he looks through the microscope whether the gastric stagnation is associated with the presence of lactic or of hydrochloric acid respectively. In both cases you will see the same changes in the muscle fibres, in both you will often find yeast cells in chains, but if lactic acid be present the protoplasm of the leucocytes will be shrunken and granular, the cells still retaining a faint definite outline; if HCl is present the leucocytes will be entirely digested, leaving only centrally grouped nuclei. Also with lactic acid you may find the long bacillus, with HCl sarcinæ, and hardly ever the reverse.

It is important to bear in mind that the long bacillus is not diagnostic of malignant disease, but merely signifies food stagnation with absence of hydrochloric acid and presence of lactic acid. Recent work appears to point to the fact that the long bacillus is only suggestive of malignant disease when accompanied by a considerable amount of lactic acid. The reason is that whilst with ordinary albumins these bacilli form little acid, they find in the cancer albumins thrown off as the result of ulceration a medium which enables them to do so in large quantities. It is obvious, therefore, that the long bacillus associated with large amounts of lactic acid will point to malignant disease which has ulcerated. The long bacilli, which, according to Heineman and Hefferan, are identical with the Bulgarian bacillus, when present in large numbers frequently pass into the intestines and may be recovered from the stools by the same technique.[1]

Macroscopic food residues show us that the stomach is unable to empty itself during the night and signify some obstruction in the pylorus or duodenum. The association of lactic acid points to its probably being of a malignant nature.

If the food residues are microscopic it is probable that we have a cancer infiltrating a small portion of the wall of the stomach. The immediate effect of this is a local loss of motility, which will increase *pari passu* with the extension of the affected area. At last a stage will be reached when the movements of that part of the stomach wall are not sufficient to dislodge the mucus with which it is covered, and food particles will lodge in the rugæ and on the surface.

C.—Digestion in the Stomach.

We should in all cases ascertain to the best of our ability the degree of gastric digestion, as even in affections apparently confined to the intestines the trouble may have a gastric origin. Indirectly we may infer an abnormality of gastric digestion when we find connective tissue remains in the stools, but the most satisfactory way of finding out what we require is by the direct examination of the stomach contents after a test meal.

The points which should receive our attention are:—

1. *The presence of an abnormal amount of mucus.*—This is a certain indication of chronic gastritis.

2. *The HCl content of the gastric juice.*—(*a*) If normal there may be respectively a normal stomach, simple atony of the stomach of insufficient severity to lead to retention of food residues, pyloric stenosis not sufficient to delay materially the emptying of the stomach, or a pure neurosis. (*b*) Increase of HCl acidity. We may have nervous hyperchlorhydria, acid gastritis, a gastric or duodenal ulcer, a gall-stone, or a latent appendicitis. (*c*) Diminution of HCl. This may result from a general condition, such as neurasthenia or anæmia, from a chronic gastritis, or from malignant disease of the stomach. (*d*) Absence of HCl. This is always a most important symptom. Rarely a neurosis, it practically always denotes either the terminal stage of a chronic gastritis or atrophy of the secreting glands either of benign or malignant origin.

3. *Digestion of starch.*—As a general rule the extent to which starch digestion is carried out in the stomach may be taken as a confirmation of our findings as to the amount of free HCl, being in inverse ratio to it. The chief practical use of ascertaining whether starch is digested in the stomach is to guide us in the selection of a suitable diet.

4. *The secretion of the gastric ferments.*—The estimation of the pepsin and rennin has at present very little value for diagnostic purposes, as they usually follow pretty closely the amount of HCl secretion.

A rough estimation as to the efficiency generally of proteid digestion in the stomach may be made without passing a stomach tube by a simple examination of the stools. It appears that collagen, the basis of connective tissue, is not acted upon by the pancreatic juice unless it had been previously cooked or exposed to the action of HCl. It follows therefore that if we administer to a patient connective tissue which is practically uncooked and find it reappear in the stools, we may be certain that there must be a defect in the

[1] See author's work, Soured Milk and Pure Cultures of Lactic Acid Bacilli in the Treatment of Disease. London. 1910.

amount of HCl secretion in the stomach. That is, of course, that we take care to give only such an amount as should in the ordinary way be efficiently dealt with by a healthy stomach. This is approximately the amount contained in 100 grammes of beef. If the beef is passed through a mincing machine, made into a cake and fried lightly on both sides in butter, so that the middle is still quite pink in colour, the connective tissue will be raw enough for our purpose.

D.—Evidence of Functional Hepatic Insufficiency and of Disease of the Biliary Ducts.

It is probable that a pathological excess of urobilin in the urine always means either: (*a*) functional hepatic insufficiency; (*b*) some obstruction to the free flow of bile into the intestine; or (*c*) auto-hæmolysis.

The chief clinical sign of hepatic insufficiency is diminution in the amount of urea excreted in the urine, in conjunction with increase in ammonia, uric acid, and purin bodies, and the presence in severe cases of leucin and tyrosin. But in order that the amount of urea may have any diagnostic significance it is necessary to make sure that it is not due simply to deficient ingestion of nitrogen-containing food. This could, of course, be done by estimating the nitrogen content of the diet of the patient, but in practice we secure the same results by the far simpler method of taking into account not the absolute amount of urea excreted in a day, but the relation between it and the total amount of urinary nitrogen. "Any lowering of the ratio of urea to urinary nitrogen below 83 per cent. is a sign of hepatic insufficiency."[2]

Interference with the free passage of bile into the intestine, such as is met with in chronic disease of the bile ducts or in gall-stone disease, is characterised by: (*a*) the same defective utilisation of fats as is met with in deficient secretion of the pancreas but to a lesser degree; (*b*) deficiency in the colouring matter in the fæces; and (*c*) the presence in the urine of urobilin and bile pigment.

The presence of traces of bile in the urine is of greater diagnostic importance than is commonly supposed. Harry Adler[3] has noted the fact that in many cases of obscure abdominal pain, in which gall-stones and chronic cholangitis were subsequently demonstrated by operation, he was struck by the fact that almost invariably traces of bile could be demonstrated in the urine by Rosin's test. (A green ring formed at the junction of the urine and a weak alcoholic solution of iodine.)

Cammidge and Robson[4] state that bile pigment could be detected in the urine in 62 per cent. of cases of chronic pancreatitis associated with cholelithiasis and in only 16 per cent. of those in which no biliary calculi could be found in the common duct at the time of operation. Pathological excess of urobilin also appears, according to these observers, to denote some degree of obstruction to the free passage of bile into the intestine. The combination of both bile pigment and urobilin renders the existence of some degree of obstruction in the common duct practically certain.

One can distinguish between hæmatogenous and hepatogenous urobilinuria by the fact that in fresh urine urobilin is present, not as such but as a urobiligen, which oxidises into urobilin under the influence of light. In urobilin derived from hæmolysis the reaction will be obtained very soon after the urine has been passed, whilst in that resulting from the interference with the passage of bile into the intestine not until one or two days afterwards. We shall have, of course, in the former some degree of anæmia.

E.—Defect in the Pancreatic Secretion.

This can be ascertained from the examination of the stools after a test meal by finding:—

1. *Undigested muscle fibre.*—100 grammes of meat taken during the day by a healthy person should be entirely digested and absorbed, and no remnants, either macroscopic or microscopic, should be discoverable in the stools in an undigested condition. From numerous experiments it has been proved that muscle fibre is never completely digested in the stomach. The appearance of muscular fibres which have not lost their striation in the stools must point conclusively to defect in the proteid digestion in the intestine, and necessarily implies that the pancreatic secretion is deficient.

2. *Alteration in the utilisation of fat.*—(*a*) Excess of saponified over unsaponified fat in the fæces may point to increased activity of the pancreatic secretion, and is frequently met with in hyperchlorhydria as the direct result of the excess of free HCl, the natural activator of the pancreas. Such an excess of pancreatic secretion is, I am sure, exceedingly common as the pancreatic catarrh which forms the first stage of chronic pancreatitis. Excess of saponified fat may also be due to the action of bacteria, and points to abnormal putrefactive processes in the upper part of the intestine. When this is the case there will be invariably other evidences of putrefactive processes in the intestine, such as indicanuria, and the usual syndrome of auto-intoxication. There will also naturally be evidence of defective pancreatic secretion, such as the presence of undigested muscular fibre and the positive result of the tryptic insufficiency test, and we shall, under these circumstances, be justified in assuming that the excess of saponified fat means intestinal catarrh.

(*b*) Diminution of saponified fats. This will point to some degenerative change of the pancreas, is often met with in the later chronic stage of intestinal indigestion, and in conjunction with the pancreatic C reaction will suggest cirrhotic changes in the pancreas due to long-standing chronic inflammation.

(*c*) Excess of unabsorbed fat. This will show that there is some interference with the functions of the pancreas, provided that we can exclude defective gastric digestion, biliary obstruction, and an excess of fats in the food, especially those, such as mutton fat, having a high melting point.

3. *Tryptic insufficiency test.*—Of all the methods which have been devised for measuring the functional activity of the pancreas, the most certain and direct is that which consists of determining the presence of trypsin in the fæces. It is a well-known fact that a certain proportion of the trypsin of the pancreatic juice is not used up in the duodenum, and may be found in the stools. Nature is not parsimonious, and habitually supplies an excess of digestive fluids over the amount actually required. It follows, therefore, that if we can demonstrate the presence of trypsin in the fæces there must be enough and to spare of pancreatic juice secreted, and there can be nothing very wrong with the pancreas in the direction of functional failure. If we find a relative excess of trypsin in the fæces we have strongly suggested a condition of catarrhal hypersecretion of the pancreas, such as is met with in the first stage of chronic pancreatitis. If, on the other hand, we find diminution or absence of the tryptic ferment in the stools, we may assume that there is some affection of that organ which materially interferes with its secretion.

The best method at present at our disposal for estimating the amount of trypsin present in the stools appears to be that devised by Gross,[5] which is based upon the time taken by an aqueous extract of a given quantity of fæces to digest a standard weight of casein. To secure the best results it is important that the patient should be at the time upon a diet consisting mainly of proteids, this having been shown to produce the largest output of trypsin in a healthy person. Normally, 10 cubic centimetres of a 1 in 3 suspension of fæces should digest three-quarters of a grain of casein in from 12 to 14 hours. In abnormal conditions the time may be much reduced or extended. One ascertains the moment when all the casein is digested by failure to obtain a precipitate with acetic acid.

F.—Evidence of Chronic Pancreatitis.

It is now quite certain that chronic pancreatitis is a much commoner affection than has hitherto been imagined, and that it explains the pathology of a certain proportion of obscure gastro-intestinal disturbances. In many cases of chronic pancreatitis, especially when resulting from infective extension from a duodenal catarrh, there may be no pain or jaundice, but merely a dyspepsia of the atonic type with flatulence as a prominent symptom. It is consequently necessary to definitely exclude pancreatitis before assuming the presence of an uncomplicated gastric catarrh, it being morally certain that many cases of so-called gastric catarrh remain uncured by treatment because they are in reality chronic pancreatitis.

[2] Combe: L'Autointoxication, p. 283.

[4] The Pancreas: Its Surgery and Pathology. London. 1907.
[5] Deutsche Medicinische Wochenschrift, p. 796, vol. xxxvi.

Again, as I have pointed out elsewhere,[6] the presence of chronic pancreatitis probably has considerable diagnostic value in the recognition of duodenal ulcer, as if gall-stones can be excluded a local source of irritation in the duodenum is suggested. This, in the presence of rigidity of the recti muscles, hunger pain, or abdominal tenderness, may give the casting vote against a hyperchlorhydria of functional origin.

For the recognition of chronic pancreatitis we rely mainly upon the Cammidge C reaction[7] in conjunction with the other signs of abnormality in the pancreatic juice already mentioned. According to Cammidge and Robson, the presence of crystals of oxalate of calcium in the urine are strongly confirmatory of chronic pancreatitis, having been found in 73 per cent. of all cases examined. They do not appear to occur in acute pancreatitis, and very rarely in malignant disease of that organ.

G.—Signs of Abnormal Putrefactive Processes in the Intestine.

We cannot prescribe intelligently for any case of neurasthenia, intestinal dyspepsia, or diarrhœa unless we know whether or not there are abnormal putrefactive processes in the intestine.

The signs upon which we found our opinion are *urinary* (excess of indican, excess of conjugate sulphates, and the presence of phenols and their congeners) and *fæcal* (the excess of Gram-positive over Gram-negative forms in stained cover-glass preparations, alkalinity of reaction, excess of anaerobic bacteria, and abnormal fermentation in Strasburger's tubes).

H.—Signs of Intestinal Catarrh.

The diagnosis of intestinal catarrh is made chiefly from the demonstration of mucus and an increased amount of inorganic ash in the fæces.

Mucus in the fæces must always be considered as pathological, and to denote either a functional disturbance of secretion or more frequently an anatomical disease. We are enabled to deduce from the appearance of the mucus and the way in which it is mixed with the fæcal matter the part of the intestine from which it comes. Pure mucus without any admixture of fæces denotes catarrh of the rectus, sigmoid, or lowest part of the descending colon. Fæcal masses covered exteriorly by a thin layer of mucus point to constipation, fæcal retention, and irritation, and consequent catarrh of the lower bowel. Mucus, whether macroscopic or microscopic, if intimately mixed with fæces, suggests catarrh of the upper colon or of the small intestine. If the flakes of mucus are either bile-stained or become green when acted upon by a strong aqueous solution of corrosive sublimate, it may be considered practically certain that they come from the small intestine.

The amount of inorganic ash in the fæces varies normally between 10 and 15 per cent. It is increased in catarrhal inflammation of the intestine, and this increase is greater the nearer the lesion is to the anus. A large or considerable excess of inorganic ash renders the diagnosis of chronic colitis practically certain and is a valuable confirmation of other signs.

I.—Evidence of Bleeding into Any Part of the Gastro-intestinal Canal.

One of the most marked features of the last two or three years has been the improvement in the technique for detecting minute amounts of blood in the fæces (occult blood), and our tests are now quite delicate enough for all practical purposes. As regards the significance of the finding, observers are mostly agreed that a negative result of the test is much more valuable from a diagnostic point of view than a positive one. For instance, in the absence of hydrochloric acid in the stomach contents with no retention of food, the continued absence of occult blood in the stools would go far to negative the suggestion of a gastric carcinoma.

The information to be obtained from the presence of occult blood in the stools, the patient being on a hæmoglobin-free diet, may be briefly stated as follows:—1. The constant presence of occult blood strongly suggests malignant disease of the stomach or intestines. 2. Intermittent presence suggests a gastric or duodenal ulcer. 3. Appearance of occult blood in the stools of a patient who has been apparently cured of an ulcer of the stomach or duodenum strongly points to an impending relapse. As Boas has wisely suggested, all cases of cured ulcer should have periodical examinations of the stools for occult blood for some months until the continued absence of blood shows complete healing. 4. The test for occult blood is of extreme value to us during the medicinal treatment of stomach or duodenum, to tell us when it is safe to make any improvement of the diet. Should occult blood appear at any time after an increase of food has been given the patient it will show that the change has been prematurely made and we must try back for a little.

In any case the appearance of occult blood in the stools points out that there is some bleeding going on in the gastro-intestinal tract, and indicates the absolute necessity for a thorough examination and investigation of the patient.

I hope that by this time it is quite plain, first of all, that a real diagnosis of a case of disturbance of the stomach or intestines can only be made by a study extending over several days, and that an opinion arrived at in any other manner must be a pure guess, possibly correct, but still only a guess. Secondly, that there is no need to despair if, after having asked his patient the usual questions and palpated the abdomen, one is not able to say definitely anything more than that the patient has "indigestion." I hope that I have succeeded in showing that there are still methods to be tried before the physician is justified in treating the case by the method of trial and error or sending it to the surgeon. It only remains to consider the best method of putting the patient through the different tests.

The first difficulty is usually with the patient himself. He would be perfectly satisfied with a diagnosis such as "acid dyspepsia," and it is difficult to make him understand that it is not a diagnosis at all, but simply a statement in other words of what he knows already. And he naturally cannot understand why, if a diagnosis of a disease of heart or lungs can be made at once in the consulting-room, those of the digestive system should require further investigation and be in a different category. His natural tendency is to lose confidence and to go to someone else who will diagnose "acid dyspepsia" or "constipation" or something similarly meaningless, and not put him to the trouble or expense of further investigation.

But assuming that the patient really wishes to get well and is willing to take some trouble to do so, how shall the tests best be carried out?

The very first thing is to decide which tests are necessary in the particular case under investigation, as it may not be necessary to go through the formidable list which I have enumerated. In many cases there may be just one or two things which we require to ascertain to clench the diagnosis; and it frequently happens that it is not necessary to pass a tube into the stomach of the patient, as we may obtain all the additional data which we must have from the examination of the stools and urine. In any case it is as well to commence the investigation by a thorough analysis of these, as we cannot fail to acquire an immense amount of definite information as to the condition of the gastric and duodenal digestions, the condition of the pancreas, and the presence or absence of intestinal catarrh, information which will safely guide us as to the extent and nature of the further investigations required for the elucidation of the case.

The next point is to make arrangements for obtaining the facilities necessary for the efficient performance of the tests. Even in a case in which the investigation is limited to the examination of the stools and urine we shall require: (*a*) the collection and measurement of the 24 hours urine; (*b*) the daily collection of the fæces, and opportunities of inspecting and microscopically examining them in a fresh condition, separating the carmine-coloured portions; (*c*) a period during which the patient is upon a test diet containing measured amounts of meat, bread, milk, potatoes, &c.; and (*d*) a second period during which all hæmoglobin is excluded from the patient's diet in order that the stools may be examined for occult blood.

To attempt such an investigation in the patient's home is almost impossible; it would necessitate a very large amount of detailed instruction on the part of the medical man, as the work would have to be carried out either by the untrained

[6] The Diagnosis of Duodenal Ulcer, with Special Reference to the Pancreatic Reaction, Clinical Journal, Jan. 12th, 1910.
[7] The Pancreas, its Surgery and Pathology, by Mayo Robson and Cammidge, London, 1907, p. 252.

friends of the patient or by hired nurses who would be probably equally unversed in the minutiæ of the diets and methods. The preparation of the test diets not only requires scales and weights, but necessitates an alteration in the usual household arrangements, and throws a certain amount of extra work upon often unwilling domestics. Besides, the medical attendant will have to pay visits at unusual and inconvenient hours, such as before breakfast. The collection of stools and urine is not by any means a task which will be undertaken with alacrity by ordinary servants.

Taking all these facts into consideration, it is far better for the patient to enter a nursing home for a week, into which space of time the necessary tests can usually be compressed. Here the preparation of the different test meals, the administration of the enemas, the collection and preservation of the stools, are part of the daily routine and are carried out as a matter of course, and the medical man can visit early or late without upsetting or inconveniencing anybody.

Harley-street, W.

MATERNITY CASES IN THE LIVERPOOL WORKHOUSE HOSPITAL DURING 1907, 1908, AND 1909.

BY WILLIAM ALEXANDER, M.D. R.U.I., F.R.C.S. ENG.,
VISITING SURGEON TO THE INSTITUTION.

IN THE LANCET of April 6th, 1907, p. 940, there is a report upon the maternity wards of the Liverpool Workhouse Hospital for 1906. The present communication is a similar report for the years 1907, 1908, and 1909.

Total number of women admitted, 1330; married, 761; single, 569; primiparæ, 455. Residing in the workhouse for variable times before confinement, 382; admitted direct from town when in labour, 926; admitted from the workhouse lock ward, 22.

Of *maternal mortality* there were six cases, details of each of which are here given in condensed form.

1. *Case 163, 1909.*—Aged 40; 12-para; admitted in labour suffering from vomiting and albuminuria. Confinement natural. Baby premature and stillborn. Vomiting persistent after labour. Suppression of urine set in gradually and continued until death, six days after. Post-mortem examination: Kidneys much congested and large, pelvis normal, increase of fluid in pericardium, and general œdema.
2. *Case 350, 1909.*—Age 36; 5-para. Normal labour Sept. 15th. Albumin in urine. Chest tubercular. Patient sent to the medical wards, where she died from uncomplicated phthisis on Oct. 9th. No post-mortem examination allowed.
3. *Case 90, 1908.*—Age 29; 4-para. Admitted with a temperature of 101·8° F. Pleuro-pneumonia diagnosed. Double pneumonia supervened and the patient died seven days after from that disease. A post-mortem examination verified the diagnosis. Pelvis healthy.
4. *Case 172, 1907.*—Age 21. Patient admitted from the medical wards in a state of collapse, with constant vomiting for three days previous to admission. She did not rally, but died next day from syncope and signs of œdema of the lungs. No post-mortem examination.
5. *Case 289, 1907.*—Age 26. Patient admitted in labour. Had had no food for ten days before admission. Powerless labour, forceps applied. Died from sepsis. Abscess found in broad ligaments, pus in uterus, probably previous pyosalpinx.
6. *Case 294, 1907.*—Age 22. Labour quite normal. Seven hours afterwards eclampsia set in and patient died in 28 hours, no remedies having the slightest effect on the course of the disease. A necropsy showed œdema of the lungs and cerebral congestion.

The above are all the deaths from every cause of every woman who was admitted to the maternity wards during these years, and include all who have died from any cause during the month following their confinement. The statement in the *Hospital* of Jan. 15th, 1910, p. 466, that we only count deaths from purely maternity causes is absolutely false, and we shall be only too glad to show our books to anyone interested in the truth of the matter.

Infantile mortality.—Mature, dying soon after birth, 22; mature, stillborn, 15; premature and immature, 78; premature and decomposed, 82. Of the mature the causes of death were debility, cyanosis, syphilis, and apnœa, but in most of the cases debility was the cause. Of the mothers admitted during 1909 19 had suffered, or were suffering, from syphilis. In 6 cases syphilis was suspected, but the grounds for suspicion were not conclusive. In the other years the proportion of syphilitic children has not been made out, but is probably much the same.

Children born.—Males, 704; females, 653; twins, 27.

Presentations.—Head, 1272; transverse, 11; breech, 46; knee, 1; foot, 23; face, 4; shoulder, 1; with cord, 17.

Operations.—Forceps, 57; versions (podalic), 14.

Complications.—Eclampsia, 3; albuminuria, 32; pneumonia, 4; hæmorrhage, 45 (accidental 26, unavoidable 15, post-partum 4); adherent placenta, 4; adherent membranes, 5; retained placenta, 1; ophthalmia in infants, 13 (neonatorum 4, catarrhal 9).

Number of mothers removed from the maternity wards on account of temperature, 5.

Number of midwives trained during the three years, 61. Of these 37 entered for the Central Midwives Board examination, two of whom failed. 25 nurses also had each a month's training in monthly nursing.

Remarks.

The maternal mortality is 0·45 per cent., a fractional quantity of which we are very proud considering the class of mothers we have to deal with, as indicated by the large number of immature babies who survived birth by only a few hours, and the still larger number of dead and decomposed infants that are to be found in the statistics. This lying-in hospital has been in constant use, and our records date back to 1858, more than half a century ago. It has been celebrated all that time for its remarkably low maternal mortality. In her notes on lying-in institutions published in 1871 Miss Nightingale refers in some detail to the statistics of the Liverpool Workhouse Maternity supplied to her by my predecessor, Mr. Barnes, and she gives in a table the admissions and the maternal mortality for the five years 1866, 1867, 1868, 1869, and 1870. The admissions were 2466, and the maternal mortality 13, or 0·53 per cent., a very much more remarkably low mortality at that period than is the 0·45 per cent. mortality for the past three years. The term asepsis was then unknown, and the architectural arrangements were the same except that the lavatories were more awkwardly situated than they are now. Yet the results were the envy of maternity hospitals throughout the country, and many deputations visited us to ascertain the conditions that brought us such safety. Many suggestions were made by these visitors as to the supposed cause; most were, however, unwilling to recognise that our charter of safety lay in our straw beds, beds that were discarded as soon as used and of which each patient used three, one in the delivery ward, one in the lying-in ward, and a third in the recovery ward, as described in THE LANCET in the article dealing with the same wards for 1906. They went away in sorrow because they had large possessions of valuable mattresses (hair), feather pillows, &c., and they could not stoop so low as to adopt straw beds. Fortunately for them, antiseptics and asepsis have allowed full scope for both safety and expense, and our workhouse maternity has now lost its pre-eminence in safety, but maintains its equality in that direction, while its pre-eminence in economy is much more marked than it ever was before. We have given up the straw beds owing to the introduction of fibre, which makes a cheap, easily replaced, and a more comfortable bed, and flock pillows have been substituted for straw ones.

Much the same routine is followed as was described in THE LANCET, but each patient now has only two beds during her passage through the lying-in, the delivery bed being removed from the maternity ward when the mother passes into the recovery ward. Here she obtains a new bed which has never been occupied by any person before, and this she uses until she leaves the maternity division. The bed is then sent away, never to return. The delivery bed is likely to become soiled with discharges, &c., and hence it is only used during delivery. From the behaviour of the patients it may be concluded that the fibre beds are very comfortable; the sleep is sound, and no complaints have ever been made about their hardness.

In the *Hospital* of Jan. 1st, 1910, p. 395, Sir Henry Burdett says: "We may point out although classification is essential for moral reasons in the general wards of a Poor-law infirmary, in the maternity wards it is doubly necessary on moral and hygienic grounds. No board of guardians has the right to subject any inmate of a Poor-law infirmary in any department to the risks of contracting a loathsome contagious disease, much less to permit infants to be subjected to such risks." In another place he says: "There they will see girls of 16 and young women who are physically healthy crowded together in the same wards with older women who may be suffering from contagious diseases of the most repulsive kind."

Now this picture is calculated to stir up the emotions of tender-hearted men and women, but it is drawn from the

imagination and not from real facts. The true picture is this: Women of child-bearing age come to the lying-in wards of the workhouse *at all hours of the day and night in labour*, and are received by the midwife in charge. Febrile cases and cases delivered in transit, as occasionally happens, are not admitted, as constituting a danger to the other inmates of the maternity, but all others in labour are. They are admitted without question, cleansed and prepared according as their condition allows, but any moral inquisition to decide the moral innocence or guilt of the applicants at that time would be out of the question. Some of Sir Henry Burdett's "girls of 16" are the most degraded and debauched of our applicants. These women are, it should be remembered, mostly strangers to us and come in from a big city in a condition of labour, and our primary duty is to attend to their great need, which is all the classification that can be made.

Now there is not the slightest risk of any woman or child being infected by a loathsome disease from any other inmate. The medical men and nurses in attendance may be in danger, but using the precautions we do we have never had a case of blood-poisoning contracted in the one case or the other in the lying-in wards in the writer's time. The patients are never "crowded together." Each nurse, who is already trained in medicine and surgery, attends to only one case at the time, and is on the *qui vive* for her own sake as well as for the sake of the other patients for any signs of contagious disease. No woman ever sleeps on a bed that any other woman has ever slept on, and each baby has its own cot made up anew for itself, its own towels, bottles, &c.

After delivery the moral and physical conditions of the women declare themselves. The syphilitic are sent to the lock wards, the innocent girl is advised to communicate with her relations and friends, and as soon as she is well often goes home. But all while passing through the maternity wards have to conduct themselves in a becoming manner and are under the constant supervision of the nurses, and it might be astonishing to find them so quiet and subdued as they really are did we not remember that such quietness and seriousness are only natural after having passed through such a crisis in their lives.

Agnes Jones laboured in these very lying-in wards, and her life and work have stimulated the nursing staff ever since to higher aspirations. We all know that the Liverpool Workhouse is old and obsolete, but the advancements in medicine and surgery, combined with the indomitable energy of the lady superintendent and her staff, have overcome the architectural defects, and we can only say that the hospital, though old and defective, is still *efficient*. Changes are bound to come, and the marble and silver of other palatial hospitals will perhaps in time adorn a new Liverpool Workhouse Hospital, but whether the results will be better will depend, not on the lavish expenditure of money on display, but on the devotion and skill of the medical and nursing staff.

THE ACTION OF LIQUID KOLYNOS UPON THE BACILLUS OF INFLUENZA.

BY JOHN C. THRESH, M.D. VICT., &C.,
LECTURER ON PUBLIC HEALTH, LONDON HOSPITAL MEDICAL COLLEGE;
AND
J. F. BEALE, B.A. CAMB., M.R.C.S. ENG., D.P.H. OXF.,
DEMONSTRATOR OF PUBLIC HEALTH, LONDON HOSPITAL MEDICAL COLLEGE.

THE kolynos preparations have recently been referred to in the Analytical Records from THE LANCET Laboratory.[1] They are described as "what pharmacists call elegant preparations" and as containing the following antiseptic agents: "benzoic acid, eucalyptus oil, peppermint oil, and thymol." The liquid preparation is certainly a very pleasant one for maintaining oral sepsis assuming that the claims made for it can be substantiated. Experiments made by Professor Loeffler have shown that kolynos is capable of destroying in a short time diphtheria bacilli, streptococci, and pneumococci, not only *in vitro* but in the human mouth. We have extended these investigations and ascertained its effect upon the influenza bacillus.

The bacillus used was obtained from Kral's laboratory, Prague, and subcultures were made on blood-agar every fourth day whilst the experiments continued. These experiments were made to determine the action of various dilutions of kolynos upon the bacillus: (*a*) in a broth emulsion; (*b*) in the presence of saliva; and (*c*) in the presence of such organic matter as may be brushed from the teeth.

The process adopted was as follows. The surface of a 48-hour blood-agar culture of the bacillus was scraped by means of a platinum loop, and the bacteria removed were thoroughly emulsified in 5 cubic centimetres of sterile bouillon, or in saliva, or in the teeth washings. Dilutions of kolynos with distilled water were prepared, 5 cubic centimetres of each dilution were placed in sterilised test-tubes, and each was inoculated with five drops of the bacillary emulsion. A control solution containing no kolynos was also prepared. At intervals of one minute subcultures were made on large blood-agar slopes, and after incubation at 37° C. for 48 hours any growth obtained was carefully examined, after staining by Gram's method and counter-staining with weak carbol-fuchsin.

TABLE I.—*Action of the Diluted Kolynos on the Influenza Bacillus in Watery Emulsion.*

Dilution.	Time culture exposed to action in minutes—									
	1	2	3	4	5	6	7	8	9	10
Control: No kolynos ...	+	+	+	+	+	+	+	+	+	+
3½ per cent. kolynos ...	+	+	+	+	+	+	+	+	+	+
4 ,, ,, ...	+	+	+	+	−	−	−	−	−	−
6 ,, ,, ...	+	−	−	−	−	−	−	−	−	−
10 ,, ,, ...	−	−	−	−	−	−	−	−	−	−

+ = Growth. − = No growth.

The results show that a 4 per cent. solution kills the influenza bacillus in five minutes, a 6 per cent. solution in less than two minutes, and a 10 per cent. solution in less than one minute.

TABLE II.—*Action of Diluted Kolynos on the Influenza Bacillus in Salival Emulsion.*

Dilution.	Time culture exposed to action in minutes—									
	1	2	3	4	5	6	7	8	9	10
Control: No kolynos ...	+	+	+	+	+	+	+	+	+	+
4 per cent. kolynos ...	+	+	+	+	+	+	−	−	−	−
5 ,, ,, ...	+	+	+	−	−	−	−	−	−	−
6 ,, ,, ...	+	−	−	−	−	−	−	−	−	−

Admixed with saliva the kolynos kills the influenza bacillus within seven minutes in a 4 per cent. solution; within four minutes in a 5 per cent. solution; and within two minutes in a 6 per cent. solution. The presence of saliva therefore interfered little if at all with the action of the kolynos. The whole of the other bacteria present in the saliva were not destroyed, but they were considerably reduced in number in the solutions containing 5 and 6 per cent. of kolynos.

TABLE III.—*Action of Kolynos upon the Influenza Bacillus in the Presence of Teeth-washings.*

Dilution.	Time culture exposed to action in minutes—									
	1	2	3	4	5	6	7	8	9	10
Control: No kolynos ...	+	+	+	+	+	+	+	+	+	+
4 per cent. kolynos ...	+	+	+	+	+	+	+	+	−	−
5 ,, ,, ...	+	+	+	+	+	+	−	−	−	−
10 ,, ,, ...	−	−	−	−	−	−	−	−	−	−

The 5 per cent. solution of kolynos therefore destroyed the influenza bacillus in less than seven minutes and the 10 per cent. solution in less than one minute. The strength recommended for use is stated on the labels to be 33 per cent. It is obvious, therefore, that a dilution of this strength

[1] THE LANCET, April 9th, 1910, p. 1007.

will kill the influenza bacillus practically instantaneously, certainly during the time occupied in brushing the teeth and rinsing the mouth.

An attempt was made to ascertain the action upon the influenza bacillus in patients suffering from influenza. There was a difficulty in finding cases in which the bacillus could be detected, but a group of three undoubted cases were selected in which the bacillus influenzæ and micrococcus catarrhalis were found. The cases were all typical influenza of moderately severe type.

CASE 1.—The patient, a male, aged 29 years, when first seen was having a rigor, the temperature being 97·2° F. and the pulse 82. The throat was red and congested, there was frontal headache, and also pains in the back and the limbs. He was ordered to bed and to use kolynos as a dentifrice and spray. Three days later he was much improved; the throat looked normal, but there was a good deal of post-nasal discharge, and a little headache. The spray was continued, and two days later, when seen, the patient was practically well.

CASE 2.—The patient, a male, aged 29 years, when first seen had a temperature of 102° F., and the pulse was 104. Pain in the head and the eyes was severe, and in the back and the limbs it was slight. The urine was highly coloured. The fauces were swollen and red, and the tongue was furred. The bowels had been opened; the patient was sweating. Kolynos was used. Next day the temperature was 99°, the pulse was 80, and the pains were diminishing. He had profusely sweated during the night. Three days later the temperature and the pulse were normal, but there was a little tenderness upon deep pressure over the left frontal sinus. A stronger spray was prescribed, and the use of the kolynos as a dentifrice was discontinued on account of tenderness of gums. The patient was allowed out of bed. Two days later he was quite convalescent.

CASE 3.—The patient, a female, aged 26 years, after feeling seedy for some hours had a rigor, and when she was seen complained of sore-throat, aching of the back and the limbs, supra-orbital headache, and stiffness in the nose. The temperature was 101° F. and the pulse 124. The spray gave much relief. The temperature two days later was 98·6° and the pulse 92. The patient was practically convalescent.

In none of the above cases could the influenza bacillus or micrococcus catarrhalis be discovered in the swabs taken on the third or fourth days. Use of the spray caused for a short time a profuse discharge of mucus from the nose, with corresponding relief afterwards. Apparently the kolynos used as a fine spray destroyed the bacteria usually found in cases of influenza, and as the treatment seemed to afford speedy relief and the remedy proved an acceptable one, it appears to us to be worthy of an extended trial.

THE TREATMENT OF SPASMODIC ASTHMA BY THE HYPODERMIC INJECTION OF ADRENALIN.

BY BRIAN MELLAND, M.Sc. VICT., M.D. LOND.

ASTHMA for the purposes of this paper is defined in the words of C. T. Williams "as a severe paroxysmal dyspnœa recurring at more or less well-marked periods, generally in the night, the dyspnœa being due to spasmodic contraction of the bronchi, produced by a variety of causes." This rules out altogether the non-spasmodic dyspnœa of emphysema and dilated heart, and so-called renal asthma which appears to be a pure dyspnœa due to cardiac failure with or without lung œdema.

What is asthma? All observers agree that to explain the sudden onset, the hyper-resonant percussion note during an attack, the absence of the ordinary inspiratory and expiratory sounds and their replacement by musical murmurs all over the lungs, a sudden circumscribed narrowing of the bronchial tubes, chiefly the smaller one, must take place.

How are the tubes narrowed? The most usual view is that they are narrowed by the spasmodic contraction of the circular muscle fibres round them. These non-striped circularly arranged fibres were discovered by Reisseissen, and Laennec [1] quotes in support of this view of the disease the fact that during an attack a patient could sometimes after holding his breath so as almost to cause insensibility actually breathe naturally for one or two respirations, thus clearly demonstrating that the spasm was capable of momentary relaxation. Hyde Salter [2] was one of the chief early exponents of this view in England. He points out that the class of remedies which were found effective in relieving the spasm of asthma were those which were found effective in relieving muscular spasm elsewhere, such as emetics, tobacco, &c.

There is, however, another view, supported by Traube, Blackley, and Sir Andrew Clark,[3] that the narrowing of the tubes in asthma is due to a rapid tumefaction of the mucous membrane of the bronchi, a sudden state of congestion or erectility sufficient to cause a diminution in calibre of the smaller tubes. Traube calls asthma a very acute catarrh. Blackley says the asthma of hay fever is the same as the nasal turgescence but extending further to the mucous membrane of the bronchial tubes. Sir Andrew Clark considered the phenomena of an attack to be explained by a vaso-motor neurosis of the mucous membrane by which swelling of it took place suddenly, just as a vaso-motor neurosis of the vessels of the skin may produce urticaria. Storch is said to have actually observed with the laryngoscope during an attack that the whole length of the trachea and part of the right bronchus were deeply congested.

However, whether there is increased tumefaction of the mucous membrane or not, it is probable that the chief element in the narrowing of the tubes is contraction of the circular muscular fibres.

The inspiration is forcible in asthma and causes slight indrawing of the epigastrium and lower ribs, but expiration takes about three or four times as long, and in Bamberger's words, "presents the picture of a most laborious, tormenting, and at the same time fruitless struggle."[4] If the attacks occur frequently these violent expiratory efforts lead to serious damage to the lungs in the production of dilated air cells or emphysema. Exactly why the expiration through narrowed tubes is more impeded than the inspiration is not quite clear.

The type of dyspnœa in asthma contrasts with that seen in spasm or other narrowing of the glottis, or the dyspnœa of plastic bronchitis where the difficulty is inspiratory. Here there is much more indrawing of the epigastrium, intercostal spaces, and supraclavicular regions, and the tendency is towards the production of atelectasis or collapse of the air cells.

Perhaps one of the most instructive ways of looking at asthma is to consider it an exaggeration of a normal defensive reflex in a person with a hypersensitive nervous system. The circular muscles of the bronchi are present in all of us, no doubt for some good reason. If a thoroughly normal individual suddenly finds himself in an atmosphere of sulphur dioxide he will probably get some spasm of his bronchial tubes as well as spasm of his glottis. This is good for him. It prevents too much of the gas getting into the lung alveoli and warns him that something is wrong with the atmosphere.

The chief defensive mechanisms which the lungs have against impurities in the atmosphere are:—1. At the nose: erectility or vascular turgescence of the Schneiderian membrane, which may cause (*a*) the motor reflex act of sneezing, a sudden violent expiratory effort with the glottis momentarily closed, or (*b*) nasal asthma. 2. At the glottis: (*a*) spasm, which may be complete and prolonged, or (*b*) cough, a momentary closure of the glottis followed by a sudden spasmodic expiration. 3. In the bronchial tubes: (*a*) secretion of mucus and ciliary action which carries it upwards till it produces cough; (*b*) spasm of the circular muscles producing asthma.

The vagus is both the sensory nerve to the bronchial mucous membrane and the motor nerve to the circular muscle fibres of the tubes. When the sensory nerve endings are irritated in certain ways the circular muscle fibres contract by a simple reflex; similar to the corneal reflex, for example. The reflex arc probably takes place in all cases through the medulla, though C. T. Williams supposes it may take place through the ganglia in the pulmonary plexuses.[1]

It has been shown by Dresser [5] that electric stimulation of the main vagus produces contraction of the bronchial tubes, and that the motor effect is paralysed by atropine, the tubes failing to contract if the animal is previously injected with this poison.

In addition to afferent impulses from the bronchial tubes themselves, impulses causing an attack of asthma may reach the medulla from the nose, as in nasal asthma (through the first, or more usually the fifth nerve), from the larynx possibly, and certainly from the abdominal organs (stomach and small intestine) supplied by the vagus, as when indigestion excites it. Afferent impulses may come also from the ear, possibly through Arnold's nerve, a branch of the vagus to the external meatus. Thus asthma is sometimes brought on by the irritation of wax in the external meatus and relieved on its removal. Emotion may start a spasm, and in this case the impulse comes through to the medulla from the higher centres.

As contrasted with the normal individual we must suppose in the asthmatic a hypersensitiveness of the nervous system in some part of the reflex arc; in idiopathic asthma an individual sensitiveness to certain stimuli which would not act as irritants at all in a normal individual. We can understand that various sorts of dust, such as road dust, dust from the higher atmosphere as seen in subtropical dust-storms, the dust of cotton-mills, hay-lofts, and flour-mills would produce asthma. When the smell of ipecacuanha, or the pollen of many grasses and flowers as in hay fever, or even the neighbourhood of dogs, cats, horses, or hares produces it, we are more surprised and call it idiopathic.

Some asthmatics attribute their attacks to climatic causes, such as damp air, either hot or cold; others to stuffy air when there are stillness and absence of all wind. I used to find the coast line in the Canary Islands particularly bad for asthma when I was resident there, though large numbers of asthmatics used to be sent out from England by their physicians for the sake of the dry climate. I believe it was due to the irritation produced by fine particles of salt in the air formed by the break of the waves.

The relatively impure atmosphere of large towns in England is usually good for asthma; part of the good may be due to the dryness of the subsoil in these large paved areas. Mist or fog will often cause asthma in the bronchitic, but, curiously enough, some asthmatics never feel better than when in a real London pea-soupy fog. Every asthmatic is a law unto himself as to the influence of climate and locality.

Nasal asthma, or asthma nasal in origin, may be caused by some actual nasal lesion, such as hypertrophic rhinitis, hypertrophied turbinals, polypus, adenoids, or deviation of the septum. When these conditions have been put right by surgery the asthmatic attacks may cease. By far the most common cause of nasal asthma, however, is not a gross lesion in the nose, such as any of the above, but a peculiar irritability of the mucous membrane, an undue sensitiveness which causes, or is associated with, engorgement of the erectile tissue, and which produces a subjective feeling of titillation or tickling. This tickling is sometimes worse in the recumbent posture which favours engorgement. The actual cautery to the turbinals sometimes cures this variety of nose itching and the asthma at the same time, just as it cures the irritable nose of hay fever which often leads on to summer or hay asthma. These irritable noses may produce attacks of severe paroxysmal sneezing instead of, or in addition to, asthmatic attacks, attacks of sneezing so long and so violent that the patient is thoroughly exhausted.

There are various microbic diseases which at certain parts of their course increase the irritability of the vagus, as of many of the other nerves. Syphilis and whooping-cough are cases in point. In whooping-cough and rickets (which is probably due to a toxin) the spasm is mainly laryngeal, and in locomotor ataxy (or late syphilis) we may have "laryngeal crises" as they are called. Syphilitics, however, may develop spasmodic asthma, to which they have been strangers before infection. C. T. Williams[1] suggests that in these cases the bronchial glands are enlarged and press on the vagus in the region of the anterior and posterior pulmonary plexuses, and asthma following on arrested phthisis has been put down by him to the same cause—namely, pressure of enlarged glands (tubercular in this case). According to Fowler,[6] however, the pathological evidence shows that in the asthma of syphilitics there is usually some stenosis of the main bronchi caused by gummatous and fibrotic distortions of the tubes themselves, with dilatation of the bronchus on the peripheric side of the narrowing, and emphysema in the section of lung affected.

Similar distortions with partial stenosis of main bronchi may be produced in the fibrotic contractions of old phthisis, and are more likely to produce asthma than pressure of glands in the mediastinum. Indeed, aneurysm or other tumour in the mediastinum, including tubercular gland masses, seldom lead to asthma, but cause a characteristic spasmodic cough, though they may cause a dyspnœa which differs, however, from true asthma. By far the commonest precursor of asthma is a bronchial mucosa morbidly sensitive to attacks of inflammation in childhood, which may follow the infections of ordinary epidemic catarrh, influenza, measles, or whooping-cough. This asthma associated with bronchitis is said by Hyde Salter to comprise 80 per cent. of all cases.[2] Asthma is hereditary in 40 per cent. of all cases according to the same authority.

C. T. Williams[1] says that the characteristic form of chest is frequently transmitted from parents to children. He is, I think, wrong in this; what is really inherited is the morbidly keen nervous system and morbidly sensitive bronchial mucosa. The barrel shape of the chest is the result of previous attacks of bronchitis or asthma, not the cause of them.

Asthmatics, in addition to possessing a very irritable vagus reflex, are often highly neurotic in other ways and suffer from neuralgia, insomnia, and mental instability. Some asthmatics are liable to outbreaks of nettlerash, psoriasis, or eczema. Various drug habits are easily developed in asthmatics, such as the morphine, alcohol, chloral, hyoscyamine, or cocaine habits. All these drugs are used by different asthmatics to relieve the agony of the attacks, and there is distinct danger of a habit being formed if they are used frequently. We are therefore told by some writers to "renounce the use of specifics." Many of the patients, however, will not renounce them. We are to use instead of these stronger drugs during the agony of the spasm the harmless antispasmodics ether, ammonia, the nitrites, coffee, ipecacuanha, and lobelia. The advantage of these is that if they do not do very much good, at any rate they do not do much harm, and they at least act as a placebo till the spasm passes away naturally.

When I was resident in the Canary Islands I saw many very severe attacks of asthma lasting with slight intermissions for two or three days, and I have several times had to stay all night with patients. I have often had to use all of these harmless antispasmodics one after the other and have been still far from relaxing the spasm. Emetics such as ipecacuanha, in 10 grain doses, apomorphia, or lobelia make the patient feel very bad indeed, and partially relax the spasm, but it usually comes on again after the vomiting is over, and the remedy is nearly as bad as the disease. A little ease has occasionally been obtained with nitroglycerine or amyl nitrite, but it makes some patients feel worse. The true use of the nitrites is in dyspnœa with increased arterial tension, as in certain forms of renal and cardiac dyspnœa, not to relax the spasm of true asthma.

Chloral was more often of some use, but the only drug which relaxed the spasm enough to let the patient sleep as a rule was morphia, ¼ grain or more by hypodermic injection. Some asthmatics arrived with their own syringe and tablets. I found that the temperature previously normal was often raised to 101° or 102° F. after morphia and the patient was left wheezy; the attack did not clear away completely. Of course, if the higher centres and medulla are drugged with any strong sedative the vagus reflex is less acute. One of my patients—an old hand—used to be quite happy if he could retire to bed with a bottle of whisky when he felt asthmatic. Half of it was usually sufficient to relax the spasm. He had renounced the use of other specifics for asthma; he found this the best.

What specific drugs, other than morphia, do asthmatics themselves pin their faith to, and most frequently use during an attack? Fuming inhalations containing datura stramonium or tatula, I believe, are by far the most common. These have been used by physicians for many years, but the popular knowledge of them, Sir James Sawyer[7] points out, dates particularly from about 25 years ago, when they were used by the Earl of Beaconsfield in his last illness, and therefore much noticed in the public press. Such a powder is often represented by some such formula as follows:—potassii nitras, ½ ounce; pulv. anisi fructus, ½ ounce; pulv. stramonii fol., 1 ounce.

The relief is often real and great; the patient can sleep, though the spasm is not quite relaxed. This we can understand when we reflect that stramonium contains the powerful

alkaloids atropine, hyoscyamine, and some hyoscine. As before mentioned, Dresser [5] has shown that atropine paralyses the motor endings of the vagus in the bronchial muscles, so that if the individual can be got well under its influence the spasm must relax. The hyoscyamine and hyoscine act twice as strongly as atropine in paralysing the nerve terminations, and hyoscine also acts on the brain, producing sleep. The smoke of burning stramonium has been shown to contain small quantities of the three alkaloids, so that it is possible for the drugs to enter the blood from fuming inhalations, just as in opium smoking. A spray containing atropine, if finely divided and used early in an attack, is similarly absorbed, and causes relaxation of the spasm by paralysing the bronchial muscles. Any remedy which contains ½ per cent. of atropine requires to be used with great caution.

We now come to what is more particularly the subject of this paper—namely, the treatment of the paroxysm of asthma by the hypodermic injection of adrenalin. In the form of spray adrenalin has been much used in hay fever, and also in hay asthma, but given in this form its effects are not striking. Given by hypodermic injection, however, its effects are truly marvellous in relaxing the spasm of asthma instantly, and as I have seen no notice of this in the medical papers during the last two years I feel sure this action of adrenalin in not generally known. I shall narrate with some detail the first three cases in which I used it; they have all now given it an extended trial and it has never failed.

CASE 1.—A married lady, aged 30 years, came to me in October, 1905, suffering from asthma, which came on every morning at about 3 o'clock. The family history was significant in this, that two of her brothers also suffered from asthma, one so badly as to prevent him from doing much work. The asthma had first started about six years before, while living at the seaside; at first it only came occasionally (every few months), but it had got more and more frequent, till it came nightly. She suffered from hay fever, without asthma, for three summers before the asthma declared itself. The only other previous illness that could be recollected was, that eight years before, she had been swollen all over. She had pain in the back, swollen face and ankles, but the state of the urine and kidneys had not been ascertained till four years later, when albumin was found present in the urine.

The patient was, when I first examined her in October, 1905, a thin, almost emaciated woman, stooping and feeble in her movements. There was dry eczema in the folds of the neck, about the nostrils, and in the bends of the elbows and knees, leading to thickening and cracking of the skin. The chest showed signs of emphysema and slight catarrh; it was somewhat barrel-shaped, slightly over-resonant, and wheezy in expiration. The pulse was always rapid, never under 100, and it rose at once to 120 or 140 when she walked. She got much out of breath when walking, and there were well-marked signs of cardiac overstrain. Albumin was present in the urine, but in very variable quantity—sometimes an appreciable amount, at other times very little. She used a spray of atropine and cocaine. I put her on a mixture of potassium iodide (3 grains), chlorodyne (5 minims), and liquor nitro-glycerini (1 minim) three times a day, with one Nativelle's digitaline granule (¼ milligramme) every other day. There was no very marked alteration under this treatment. Knowing that some people obtained relief in hay fever from spraying the nose with adrenalin solution 1 in 4000, I got her to try it. It eased the attacks a little but not as much as atropine and cocaine.

In January, 1906, she sent for me when a paroxysm of asthma was on. It was not very severe, but was lasting longer than usual. I thought I would try the effect of adrenalin hypodermically, so injected 10 minims of the 1 in 1000 solution into the arm. The effect was instantaneous almost. The pupils suddenly dilated, the eyes widened perceptibly, and the face became more pale, the combined effect of this giving a frightened look to the face. The singing sounds in the chest immediately ceased, and all subjective feelings of tightness passed away. She was at once able to cough quite naturally, and a little expectoration began to come up, as usually happens after an attack has subsided. I never saw such a striking effect from any drug at any time. The absolute completeness and extreme rapidity of the passing away of the asthmatic spasm were the most striking features. Moreover, the asthma remained entirely away for seven days, and before this it had occurred nightly for many months. When the asthma recurred in seven days' time, the adrenalin was used again, and it stopped it just as before. The patient's estimate of the length of time required to stop the asthma completely was "about as long as it takes you to count five." The effect of the adrenalin, however, did not last for seven days on this second occasion, and for a time she was taking away her asthma every night with an injection of 6 minims, which was found quite sufficient. After four or five weeks of this removal of the spasm directly it tried to come on, the incidence of the asthma became much less frequent, and in a period of three months time there were only seven attacks.

She had left off all her old sedative medicines, but still took for a month or two potassium iodide (2½ grains) and liquor arsenicalis (2½ minims) three times a day. The general strength improved enormously, the pulse came down to 80, and the albumin entirely disappeared from the urine.

In this case there has been not only an immediate relief of the spasm whenever adrenalin was used, but the regular breaking of the spasm, whenever it occurred, over a consider able period of time seems to have very much discouraged the nervous system, so that it is far less ready to give way to asthmatic attacks. More lately the patient has had a temporary nervous breakdown, but the asthma keeps away for months at a time and her general health is enormously improved.

CASE 2.—The patient, a married lady, 27 years of age, began with asthma at 12 years of age, after an attack of bronchitis. The asthma has been worse in summer as a rule, in dry hot weather, but she has attacks at all times of the year. There is no doubt that in this case dust acts as an irritant, as the asthma is very liable to come on after motoring. The dust of a hay-loft has brought it on, and it is very liable to come on after a dance in a crowded ballroom. This patient cannot bear hot stuffy rooms, and has been accustomed to take a good deal of exercise in the open air. Fog and mist seem to have no influence in causing an attack. She has used for eight or nine years a stramonium burning powder whenever the attacks have come on. She took the Buffalo cure for 18 months some years ago, but without any appreciable effect. This patient, like many asthmatics, does not look upon herself as an invalid, and usually treats herself, but in 1902 I was sent for in a severe attack which did not yield as usual to the burning powder. I first tried the inhalation of a capsule of nitrite of amyl. This she disliked, as it did not relieve the breathing at all, and made her feel ill. The spasm was finally made a good deal easier with an injection of morphia (¼ grain). Afterwards she took potassium iodide and digitalin for a few weeks, but I saw no more of the case till July, 1906, when I was sent for to relieve an attack, which was again much worse than usual. I injected ¼ grain of morphia as before. This had caused no relief at all within 15 minutes, so that I then injected 8 minims of adrenalin. This caused immediate relaxation of the spasm. She was married a few weeks after this, and had asthma every day while away on the continent in very dry dusty weather. She could always take away the asthma at once with an injection of 4 or 5 minims of adrenalin, but it would return in 12 hours, so that two injections a day were taken for about a month. When she shortly became pregnant the adrenalin was discontinued owing to the fear that it might act as an oxytocic, but it was used two or three times during pregnancy when the spasm was worse than usual and would not yield sufficiently to the burning powder.

This patient improved very much in general physique and gained weight considerably, but this may have been connected with maternity and not with adrenalin. In this case I do not think that the incidence of the attacks has been much altered in frequency, but after the first month the adrenalin has not been used as the regular remedy to cut off the spasm at once. The burning powder is used first, as it is probably less trouble for a person not accustomed to a hypodermic syringe, and adrenalin is only used afterwards when the attack is severe, and will not yield. It stops the attacks as rapidly as when first used two and a half years ago. I believe that the asthma should be checked directly it comes on by injection of adrenalin, if the habit is to be altered and the incidence to be rendered less frequent.

CASE 3.—A lady, aged 34 years, began to suffer from hay fever with asthma in the summer of 1904. There were much stuffiness, bronchitic wheezing, and breathlessness on exertion all day as well as the more marked asthma at night time. The nasal symptoms were relieved considerably by a weak cocaine spray, one or two grains to the ounce of camphor water, which personally I find by far the most useful treatment in simple hay fever. For the asthma she was given a medicine with a formula constructed after that of Dr. Hare's anti-asthmatic elixir, one to two teaspoonfuls three times a day: sodium iodide, 2 grains; sodium bromide, 2 grains; tincture of lobelia, 2 minims; fluid extract of euphorbia pilulifera, 3 minims; nitroglycerine, 1-200th grain; aqua, &c., to 1 drachm. This made little difference to her condition. Her bronchial asthma and hay fever disappeared at once on going a sea voyage.

In 1905 she again suffered in the same way for six or eight weeks during the hay season. In 1906, when the asthma and hay fever returned, I gave her adrenalin (5 minims) by hypodermic injection. It removed the asthma at once. She then began having nightly injections when the asthma came on at about 3 A.M., and finally she hit upon the expedient of taking an injection every night at bedtime so that the spasm never came on at all during the night. The breathing during the day remained easy; the bronchitic condition did not develop while adrenalin was used. In 1907 and 1908 she has continued to use the adrenalin injections every evening for a month in the hay season and the asthma keeps away while it is used. She still uses the weak cocaine spray for the nose. The whole complaint which used to trouble her seriously in causing bronchial stuffiness and great shortness of breath during the whole of the hay season seems now a very small thing.

I may say that I tried particularly in the first of these cases adrenalin by the mouth up to 15 minims, but it had not the slightest effect on the asthma when given in this way, nor did it show its dilating effect on the pupil.

Now, why should adrenalin act in this way on spasmodic asthma? As you know, Oliver and Schäfer [10] in this country showed that the medulla of the suprarenal gland contained a body which exerted a powerful action on the organism in contracting blood-vessels, raising the blood pressure and stimulating the heart muscle, and which the glands normally secrete into the blood-vessels. Takamine and Aldrich in 1900 simultaneously succeeded in crystallising out this active principle adrenalin, $C_9H_{13}NO_3$; also Abel (epinephrin) and Furth (suprarenin) similar or identical bodies.

Stolz [11] has worked out its chemical constitution and finds it to be o-dioxy-phenyl-ethanol-methylamine, $(OH)_2 C_6H_3CH(OH) (CH_2NH CH_3)$, not an exceedingly complex body after all. He has succeeded in preparing it synthetically and this artificial suprarenin or adrenalin has been shown by Biberfeld [11] to be identical in its physiological action with the natural product. For instance, 1-1000th milligramme of each preparation introduced intravenously

suffices to produce in rabbits of moderate size a just noticeable increase of blood pressure. Similarly both preparations give rise in dilution up to 1-500,000 to pupil dilatation in an enucleated frog's eye. In several other respects and in their toxic power both preparations were identical. Their only difference is in their effect on light; the artificial product is optically inactive.

A very large amount of experimental work has been done on the physiological action of adrenalin during the last few years, some of it somewhat contradictory. We may epitomise some of the results.

The blood pressure rises within three seconds of intravenous injection, chiefly owing to the contraction of the vessels of the splanchnic area and skin; and simultaneously the systole of the heart is enormously increased, and owing to the sudden rise of blood pressure the heart is slowed (through the depressor fibres of the vagus).

In the isolated mammalian heart, however, where the vagus is cut off, the force of the beat is augmented and accelerated, the action of adrenalin being stronger than that of any other drug in this respect, but its duration very limited (Dixon [12]). Slowing of the heart does not take place when the vagus is cut or poisoned by atropine. The rise in blood pressure is caused by a marked contraction of the peripheral arterioles, from direct action of adrenalin on their muscular coats, in the vessels of the skin, stomach, intestine, mesentery, and uterus; and the bladder vessels slightly. Adrenalin does not contract the vessels of the brain, or lung (pulmonary), or liver, which hence, when large doses have been given, become much congested with blood expelled from the splanchnic vessels. The retinal vessels may be seen to dilate with the ophthalmoscope. The vessels of the brain, lung, and liver are not innervated with vaso-motor fibres (Dixon [12]), and this is why they do not contract with adrenalin.

Gerhart [13] states that the vessels of muscle are scarcely changed in calibre. In an excised organ innervated by the sympathetic the contraction of the vessel walls may be demonstrated by perfusing blood containing adrenalin through the artery. The outflow through the vein almost ceases. Direct application of adrenalin to the mesentery often entirely obliterates the vessels; mucous membranes are similarly affected, as seen in chemosis of the conjunctiva, which gives place to pallor. Apart from the circular fibres of blood-vessels, other forms of unstriated muscle are spasmodically contracted by adrenalin. The muscles of the eye, innervated from the sympathetic, contract, causing dilatation of the pupil, withdrawal of the nictitating membrane, separation of the eyelids, and protrusion of the eyeball, exactly as after cocaine or stimulation of the cervical sympathetic.

The third nerve muscles are unaffected. The uterus contracts, also the vagina, the vas deferens, vesiculæ seminales, and external genitals. Contraction of some involuntary muscles is inhibited by adrenalin. The cardiac sphincter of the stomach and the internal anal sphincter relax. The movements of the stomach, intestine, and bladder are retarded or altogether arrested. As Cushny [14] observes, "adrenalin acts on a large number of forms of involuntary muscle, and apparently in diametrically opposite ways, causing constriction in many cases, but inhibiting it inothers."

It is noted that stimulation of sympathetic nerves has similar results in most cases. For instance, stimulation of the splanchnics causes (1) contraction of intestinal arteries; (2) relaxation of the muscular coats of the bowels. But adrenalin acts even after degeneration of the nerve endings, directly on the muscle fibres, and this would seem to indicate a fundamental difference in the chemical characters of the different muscle fibres.

How can we explain this fundamental difference to the action of adrenalin of different muscle fibres? It seems to me the key is to be found in Gaskell's [15] work on the system of efferent nerves which innervate the different parts of the vascular and visceral systems. He shows that all the nerves to the blood-vessels and organs do not leave the central nervous system uniformly, but in three great outflows, (1) cranial, (2) thoracico-lumbar, and (3) sacral, there being two marked gaps separating the three outflows caused by the interpolation of the plexuses for the innervation of the anterior and posterior limbs respectively. The thoracico-lumbar outflow or sympathetic outflow leaves the spinal cord in the anterior roots of the spinal nerves from the second dorsal to second lumbar inclusive, passing thence into the lateral ganglia of the sympathetic.

His own work and that of Langley, Anderson, and others enable Gaskell [16] to state definitely that from the thoracico-lumbar or sympathetic outflow arise:—

(1) All the nerves which cause contraction of the unstriped muscles of the skin, whether pilo-motor or not; (2) all the nerves which cause secretion of sweat glands wherever situated; (3) all the nerves which cause contraction or augmentation of the action of muscles belonging to the vascular system; (4) all the nerves which are motor to all organs derived from the Wolffian and Müllerian ducts, for example, the uterus, ureters, and urethra. It is essentially an efferent skin system.

On the other hand, the cranial and sacral outflow are concerned with the supply of nerves to the alimentary canal, they form essentially an efferent gut system in contradistinction to the sympathetic or skin system. The vagus or cranial outflow supplies the gut as far as the ileo-cæcal valve, the sacral nerves supply the gut beyond the valve—that is, the cloacal region which includes the large intestine and the bladder (except the trigone).

The motor nerves to the trigone, ureters, and urethra arise from the thoracico-lumbar outflow; they belong to the muscles in connexion with the Müllerian and Wolffian ducts and skin. The ileo-cæcal valve alone of all the gut is innervated by the thoracico-lumbar or sympathetic outflow. This has been recently shown by Elliott, and that it is in reality a sphincter muscle.

It will be found on examining the pharmacological evidence that all the involuntary muscles supplied by the thoracico-lumbar outflow are contracted by adrenalin. (Its action on the ileo-colic valve does not appear to have been investigated, but it may be confidently predicted that it will cause its contraction.) This generalisation that adrenalin stimulates or contracts muscles supplied by the sympathetic nerve, and those only, was borne in upon me when I first read Gaskell's anatomy of the lumbo-sacral outflow. I thought it was an original observation, but a few days after I found it had been discovered before. Thus Gaskell [17] says:—

One clue has arisen quite recently which is of great importance and must be worked out in the future—viz., the extraordinary connexion which exists between the action of the sympathetic nervous system and the action of adrenalin. This substance when injected into an animal produces the same effects as stimulation of the nerves which belong to the lumbo-thoracic outflow of visceral nerves, i.e., the system known as the sympathetic nervous system, which is distinct from both the cranial and sacral outflows of visceral nerves. The similarity of its action to stimulation of nerves is entirely confined to the nerves of this sympathetic system and never resembles that of stimulation of either the cranial or sacral visceral nerves.

He mentions another most important point which shows the intimate connexion between the adrenals and the sympathetic system from the point of view of the evolution of the latter system—namely, the fact that even adrenalin obtained from the elasmobranch fishes will produce in highest mammals all the effects known to occur on stimulation of its sympathetic system.

I cannot find, however, that Gaskell or any of the other authorities have noted the other equally important fact which the pharmacology seems to me to prove—namely, that adrenalin inhibits or relaxes all involuntary muscles supplied by the cranial and sacral outflows. All the vagus-supplied muscles are relaxed at once. This has been experimentally described for all the muscles in the abdomen supplied by the vagus, and from the effect of adrenalin in asthma there is no doubt the vagus-supplied bronchial muscles are inhibited in the same manner. The lungs originate as an outgrowth from the fore-gut. In the Dipnoi fishes, where they first occur, they can be seen to be a modification of the swim bladder of ordinary fishes. They naturally take the vagus nerve-supply of the rest of the fore-gut. The circular muscles of the bronchi have been experimentally shown to be contracted by the vagus as their motor nerve. What I postulate is, that this contraction is immediately inhibited by adrenalin and also as a corollary by strong stimulation of the sympathetic.

Neither the vagus nor sympathetic system has any nerve supply to the pulmonary vessels, arteries, or veins, and their variations in calibre must depend solely on the pressures within them. The vessels of the mucous membrane of the bronchial tubes are, however, supplied by the ordinary systemic arteries—the bronchial arteries, and these arteries in all probability possess vaso-motor nerve fibres like the ordinary arteries of the body. All vaso-motor nerve fibres are derived from the thoracico-lumbar sympathetic, and the presence of adrenalin in the blood will cause blanching of the bronchial mucous membrane simultaneously with the relaxation of the circular muscle fibres, and thus tend to remove the asthma even more completely than a simple relaxation of spasm.

When we reflect it is easy to see why the blood-vessels and circular fibres of these organs—bronchial tubes, small intestine, &c.—should be supplied by opposing nerves. Take the gut, for instance, when full of food and active in

peristalsis. The motor nerve for this peristalsis is the vagus, which is now in full work reflexly, as it feels the food inside. While digestion is taking place it will be an advantage to have all the blood-vessels relaxed, so as to promote the local blood-supply. Therefore while the vagus is stimulated the vaso-motor sympathetic is inhibited and thus the small vessels dilate. In the quiescent and empty gut when the vagus stimulation has ceased the sympathetic stimulation begins, causing the blood-vessels to contract actively with their circular fibres, and keep the gut blanched.

In the bronchial tubes, again, suppose an irritant gas, as SO_2, or irritant substance, as fine cotton fibre, has gained entrance. The irritation of the vagus sensory fibres causes the motor reflex spasm of the circular bronchial muscles tending to keep out further irritant. This vigorous action of the vagus inhibits the sympathetic vaso-constrictor nerves, and the bronchial mucosa becomes congested through dilatation of its blood-vessels. This free blood-supply will both help the production of mucus by the mucous glands and assist the closing of the smaller bronchia, and thus protect the alveoli from the entrance of the irritant.

As said before, the asthmatic reflex is in its essence a physiological and conservative process. When it seems to have good cause for its presence, as in the above example, we shall not be always justified in violently reversing it by the injection of adrenalin. But as a rule the asthmatic is pathological. He has too much vagus in his cosmos, and his sympathetic outflow is below par. We would like to touch up his own adrenal gland or his sympathetic nerve, and if we cannot get at these we can at least inject some other adrenalin into him and get the same result.

The effect of violent emotion in removing an attack of asthma is well known, and I have no doubt it is due simply to sudden violent stimulation of the sympathetic overcoming the vagus. If one suddenly meets a lion in the path the heart gives a bound and is immediately vastly accelerated: the skin blanches, a cold sweat breaks out, and "each individual hair stands on end"; the pupils dilate, eyes widen and stand out, and the blood pressure rises rapidly, as a good high blood pressure is useful to the organs of locomotion in these circumstances. All these signs, which are historical as those of fear, are exactly the same as those produced by stimulation of the sympathetic or injection of adrenalin. As we know also, in extreme fear the vagus and sciatic outflow are inhibited, peristalsis ceases, and the anal and vesical sphincters relax, as well as the cardiac sphincter of the stomach. Undoubtedly the whole vagus outflow is inhibited, including the bronchial muscles. The nervous system is far too busy to pay any motor attention to the efferent gut system when the efferent skin system and voluntary muscles and heart require so much more attention if life is to be saved from the lion. I have thought sometimes that a bad paroxysm of asthma might tend to cure itself by the downward pressure of the diaphragm actually pressing mechanically on the adrenal gland and stimulating it to get rid of adrenalin through the adrenal vein into the general blood stream.

Altrincham.

A NOTE ON DESICCATED CULTURE MEDIA.

BY E. T. THOMPSON.

(*From the Wellcome Physiological Research Laboratories, Brockwell Hall, Herne Hill, S.E.*)

I HAD been working on the desiccation of culture media for a considerable time, had completed my experiments, and put the method on a practical basis, when I heard that Mr. F. R. Chopping of Westminster Hospital had recently made a communication on the same subject before the Royal Microscopical Society. I think it desirable, therefore, to publish a note on the results of my own work

The preparation of small quantities of culture media is always a tedious process and usually attended with unsatisfactory results. It occurred to me that many of the culture media might be dried and reduced to a powder containing all the requisite solid constituents which would remain indefinitely in an unaltered condition. Investigators who only have occasional use for culture media could prepare a stock on a workable scale, dry the medium, and then keep it indefinitely, weighing out sufficient quantities for a few tubes or plates as required. I therefore determined to inquire into the practicability of such a method of preparation, and have obtained the following results by using culture media which had been subjected to the process of desiccation.

The culture media under investigation were nutrient gelatin, nutrient agar-agar, nutrient beef broth, and MacConkey's neutral-red bile-salt lactose agar. These were all evaporated to dryness and when made up to their original volumes with distilled water, and dissolved at 100° C., were quite clear, the gelatin, agar-agar, and bile-salt agar solidifying with their original firmness on cooling. The reaction of the broth before drying, which was + 15 acid to phenolphthalein, remained unaltered after treatment.

The agar-agar, gelatin, and broth were each distributed into test-tubes and sterilised; they were then inoculated with several of the pathogenic, saprophytic, and chromogenic bacteria respectively and without exception vigorous and typical growths were obtained.

The neutral-red bile-salt agar was distributed in Petri dishes and allowed to dry in the usual manner and then inoculated on the surface with a mixture of Bacillus typhosus, B. coli, B. subtilis, and B. megatherium by means of a bent glass rod. No difficulty was experienced in rubbing the surface with the glass rod; in fact, the rubbing was performed a little more vigorously than necessary in order to test the texture of the medium, but it remained unbroken. After 48 hours incubation at 40° C. typical colonies of B. coli and B. typhosus had developed, the coli colonies being red and the typhoid colonies being colourless. The B. subtilis and B. megatherium had not grown. The foregoing experiments show that the typical reactions may be obtained with this medium after desiccation and that its inhibitory properties are in no way impaired.

Conclusion.—From the satisfactory results which have been obtained it appears that this is quite a practicable method of storing culture media, the results obtained by its use differing inappreciably from those obtained by using media stored in the moist form. The possible value of such a method to public health officers or travellers in the tropics will be obvious.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

LARYNGOLOGICAL SECTION.

Exhibition of Cases and Specimens.

A MEETING of this section was held on May 6th, Dr. J. DUNDAS GRANT, the President, being in the chair.

The following were among the cases and specimens shown:—

Mr. HERBERT TILLEY exhibited a Penny removed from the Gullet of a young girl aged 14 years. It had lain 13 days just below the cricoid region of the œsophagus. The mucous membrane around the penny was very congested, and in parts slightly ulcerated. It was finally removed with difficulty with a Killian's long-toothed forceps. The patient left the hospital four days later.

Dr. H. J. DAVIS showed: 1. A case of Entire Excision of the Tongue in a man aged 45 years. The tongue was removed by Mr. D. J. Armour in 1909, and opinions were desired as to the possibility of adapting an artificial tongue. The patient is well, and speaks volubly, but is not easy to follow; he strangely pronounces "f" like "th," and speaks of his age as "thorty-thive." He cannot bite properly, and loses his food, as he never knows where it is in his mouth, but food or liquids go down the right way. (The general opinion of members was that a rubber tongue or plate was not very practicable.) 2. A man with a large Venous Angeioma implicating the Left Tonsil and Lateral Pharyngeal Wall; also a large Vascular Swelling on the Neck of the same side,

and evidently communicating with the former. When the patient lowers his head the tumours at once distend.

Mr. CHICHELE NOURSE showed a case of Epithelioma of the Larynx in a man, aged 69 years, 14 months after operation. A red growth occupied the anterior two-thirds of the left vocal cord. Thyrotomy was performed on Feb. 18th, 1909. The left vocal cord, ventricular band, and arytenoid were removed. Recovery was rapid. The patient remained well and had gained flesh.

Dr. STCLAIR THOMSON showed two cases of Radical Frontal Sinus Operation to show the conditions respectively 9 and 16 months after operation. Killian's method was carried out on the frontal sinus, and each patient also had an endo-nasal operation for suppuration in the ethmoid cells and maxillary antrum. The headaches have been, like all the other symptoms, entirely lost, and the patients now enjoy perfect health, never requiring a nose wash, as no trace of purulent discharge is visible in the nasal chambers.

The PRESIDENT showed: 1. A case of Infiltration of the Right Half of the Larynx of obscure nature in a woman aged 34 years. The swelling invaded the epiglottis and right aryepiglottic fold to the extent indicated, and a smooth, rounded, sessile swelling was also visible, apparently growing from the lingual surface of the base of the epiglottis. Hoarseness of three weeks' duration was present, but there were no physical signs in the chest. 2. A case of Odynphagia in a Tuberculous Subject, without any obvious disease of the larynx. The patient was a woman, aged 35 years. There were loss of voice and severe pain running up to the left ear during swallowing, and some ill-defined œdema on the outer surface of the aryepiglottic fold; otherwise the larynx was normal in appearance, as was also the movement of the vocal cords.

Dr. ARTHUR H. EVANS showed a case of New Growth, probably malignant, invading the right tonsil, soft palate, lateral pharyngeal wall, inner surface of the angle of the lower jaw, and adjacent portion of the tongue, in a man, aged 40 years. The case was shown to invite suggestions for treatment.

MEDICAL SOCIETY OF LONDON.

Ankylostomum Duodenale.

A MEETING of this society was held on May 9th, Dr. SAMUEL WEST being in the chair.

Dr. F. M. SANDWITH showed an interesting collection of lantern slides of Ankylostomum Duodenale, mostly taken from the published drawings and microscopic sections prepared by Professor A. Looss of Cairo. Anæmia due to the ankylostomum duodenale seems first to have been discovered in Europe among the miners of Anzin in 1802, though it was well known in Brazil so long ago as 1648. About the middle of the nineteenth century Dubini at Milan first recognised the worm itself; and very shortly afterwards Bilharz and others found the parasite to be very plentiful in Egypt and successfully proved there that it was the cause of "tropical anæmia." Until 1898 it was universally supposed that the larvæ of this worm, like most other parasites, entered man only by the mouth, but in that year Looss accidentally dropped upon his own hand in his laboratory a drop of water containing more than 1000 lively larvæ. Thereupon ensued redness and burning locally, and eventually anæmia and debility followed, and the eggs of the parasite were found in the fæces of the involuntary experimenter. He at once recognised the importance of this observation, but his belief was not shared by others, as it seemed too unlikely a thing to be possible that the larvæ should have entered his skin. He thereupon, after being cured of the infection, repeated the experiment purposely on another part of his hand, and was able to show the same local and constitutional results. His next experiment was to remove some of the skin as soon as possible after the death of a human patient, to warm it to 99° F., and to see if the larvæ would enter, but this they refuse to do because the skin became at once shrivelled. He then succeeded in applying a compress containing some larvæ to the leg of a boy aged 13 years one hour before the leg had to be amputated. It is needless to say that the boy had previously been examined and had been found to be free from this parasite. On examining the skin of the leg it was seen that the larvæ had penetrated the skin chiefly by the hair follicles, and so far as the compress had spread there was hardly a hair follicle free from the larvæ of ankylostomum duodenale. Photographs of the skin were shown by Dr. Sandwith at one of the British Medical Association meetings, but the possibility of skin infection met with no acceptance. A volunteer was then found whose fæces were examined for six weeks every day and invariably found to contain no evidence of eggs of the ankylostomum duodenale. On the forearm of this volunteer a drop of culture was placed, and he became infected so that the first egg was found in his fæces on the seventy-first day after the experiment. During the first month afterwards each specimen of fæces showed at least a dozen eggs and afterwards two or three dozen. Fortunately for the purposes of this experiment it is possible to make use of an analogous worm which infests dogs, the ankylostomum caninum. Looss carefully selected some puppies which were found to be free from disease, and applied to their skins a mixture of charcoal and fæces in which larvæ had been bred. The puppies died on the ninth day, and at the post-mortem examination anæmia was seen and many young worms were found in the duodenum, all immature and no adults, proving that the infection was recent, and practically the same result was achieved as when puppies had been fed on larvæ by the mouth. By cleverly infecting a series of puppies on three different days and then killing the puppies Looss was able to procure reliable sections of different stages of the disease, for the important thing was to know what happened to the larvæ after they had entered the hair follicles and how they succeeded in getting into the alimentary canal. After devoting some weeks of patient toil to this special investigation, Looss was able to prove that the larvæ, after entering the skin, got into the lymphatic vessels and later into the subcutaneous veins. Having thus entered the circulation, the larvæ were transported by the blood current to the right side of the heart, to the capillaries of the lungs, to the alveoli, to the bronchi, to the trachea, and to the larynx, where they wound themselves round the epiglottis and entered the œsophagus, stomach, and duodenum, which seemed to be their goal, for there they became sexually mature. Schaudinn confirmed this experiment on young monkeys and showed that the larvæ remained the same size from the time they entered the skin till they reached the lungs; as soon as they arrived at the air vesicles they began to grow rapidly. Dr. Sandwith assumed that the audience were perfectly well aware of the entry by the mouth and devoted his time to detailing the history of the discovery of the entrance of the larvæ by the skin. Dr. Sandwith laid emphasis on the importance of this discovery, which may have a far-reaching effect on the study of the entrance into man and the lower animals of parasites the life-histories of which are not yet elucidated fully.

In the absence of Sir Patrick Manson some slides of malaria cases were demonstrated by Dr. C. W. DANIELS, and Dr. W. CARNEGIE BROWN commented on some slides of tropical dysentery, after which the evening was concluded with a demonstration of microscopical sections of sleeping sickness cases by Dr. A. W. G. BAGSHAWE.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Congenital Talipes.—Difficulties in Prescribing and Wearing Glasses.—Exhibition of Cases and Specimens.

THE last meeting for the session of this society was held on May 6th, Dr. J. B. HELLIER, the President, being in the chair.

Dr. ROBERT BEATTIE read a paper on Congenital Talipes. He complained that while other parts of the body had made advances, little or no progress had been made in the deformities of the human foot, and he considered that this was due to various and conflicting views as to the cause. Reasoning from the origin of the acquired form (excepting the paralytic) to the congenital, he looked on it as due to perverted nerve action, and he summed up by saying: "Talipes is due to a vicious nerve habit, initiated in utero, the result of maternal impressions in a highly sensitive mother;" that a nerve habit could only be overcome by persistent opposition; and that in opposition to the opinion of recognised

authorities operative measures and the use of irons were rarely required.

Mr. MICHAEL A. TEALE read a paper on Some Difficulties in Prescribing and Wearing Glasses. He pointed out that in many cases the estimation of refraction was difficult, partly because the methods available were not exact, and partly because the patients themselves happened to be peculiarly intolerant of the optical defects of lenses. After briefly referring to the three chief methods in vogue—namely, the shadow test, ophthalmometry, and the use of trial lenses—he emphasised the fact that it was often only by averaging the results of several different methods that the margin of error could be reduced to reasonable limits. Certain difficulties in connexion with each method having been pointed out, attention was drawn to certain faults in the making-up of spectacles which were capable of causing discomfort, even though the prescription for the lenses themselves was correct. The faults dealt with were chiefly those of unintentional decentering, both optically and geometrically, together with undesirable prismatic and astigmatic effects. Brief reference was also made to the modern types of periscopic and toric lenses.

Dr. E. O. CROFT showed a Uterus removed by Abdominal Hysterectomy for Fibroid Tumour which was undergoing "red degeneration." The woman, aged 40 years, had two children several years previously. Menorrhagia, pressure symptoms, and recently much tenderness had been present. There was a large parovarian cyst on the left side. The fibroid situated in the posterior uterine wall was spherical and on section its central portion showed deep red colouration which extended in a star-like manner towards the periphery. Microscopic examination showed some degeneration of the myofibromatous tissues together with thrombosis of the smaller vessels.

Dr. T. CHURTON showed:—1. A Tabetic Patient with pupils dilated, non-oscillating, and immobile in convergence; vision good; no optic atrophy. 2. A man, aged 40 years, with Paralysed Right Face and Arm. On April 22nd the orbicularis oculi was completely paralysed (seven days after sudden onset); it was now acting in conjunction with the left, but not singly. The leg was not paralysed. The patient could repeat quite clearly words and short phrases, but could not answer questions intelligently.

Mr. H. LITTLEWOOD showed specimens of (1) Appendix removed containing a large number of gun shot; and (2) Malignant Disease of the Appendix, associated with a large abscess.

Mr. B. G. A. MOYNIHAN showed a specimen of Nephrectomy for Tumour with Continuous Hæmorrhage showing disorganisation of the kidney due to a silk ligature.

Mr. H. COLLINSON showed the Ovary and Fallopian Tube with Torsion of Pedicle removed from a congenital inguinal hernia in a patient aged six months.

Mr. L. R. BRAITHWAITE showed an Hour-glass Gall-bladder containing stones in the proximal and muco-pus in the distal compartment, removed from a woman aged 40 years who for the last five years had been treated as a case of "neuralgia" of the stomach.

Cases and specimens were also shown by Mr. JAMES J. ANNING, Mr. H. SECKER WALKER, Dr. E. F. TREVELYAN, Dr. E. ALLAN WILSON, Mr. W. GOUGH, Mr. J. F. DOBSON, Dr. W. H. MAXWELL TELLING, and Mr. TEALE.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Nephrectomy.—Coxa Valga.—Ununited Fracture of the Tibia.

A MEETING of this section was held on April 22nd, Mr. JOHN LENTAIGNE, the President, being in the chair.

Dr. R. ATKINSON STONEY read an account of two recent cases of Nephrectomy. The first case was that of a man who was thrown from a bicycle on to his right shoulder; he was rendered unconscious for a few minutes, but was then able to go home. He remained in bed for about a fortnight suffering from a certain amount of pain in the right side, but it was not till he began to go about that he first noticed blood in the urine. He then went to hospital, where he was kept under observation for three weeks. During this time his urine contained large quantities of blood, which was found by Luys's segregator to come from the right side. At the operation the kidney was discovered to be torn almost in two at the hilum and the lower half was in a state of pulp. The second case was one of a girl who had been passing blood and tubercle bacilli in the urine for over six months. The urine was segregated by Luys's segregator on two occasions, and both times the urine from the right side was normal, while that from the left side contained blood, pus, and tubercle bacilli. At the operation the kidney was found to contain a small cavity (about one drachm of capacity) in the upper half, representing the base of one of the pyramids. Under the microscope the wall of this cavity showed general round-cell infiltration and masses of red cells, but no definite tubercles. No blood, pus, or tubercle bacilli could be found after the operation, though several examinations of the urine were made. Dr. Stoney commented on the curious discrepancy between the symptoms and pathological findings in the two cases.—Mr. SETON S. PRINGLE said, with regard to the second case, that he had had two cases of a similar nature, in both of which the kidney was exposed, and in neither was he able to demonstrate tuberculosis. Both patients made perfect operative recoveries, but one was still—18 months after the operation—complaining of pain and frequency of micturition, and passing some pus; while the other one, when seen two months ago, was in practically the same condition as before the operation, and was still passing purulent urine. He would suggest that in the case of the so-called tuberculous kidney it was the ureter that was chiefly involved.—The PRESIDENT said that if there was a condition in which the treatment by injection of tuberculin was really valuable it was in tuberculosis of the genito-urinary organs, especially the kidney. He had seen cases too ill for operation which improved to a wonderful extent, although the injections were carried out without being controlled by the opsonic index.—Dr. STONEY, in reply, said that against the idea of the ureter being involved was the fact that, although he did not remove any portion of the ureter, there was a complete cessation of all symptoms from the time of the operation. For ligatures he used catgut prepared by the iodine method, and had always found it sterile. He had found the segregator absolutely successful in many cases. In the use of it the position of the patient was important. If the patient was put sitting up in a gynæcological chair, so that the legs were nearly at right angles with the body, there was no possibility of urine passing from one side to the other, unless the bladder became over-distended.

Mr. SETON PRINGLE read a paper on Coxa Valga, with a report of a case associated with Ankylosis of Both Hips. He first dealt with the etiology, symptoms, and treatment of this rare deformity, and laid stress on the importance of expert skiagraphy in diagnosis. He then exhibited skiagrams and photographs taken before and after the performance of a subtrochanteric linear osteotomy on both femora. The case was complicated by ankylosis of both hips, due to arthritis caused by septic absorption from a large superficial burn, and yet the operation gave a quite satisfactory result.—The PRESIDENT said that the condition was a very rare one; its discovery was entirely due to the use of radiography.—Mr. A. J. BLAYNEY said that, in cases of congenital dislocation, the skiagrams seemed to show the neck as being a direct prolongation of the shaft.

Mr. WALTER C. STEVENSON reported a case of Ununited Fracture of the Tibia treated by Wiring. A skiagram taken four weeks after the injury showed a spiral fracture three inches long in the lower third of the right tibia and almost complete absence of bony callus. In spite of the mobility of the fragments, an attempt at reduction was only partially successful owing to the shortening of the muscles. The fracture was therefore exposed by a curved flap, which included the periosteum of the inner side of the tibia. When the broken surfaces were got into good apposition, after tenotomy of the tendo Achillis, both fragments were drilled in two places about an inch apart. Wires passed through the drill holes were crossed and tightened in front and then made to encircle the bone completely. The subsequent treatment consisted in an early use of the limb, supported by a removeable plaster splint which transmitted the weight of the body from the ground to the tuberosities of the tibia and which permitted of the parts being massaged. The progress of the formation of bony callus and the good

position of the fragments were verified by a series of skiagrams. In 23 days after the operation a fair amount of osseous tissue was apparent around the fracture, and about a month later the patient, wearing a boot with lateral steels, was able to resume his occupation.—The PRESIDENT said that the method of treating fractures by massage was good enough where there was no deformity; but where there were much deformity and no apparent attempt at union undoubtedly something had to be done like what Mr. Stevenson had carried out. He had been rather afraid that some harmful result would come in cases where he had used wiring circularly round the bone, but no harm had ever followed. He had recently treated a fracture of a girl's tibia by wire and plate. Suppuration followed, but he found that she had a habit of passing a hairpin down under the dressing when the surface itched. He cut down and removed the wire, and the girl walked about at once.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on May 5th, Mr. C. J. Jacomb-Hood being in the chair.—Dr. F. Hinds (Worthing) was elected President for the ensuing year.—Dr. Walter Broadbent showed a case of Right Hemiplegia in a child, aged 7 years. The onset had been gradual during the last six weeks. Double optic neuritis was present. There had been vomiting every few days; there was no headache. There was no deafness or history of ear disease. It was supposed that there was a subcortical tumour in the left parietal lobe.—Mr. H. G. Mallam showed a case of Leucoderma in a girl, aged 14 years. There was a small patch of white hair over the right ear; the middle half of the eyebrow of the same side, and the upper eyelashes were white. There was also an imperfect downward coloboma of the corresponding iris. The lower half of the right retina was paler than the rest. The white colour of the hair, &c., was supposed to have followed a stroke by lightning.—Dr. E. Rivaz Hunt showed a case of Osteitis Deformans in a man, aged 58 years. Up to 14 years ago he had excellent health, and was at that time 5 feet 3½ inches in height and capable of doing heavy work. Fourteen years ago he had influenza, and at about this time his bone trouble began. The legs were most affected, the skull not markedly, and the disease was steadily progressing.—Dr. A. W. Williams showed a case of Darier's Disease and sections of the Papules. The patient was a man, aged 39 years, and had been under treatment for six months, the disease having lasted for three years. His present condition was that dome-shaped, flat surfaced, discrete, hemp-seed shaped papules covered the greater part of the trunk, and were most marked in the middle line, both posteriorly and anteriorly. All treatment had failed to remove the papules, the only result being to plane down some which were acuminate and to remove some complicating pustular lesions. The sections showed: 1. Horny layer; here and there thickened plugs were seen to dip down into the rete and also to be elevated above the surface. The centre of the plugs consisted of a hyaline mass, the lower part of which was made up of imperfectly coalesced round bodies. 2. The granular layer was thickened under the plugs and contained a number of Darier's round bodies, which showed a slight affinity for acid stains. 3. The corium showed a slight infiltration of round cells in the neighbourhood of the vessels of the papillary layer below the region of the horny plugs. The intractable nature of the disease and its rarity were commented upon.—Mr. H. N. Fletcher showed a Pregnant Tube, in the outer third of which the ovum had developed, and from which the fœtus had escaped through the ostium abdominale, leaving a cavity lined by the shaggy chorionic membrane. Attached to the end of the tube was a peritubal hæmatoma about the size and shape of a duck's egg and with smooth fibrinous outer wall. The patient had been suddenly taken, during an attack of scarlet fever, with a severe pain in the left iliac fossa and rectum. Continuous loss of dark blood per vaginam followed this for the seven weeks she was in the fever hospital. Recurrent pains in the left iliac fossa and pain on micturition were present for the first fortnight, leaving a dull ache thereafter. There was no period of amenorrhœa The initial pain occurred seven days after an entirely normal period.—Dr. F. G. Bushnell contributed a note on the Wassermann test for Syphilis and other diseases.—Mr. A. J. Hutchison read a paper giving notes of cases of Intracranial Complications due to Middle-ear Suppuration. (We hope to publish this paper in a forthcoming issue.—ED. L.)

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held at the Royal Infirmary on May 10th, Dr. W. Ward-Smith being in the chair.—Mr. T. Wilton Thew read a paper on Oral Sepsis considered from a Dental Point of View, as an introduction to a discussion on the subject. He said: This is a subject which demands the combined attention of doctor and dentist. As regards children, one of the chief things to be considered is the question of diet. Dr. Wallace insists on dietetic arrangements which will leave the mouth physiologically clean. After some teeth have appeared the food should be of a consistency such that it will demand the use of the teeth. The food should consist of, or at any rate include, substances of a hard and fibrous nature. Apples, crust, and even bone are excellent things to scour the teeth and jaws, and help to develop the bones and muscles of mastication. Dental caries is the principal cause of oral sepsis in children. The importance of having temporary teeth filled, and filled early, cannot be exaggerated, for the following reasons: (1) The smaller the decayed spot, the easier and more satisfactory it is to fill; (2) permanent teeth are more likely to be preserved if they come into a mouth which is free from caries and clean; and (3) decayed temporary teeth very readily produce alveolar abscesses. The first permanent (six-year old) molar is very apt to decay and causes the acutest suffering. In adults the study of oral sepsis is largely the study of pyorrhœa alveolaris. This is a chronic progressive destruction of the tooth socket, generally accompanied by the formation of pus. The cause is irritation of the gum margin, long continued and incessant. The deposit of tartar round the necks of the teeth is the usual form of irritation. No specific micro-organism has been discovered. The disease is accompanied by systemic symptoms, the chief of which are anæmia and various intestinal disorders. *Treatment:* Vaccine treatment is still *sub judice*, and so far has not given very satisfactory results. The principal point in the treatment is the removal of the tartar, and this requires care and patience. After scaling, a dental atomiser should be used with hydrogen peroxide. The teeth should be brushed with a simple chalk tooth-powder night and morning and after every meal. Systematic massage of the jaws and gums must be carried out. For advanced cases there is only one cure—extraction.—Dr. W. Wrangham opened the discussion from a medical point of view, and gave many instances of interesting cases due to oral sepsis.—Dr. A. Bronner pointed out that oral sepsis was very closely connected with diseases of the nose and throat, especially otorrhœa and antrum disease.—Dr. T. J. Wood did not agree with feeding children on hard substances, and he asked Mr. Thew why it was that dentists were so averse to extracting teeth when an alveolar abscess had formed.—Dr. Ward-Smith said it was appalling the number of children one saw with septic mouths.—Dr. A. C. F. Rabagliati, Dr. Taylor, Dr. H. J. Campbell, Dr. J. Metcalfe, Dr. F. W. Eurich, Mr. F. W. Goyder, and Mr. H. A. Mahony also spoke.—Mr. Thew then replied.

ASYLUM WORKERS' ASSOCIATION.—The annual general meeting of this association will be held at 11, Chandos-street, Cavendish-square, London, W., on Wednesday next, May 25th, at 3 P.M., when Sir William J. Collins, M.P., President of the association, will take the chair. The annual report will be submitted, officers elected, and presentations will be made of (1) medals for long and meritorious nursing service in asylums; and (2) an illuminated address to the President, and a testimonial to the honorary secretary in commemoration of the passing of the Asylum Officers' Superannuation Act. The Rev. Canon Sheppard, sub-dean of the Chapels Royal; Sir T. Clifford Allbutt, Regius professor of physic, University of Cambridge; Sir James Moody; Dr. F. Needham, Commissioner in Lunacy; Professor W. Bevan-Lewis, President of the Medico-Psychological Association; Mr. J. McD. Henderson, M.P.; and Mr. Charles H. Roberts, M.P., have intimated their hope to be present, in addition to members of the executive committee.

Reviews and Notices of Books.

Die Experimentelle Pharmacologie als Grundlage der Arzneibehandlung. Ein Lehrbuch für Studirende und Arzte. Von Dr. HANS H. MEYER, Wien, und Dr. R. GOTTLIEB, Professoren der Pharmacologie. Mit 61 Textillustrationen und 1 farbigen Tafel. Berlin und Wien: Urban und Schwarzenberg. 1910. Pp. 483. Price M. 12.

THIS excellent treatise on Experimental Pharmacology as the Basis of Therapeutics, or the treatment of disease by means of drugs—using these terms in their widest sense—is dedicated to two veterans—investigators who have left their mark on the progress of medicine, pharmacology, and therapeutics. Instead of dealing with the drugs themselves and their actions on the body, the authors have adopted the plan of taking the great systems of the body, and narrating the action of drugs on them somewhat in the following order: Pharmacology of the motor nerve endings, the central nervous system, sensory nerve endings, vegetative system, the uterus, the circulation, sweat secretion, temperature, antipyretics, and the causes of disease, which are dealt with by Professor Gottlieb; the pharmacology of the eye, digestion, respiration, urinary secretion, metabolism, muscles, blood, and inflammatory processes by Professor Meyer; 17 sections in all, with many subdivisions in each.

Dealing with pharmacology of motor nerve endings, Professor Gottlieb gives a full account of the constitution, actions, characters, mode of action, and applications of curare as a typical elective poison; and then he proceeds to consider other substances which have a similar action—e.g., certain ammonium bases, such as tetramethylammonium. Then he discusses bodies, such as guanidin, which, instead of paralysing these nerve endings, excite them. Drugs which act on the central nervous system may either excite or paralyse, or, to use the old terms, they are "excitants" or "sedatives," but they cannot cause qualitative changes. They, however, produce an endless variety of active symptoms, either coincident or successive, according to the sensibility of the several parts of the central nervous system. Strychnine is first taken as a typical drug which exalts the reflex excitability, more especially of the spinal cord. The reflex tetanic effect is due to the action of the drug on the receptive neurons, greatly increasing their excitability. This is not all, however: it sets aside as well some inhibitory apparatus in connexion with these neurons. It also increases the excitability of the central apparatus, the sense of vision and some other senses, and also the respiratory centre, and this is a most important practical factor in its use in certain diseases. It is rather remarkable that while the reflex excitability in the frog is increased for tactual stimuli by strychnine, chemical cutaneous and other painful stimuli, e.g., cutting, are without effect—i.e., the threshold is lowered only for certain stimuli, not for all. This is corroborative of the work of Sherrington on spinal reflexes. Finally, strychnine produces exhaustion and paralysis. Then follows a full account of its therapeutical applications, a general history of the bodies known as alkaloids, and a full discussion of other drugs which produce "spasms," either clonic or tonic—the latter discharged from the cord, and the former, the epileptic form, from the higher nerve centres.

A very full account is given of the actions of caffeine—which is pure excitant—and camphor, the marked effect of both on the nervous respiratory apparatus, and the valuable effects on the brain of such stimulants in the narcosis of chloral hydrate, paraldehyde, or alcohol. But both excitatory and depressory phenomena may occur as the results of the use of a drug, of which atropine is a typical example. The danger of scopolamine as a sedative or soporific, owing to its marked action on the respiratory centre, is pointed out. The morphine group is next thoroughly considered. Morphine is conspicuous amongst soporifics in this respect, that its pain-stilling qualities are specially marked. By its use it is not possible to reduce the excitability of the cerebrum and spinal cord to the same extent as can be done by narcotics of the alcohol and chloral group. These latter drugs first affect the cerebrum, then the cord, and lastly the respiratory centre. With morphine the diminution of excitability passes from cerebrum to the respiratory centre, while that of the cord is depressed to a very much less extent. Therapeutically morphine is especially useful for annulling pain; as an analgesic it diminishes pain with doses which leave unaffected the motor centres. Equally sensitive is the respiratory centre and the apparatus involved in coughing. It is primarily an analgesic, and for combating pain no other drug can replace it. As a soporific it must be given in larger doses. Its pharmacology and therapeutical applications are dealt with fully, yet tersely. Then follows a short discussion on morphinism and the actions of codeine, dionin, and heroin. The alcohol group is dealt with by Professor Meyer. Alcohol is a protoplasmic poison; its effects are least obvious on animals with a lowly developed central nervous system. Its so-called excitatory, stimulating, and paralytic effects are considered, and the final conclusion is reached that, apart from its toxic action, it can be regarded as a substitute for food, and as such can be used in disease.

Anæsthesia by inhalation and the volatile anæsthetics are next considered, and a careful comparison is instituted between the physiological and therapeutical actions of ether and chloroform. A very full account and analysis of the causes of death under chloroform, and of its remote effects resulting in degeneration of tissues, are given. The author alludes to the percentage of chloroform that need be present in blood to induce narcosis, and the very slight increase of this amount that may produce sudden death from heart failure. No such narrow margin obtains in ether narcosis. In view of the recent recommendations of a Royal Commission on the subject this chapter is of particular practical importance, and should be carefully studied both by surgeons and by those who have to administer volatile anæsthetics. Nitrous oxide and bromethyl are then dealt with, and next the hypnotics of the alcohol group are fully discussed, as are chloral and its allies, chloramid, isopral, paraldehyde, urethan, hedonal, sulphonal, trional, veronal, proponal, bromural, and others. The chapter is rounded off with the subject of "Theories of Narcosis"; and the researches of Overton on the part played by the solvent action of fats and lipoids on certain of these narcotics, and the distribution of chloroform in the several tissues of the dog during chloroform narcosis, as determined by the important observations of Nicloux of Paris, are naturally included. As the salts of bromide have some actions resembling the action of narcotics on the cerebrum they are next considered, and attention is called to the relatively large doses of these salts that are required to obtain a "favourable therapeutic action," and to the retention of bromine salts for a long time in the body, and the practical importance of both facts in the administration of these drugs. The subject of the sensory nerve endings necessarily leads to the study of local anæsthetics, to the effects of compression, anæmia, and the action of cold. A full and careful account is given of cocaine as an elective drug, which paralyses sensory nerve endings without any previous marked excitation of these endings. The many compounds of, and substitutes for, cocaine are alluded to, but only a few lines are given to stovaine, a brevity which just at this time is a little tantalising.

Professor Gottlieb retains the old term "vegetative nervensystem"—a term still used in Germany, but little used in this country—as opposed to the "animal" or "voluntary nervous system." It practically is identical with our term "involuntary nervous system," and includes the efferent nerve fibres passing to smooth muscle as well as those nerve fibres that supply the heart. He prefers to retain this term, and he calls "autonomic" only that part of the "vegetativen nerven" which does not take its origin from the sympathetic chain of the sympathetic neurons, a use of the word "autonomic" different from that intended by its sponsor, Professor Langley, who first used the term. This definition naturally leads to the consideration of the actions of a vast number of drugs, such as nicotine, ergotin, adrenalin, artificial cholin, muscarin, pilocarpine, &c. For the ophthalmic surgeon there is a specially useful review of the action of drugs on intra-ocular pressure, while for the gynæcologist at a later stage there is an admirable chapter on the uterus. Over 40 pages are devoted to the digestive system, including both digestion and absorption. When absorption of drugs takes place from the rectum they produce their effect rapidly, because when so absorbed they pass directly into the hæmorrhoidal plexus to the hypogastric vein, entering the general blood stream without traversing the vena portæ and the liver. Emetics and purgatives and allied drugs come into this chapter. Magnus has shown by the X ray method that morphine has a remarkable retarding effect on the emptying of the fundus of the stomach; food may remain 8, 12, or 24 hours in the stomach. Hence it is inadvisable, because of the fermentative processes that ensue, to administer this drug in motor inefficiency from pathological causes—e.g., catarrh or ulcer of the stomach. To the circulation over 80 pages are devoted. There is an excellent *résumé* of the main physiological points to be noted in the heart and blood-vessels, and the whole question of cardiac remedies and poisons (extra-cardiac and intra-cardiac) is fully gone into, and again the pre-eminent position of chloroform as a cardiac depressant, as studied in the excised heart of a frog, is emphasised. As a paralysant of the heart its toxicity exceeds that of bromethyl 12 times, ether 48, and alcohol 132—i.e., the molecular concentration of these drugs must increase in these ratios to obtain the same action as chloroform on the isolated frog's heart as determined by Diebella. Camphor as an excitant of the first order in acute cardiac failure is strongly recommended. A full account is given of the action of alcohol on the heart and of adrenalin and digitalis; caffeine is said to exert its chief influence on the circulation through the vasomotor centre. As to vaso-dilators, of which amyl nitrite is the type, there is a full, practical, and commendable account.

We have not the space to accompany the authors in their equally lucid, practical, and scientific account of the pharmacology of the other systems enumerated at the beginning of this review, but we would draw particular attention to the last chapter (Chapter XVII., pp. 419–483) on antiseptics, anthelmintics, and specific "disinfectants"—e.g., quinine and its action on the lower protoplasmic beings and on the organism of malaria. This chapter also deals with the drugs employed—alas unsuccessfully—against trypanosomes, with the action of salicylic acid in rheumatism and of mercury in syphilis, and lastly, with the whole question of serum therapeutics, toxins, antitoxins, immunity, and the treatment of diphtheria and tetanus by specific sera.

We have great pleasure in commending this attractive, scientific, and practical treatise to the consideration of pharmacologists, physiologists, and practitioners; and we hope that ere long, both in this country and in America, it may be presented to those who unfortunately do not read German easily, in the form of an English translation, preferably by one who himself is both a pharmacologist and a practitioner of medicine.

An Elementary Manual of Statistics. By ARTHUR L. BOWLEY, M.A., Reader in Statistics, University of London. London: Macdonald and Evans. 1910. Price 5*s.* net.

Mr. Bowley's book supplies just the kind and amount of information that is required in an elementary treatise on statistics. Clearly and concisely written, as befits the work of a university teacher, it deals in masterly style with some of the more difficult problems that perplex the beginner whose mathematical equipment is not of the best. The book should certainly be in the hands of every public health officer, and it may confidently be recommended, perhaps in preference to the more advanced manual by the same author, as a text-book for the use of students of medicine who are candidates for diplomas in public health. It has been compiled for the needs of those who desire a useful practical acquaintance with statistical methods and results without the necessity of undertaking mathematical analysis, and is designed as a first course in statistics for students intending to proceed further with the science.

The subject matter is arranged in two parts. The first part deals with elementary methods and with such technical terms and ideas as are indispensable in the handling of numbers on a large scale. In the second part, which is intended as a guide to official statistics, the origin of many of these is shown, their adequacy is criticised, and some of their more important results are discussed. But one of the principal features in this volume of not more than 210 pages is the inclusion of a valuable series of lessons, some of which are apparently original, on the various applications of the subject. In these the author has taken pains to discriminate between the right and the wrong use of statistics, as well as to discourage the piling up of irrelevant tables and the construction of merely pictorial diagrams—a practice which sometimes leads to erroneous and even mischievous conclusions. Among the chapters in Part I. which relate to the general principles of the science, those treating of the nature of published statistics and the rules for their use are deserving of particular attention. The chapter on accuracy and approximation is also full of instruction, and so is the chapter dealing with the modern methods of statistical analysis. In Part II. the author's weighty remarks on the population census will repay careful perusal, especially in view of the next enumeration in April, 1911. The chapter on vital statistics, although short, is replete with useful hints for the official guardians of the public health who are charged with the duty of reporting on the local prevalence and fatality of the various kinds of disease. In his remarks on the many problems concerning sickness and mortality which naturally come within the province of medical officers of health it is gratifying to notice the author's willing testimony to the effect that "in many districts these officers present admirable annual reports, tackling the questions of most importance in their localities with statistical and professional skill."

Very interesting and instructive are the author's remarks on the application to particular cases of the general principles laid down in his earlier pages. Commenting on the risk of errors in definition which pervade the science of statistics, errors which may affect the apparent death-rate from any cause, as well as the rates of "morbidity" and of "case fatality," he points out that these may arise (1) from intrinsic difficulty of classification and incomplete "standardisation of description"; (2) from unconscious personal bias in the practitioner; (3) from the presence of

two diseases together or of a disease and an accident; or (4) from the desire to avoid mention of the existence of such a disease as, e.g., alcoholism. In almost all vital statistics the risk of *spurious accuracy* is considerable. "In the practical question," he continues, "as to whether one rate is greater than another, after the classes concerned have been made similar, there remains natural variation; if all known circumstances were the same, differences would still be found. All records of births, deaths, marriages, sickness must be regarded as *samples*: the greater the number of persons the more accurate the averages obtained from the sample. The only non-mathematical test of this accuracy is the test of subdivision" ..... "a great number of differences that are remarked on prove, on mathematical examination, to be only the result of chance variation, and to be no more remarkable than, say, the throwing of double dice twice in succession." In the author's opinion there is much to be said for the establishment of a medical mathematical office, to which statistical data could be sent for examination, just as bacteriological tests are made. The useful and suggestive chapter on vital statistics is concluded by showing that it is only when approximate constancy is attained over a series of observations, as in the case of the general birth-, death-, and marriage-rates, that statistics can properly be applied to the elucidation of problems and the tracing of cause and effect.

Many of our readers have been interested by the excellent paper of Dr. J. M. Troup and Mr. G. D. Maynard upon modern statistical methods, which we published last week. We therefore know that there is growing up among medical men a feeling that the study of mathematics is playing a more intimate part in medicine than heretofore. We ourselves feel that this is the case, and have pleasure in commending Mr. Bowley's book to what should be a large and growing class of readers.

Traité de l'Alimentation et de la Nutrition à l'Etat Normal et Pathologique. Par le Docteur E. MAUREL, Médecin principal de réserve de la Marine; Professeur à la Faculté de Médecine de Toulouse. Troisième volume: Ration de la grossesse, de l'allaitement et du travail; Influences qui modifient toutes les rations; Indications pratiques sur les aliments d'origine animale et végétale. Paris: Octave Doin et Fils. 1909. Pp. 700. Price 14 francs.

THIS is the third and concluding volume of the author's treatise on Alimentation and Nutrition in Normal and Pathological States. In studying the needs of the woman during the periods of pregnancy and lactation by means of the observation of pregnant animals he has been able to determine that there exists a very definite relation between the amount of food taken by the mother and that required for her own nutrition and that of the fœtus. With regard to lactation, for example, he concludes that the nursing mother, besides the amount of nutrition requisite for her own needs, as a rule consumes an amount of food exactly equal to that required by the fœtus after it is first weaned. The precise amounts required will naturally vary in individual cases, but as to the correctness of the principle the author has no doubt.

The researches which Professor Maurel has carried out on the influence of climate and the seasons on the needs of the organism form a very useful basis for the next section in this volume, which deals with the influence on nutrition of the temperature of the air. In relationship to this he has investigated also the effect of altitude. The influence produced by work, both physical and intellectual, is next considered, and in this study much assistance has been derived from the researches of M. Lefévre and M. Fleury. After the section dealing with the effect of work, the influence of the winds, the clothing of the body, and the character of the habitation are discussed in detail. As a result of these studies not only can the actual needs of the human organism be determined, but the exact quantities of the various substances, both mineral and organic, necessary to satisfy these needs can, the author holds, also be arrived at.

The second part of this volume is concerned mainly with a very detailed study of numerous articles of food and varieties of diet. In these chapters the author has given a precise account of the modifications produced in different foods as a result not only of their preservation, but also of the preparation they undergo before they are taken into the body. This represents a very large amount of work, for not only are all the substances derived from the animal kingdom considered, but also all those of vegetable origin. In this part of the work the author gives for each article of food considered, whether animal or vegetable, its composition, its waste constituents, the quantity which corresponds to the needs of the various tables of diets, the modifications produced by the different methods of preparation, and lastly, the nutritive value of each portion so prepared. In order to bring to a practical point his researches Professor Maurel has also added a section in which he deals with the dietary needs of various communities such as schools, the army, the navy, prisons, and restaurants.

In conclusion, he surveys the alimentation of France from the economic point of view, taking into account the nutritive and commercial value of the various foodstuffs produced. As a result of his investigations he furnishes some indications upon the needs of the country, upon the foodstuffs which are best able to satisfy those needs, and lastly, upon the relations existing between the nutritive values of these foods and their commercial value to the producer. The whole treatise forms a work of great interest and of great value, and we congratulate the author upon the termination of his labours and upon the excellence of the work he has done.

Preparatory and After Treatment in Operative Cases. By HERMAN A. HAUBOLD, M.D., Clinical Professor in Surgery and Demonstrator in Operative Surgery, New York University; and of Bellevue Hospital Medical College, New York, &c. With 429 illustrations. London and New York: D. Appleton and Co. 1910. Pp. 650. Price 25*s.* net.

RECENT methods employed in surgery require an elaboration of technique utterly unknown even a few years ago, and this very elaboration, while primarily imposing greater responsibility on the surgeon, also requires that all those who assist in the care of the patient before, during, and after the operation should be well acquainted with the principles which govern modern practice. In hospital work this is generally easily managed, but when the surgeon has to operate in a private house it may be difficult to ensure that the practitioner to whom much of the after-treatment will fall is thoroughly conversant with the latest developments of surgical ritual. Dr. Haubold has written this treatise chiefly with the object of educating the general practitioner in the methods commonly used by surgeons at the present time, and he has gone far to achieve success in this matter. It is hardly necessary to say that there can be no such thing as perfection in the writing of a book like this. Every surgeon has his own methods and lays stress on some points which may appear to other surgeons trivial and unimportant. If a surgeon meets with an assistant versed mainly in methods other than his own, he is likely to be dissatisfied, and in the same way any book on the subject of

surgical technique is sure to be found wanting in some details by every expert reader.

On the whole, little has been omitted that should have been inserted, and we approve of most of the advice given, but we must confess that there are at least a few points in which we think directions given are unwise. There is always a tendency to over-elaborate any method employed, and therefore, though we cannot definitely say that any of the procedures advised to attain asepsis is absolutely unnecessary, we think it important to point out that the employment of an unnecessarily elaborate technique is likely to defeat the very object for which it has been devised. When the student and others who have to assist at operations are told that every step in a complicated course of procedure is absolutely essential for the attainment of asepsis, there is no little risk that that very elaboration will dishearten them, when they will fail to reach a degree of asepsis which was easily within their power. The essentials should be taught; the less essential points, if mentioned at all, should be clearly described as merely addenda desirable when possible. We have no intention of going through this work and pointing out where we think the author has over-acted his part, but we will mention one case at least. He advises that the surgeon before performing an operation should disrobe completely and dress himself in a canvas or duck suit, consisting of loosely-fitting trousers held in place by means of a draw-string at the waist, and a sleeveless blouse tied with tapes in front. Over this, of course, aprons are worn. Now, we have not the faintest wish to attempt to depreciate the value of cleanliness in operations; we hold firmly to all the tenets of the creed of asepsis, but we must be allowed to express the opinion that such a radical change of clothing is quite unnecessary. Perfect results are obtainable, and are obtained, with fewer precautions than these, and we cannot doubt that the definite advocacy of such precautions tends to defeat itself.

The book is very fully illustrated—in fact, we may say that many of the illustrations are absolutely unnecessary. Nowadays, illustrations reproduced from photographs are very cheap, and within the last few years there has been no little tendency to overdo the introduction of these illustrations. For instance, gauze pads, "sponges," or "wipes," as the author calls them, are of great value in operations, but we think that nine illustrations, four of which occupy nearly two-thirds of a page each, are hardly needed. Still, the book well serves its purpose of giving instruction in the methods of modern asepsis, and success in so laudable an object justifies the lack of a sense of proportion which we find in its compilation.

Food Inspection and Analysis. By ALBERT E. LEACH, S.B., Chief of the Denver Food and Drug Inspection Laboratory, Bureau of Chemistry, U.S. Department of Agriculture; formerly Chief Analyst to the Massachusetts State Board of Health. Second edition, revised and enlarged. New York: John Wiley and Sons. London: Chapman and Hall, Limited. 1909. Pp. 954. Price 31*s.* 6*d.* net.

IN the matter of food laws the United States of America have taken perhaps the most drastic course of any civilised country. In June, 1906, the new national food law was passed, which not only regulates commerce in foods between State and State, but controls also their manufacture and sale and their importation from foreign countries. The Act is particularly stringent in regard to imported foods and to substitutes and preservatives. It requires above all things an honest label. Opinions differ as to whether this law presses too severely in many directions, and certainly complaints have been numerous as to the hardships which it is calculated to inflict upon manufacturers of certain classes of foods. The Government, however, have adopted a firm attitude, and the Act continues in operation without any serious amendments having been made. It is a great legislative experiment, and its results are being watched very carefully, and equally by public health authorities and by the industries concerned. The step has necessarily thrown upon the analyst an increased responsibility and an increased activity. He has had to follow carefully the standards laid down, and he has had to make himself familiar with all new methods of analytical procedure adapted to the new legislative requirements.

The first edition of Mr. Leach's authoritative work was issued in 1904, and a review of this edition appeared in these columns in October of that year. The great movement in favour of a stronger system of food control in the United States was consummated after the work was issued, and this fact has called for a second edition, which should deal with the new standards adopted, and with the new and improved methods of analysis which progress has substituted for many old ones. The book in its present form deals with a wide variety of subjects included in analytical procedure, and many analysts in this country will read with interest the sections on meats and meat extracts, flour (including methods for the detection of bleaching), the analysis of potable spirits, tea, coffee, cocoa, ice-cream, and the methods for detecting and estimating preservatives. There are instances, of course, which are clearly only applicable to United States laws, but in spite of that fact the book is certain to find a wide patronage in this country because its analytical chemistry comprises methods of accuracy and precision which have received endorsement by the author's own careful practical work.

Fifth Annual Report of the Henry Phipps Institute for the Study, Treatment, and Prevention of Tuberculosis. Edited by JOSEPH WALSH, A.M., M.D. Philadelphia: Published by the Henry Phipps Institute. 1909. Pp. 463.

IN this volume is given an account of the general and special clinical and pathological work carried out by members of the staff at the Henry Phipps Institute during the year Feb. 1st, 1907, to Feb. 1st, 1908. In addition to a large mass of statistical information in reference to tuberculosis, several special lines of research are recorded, all of which are of considerable interest. Dr. W. D. Cadbury gives the results of the examination of the bone marrow in cases dying from pulmonary tuberculosis. The study of the marrow was mainly confined to the long bones, although in some cases that of the ribs was examined. The marrow was usually red and soft, and microscopically showed cellular proliferation; a peculiar transformation called mucoid appeared in some of the cases. Proliferated marrow was found most frequently in the femora, and less often in the humeri. In cellular marrow the myelocytes were usually the predominant type of cell; next in numbers came the lymphocytes and polymorphonuclear leucocytes. A few eosinophiles and marrow giant cells were usually found in cellular marrow, together with many nucleated red cells. In about half the cases tubercles were found in the bone marrow, and with especial frequency in the femora. An interesting coloured plate is given, showing the presence of tubercle bacilli in the marrow.

From a clinical point of view a paper by Dr. C. M. Montgomery on Tenderness in Pulmonary Tuberculosis, especially Percussion Tenderness, is of some interest. The author is of opinion that circumscribed tenderness at an apex, especially if it persists, strongly suggests tuberculosis.

Given tenderness at an apex we agree that it is at least necessary to show that the tenderness is not due to tuberculosis. Dr. Montgomery considers that tenderness, especially if marked, is more common over acute lesions, but that it may occur over lesions a long time healed, and that it may be absent over acute lesions even of the pleura. He further points out that circumscribed percussion tenderness in pulmonary tuberculosis usually depends on disease of the pleura or lungs; but, in his view, the tenderness itself may actually reside in the tissues of the chest wall as well as in the pleura itself (or in the tissues immediately external to the pleura), and apparently may occur in normal tissues. While all the tissues of the chest wall down to, and possibly including, the parietal pleura may be tender, the muscles appear more often tender on percussion than the other tissues. This tenderness may be due to a myositis or to neuritis of the nerves in the tender muscles.

A report by Dr. J. Douglas Blackwood upon the opsonic index in pulmonary tuberculosis is inconclusive. An attempt was made by him to regulate the dosage of tuberculin by this means, but as the patients visited the dispensary and were not in-patients, a sufficient number of observations could not be made. The effects of auto-inoculation would also render such tests unreliable.

The present volume contains much that is interesting, and for purposes of reference will prove valuable.

Radium-therapy. By Dr. LOUIS WICKHAM and Dr. DEGRAIS. Translated by S. ERNEST DORE, M.A., M.D. Cantab., M.R.C.P. Lond., with an Introduction by Sir MALCOLM MORRIS, K.C.V.O. London: Cassell and Company, Limited. 1910. Pp. 306. Price 15*s.* net.

IN a previous issue[1] it was our pleasure to make favourable comment on the excellent work in the field of radium-therapy done by Dr. Wickham and M. Degrais, as set forth in the original French edition of their classic volume, while an interesting development in regard to injections of solutions of radium is related by them in a paper at p. 1400 of our present issue. In the book now before us we have all the contents of the original presented to us in our own language, with the additional advantage that the authors have added new facts that have been discovered since the MS. of the original edition was finished in March, 1909. It is thus quite up to date, and will be appreciated by many whose knowledge of the French language is somewhat less than that of their own. The translator is to be congratulated on the excellence of his part of the work. Sir Malcolm Morris has written an introduction in which he pays a well-deserved tribute to the labours of Dr. Wickham, while the latter has provided a preface specially for the English edition. The excellent coloured plates and other illustrations which characterised the French edition are here reproduced in all their good qualities. Being the classic work on the subject, it should be in the hands of those medical men who try to keep pace with modern developments.

Surgical Diagnosis. By ALEXANDER BRYAN JOHNSON, Ph.B., M.D., Professor of Clinical Surgery in the Columbia Medical Schools, Attending Surgeon to the New York Hospital, Visiting Surgeon to the Mount Moriah Hospital, &c. With one coloured plate and 257 illustrations with the pen. London: V. Appleton and Co. 1909. Vol. I., pp. 810; Vol. II., pp. 777; Vol. III., pp. 810. Price £3 15*s.* net.

DIAGNOSIS cannot be learnt from books; it is only in the wards, in the out-patient department, and in the frequent seeing of cases, that the student can learn the most difficult art of diagnosis. Yet, though books cannot serve in the place of clinical experience, they may go far in assisting the student and in making him appreciate the value of the cases he sees. This book is an elaborate treatise devoted mainly to the diagnosis of surgical conditions, for but little is said as to the treatment. The arrangement is mainly regional, the diseases and injuries of the different parts of the body being considered separately, but special chapters are devoted to certain subjects, such as gangrene and gunshot wounds. Many illustrations are given, and in nearly every case they show clearly some morbid condition, though here and there we find some illustrations of but little practical value. A few points have struck us in the work which are, we think, worthy of mention. We are pleased to see that the author ascribes but little importance to the ribbon-like form of the motions in cancer of the rectum. Most of the text-books still state that this is a diagnostic point; we entirely agree with Dr. Johnson that it is a sign of practically no value. We think the three pages and a half devoted to the parathyroid gland are rather a waste of space. In the account of rodent ulcer the author does not seem to be sure in what structure the growth usually arises, though practically all pathologists are agreed that in the vast majority of cases, if not in all, it arises from the cells of the sebaceous glands. The section dealing with the blood in septic diseases is admirable, and indeed all who use the book as an adjunct to the work in the wards and out-patient department will derive much benefit from it.

LIBRARY TABLE.

Botany. By J. REYNOLDS GREEN, Sc.D., F.R.S., Downing College, Cambridge. Illustrated. Pp. 128. Price 1*s.* net. *Biology.* By R. J. HARVEY GIBSON, M.A., Professor of Botany in the University of Liverpool. With numerous illustrations. London: J. M. Dent and Co. 1909. Pp. 120. Price 1*s.* net.—The Science Primers, which were first published 30 years ago by Messrs. Dent and Co., served an excellent purpose in their day. They aimed at representing in simple language and in an elementary or introductory manner the condition of our knowledge of the several sciences at that period. But science has advanced greatly since then; facts have been discovered, observations have been re-interpreted, new theories have been formulated, and old ones amended or discarded altogether. Moreover, research on the border-lines between the various sciences has obliterated the hard-and-fast boundaries at one time supposed to exist, while the vast accessions to knowledge have necessitated extensive subdivisions of many of the sciences. It would seem, therefore, that the time has come when a re-statement of the fundamental theories of the several sciences should be undertaken, more especially in view of the great advances that have been made in recent years in scientific education and of the spread of a desire for knowledge of scientific subjects among the general public. Messrs. Dent are issuing a new series of primers which will be useful for all readers who desire a simple and general, but accurate, knowledge of scientific subjects, and which will afford adequate assistance to primary and secondary teachers who have not been able to make a special study of science at all, or whose knowledge may extend to one or two branches only. In issuing this new series of primers the editor, Dr. J. Reynolds Green, F.R.S., follows out this idea and has secured writers of high rank in science for the first seven volumes, the three volumes dealing with Biology, Botany, and Chemistry being now ready. In the preface to the manual on Botany Dr. Green makes it clear that its object is to present the plant as a living organism, and this has been done most admirably,

[1] THE LANCET, Sept. 25th, 1909, p. 929.

although, perhaps, morphology, with which a beginner more easily becomes acquainted, has been to some extent crowded out by histology. The description of the flower is rather insufficient. The evolution of plants is very well described; a table of stages of development would add to its value by collecting the information. The illustrations are good and well selected. Professor Gibson's volume is a brief sketch of the science of biology and serves as a useful introduction to further studies in the same field. Numerous examples of its processes are given and these are very happily chosen, usually a plant and an animal being considered and contrasted at the same time. The illustrations are clear and sufficient. Altogether the work shows clearly where biology stands at the present time. It is to be regretted that there is no index to either book.

A Winter's Comedy. By HALLIWELL SUTCLIFFE. London: T. Werner Laurie. Pp. 310. Price 6*s.*—In some medical examinations it is the custom to give a "case for diagnosis." In the novel before us Mr. Sutcliffe has given us such a case, and it is this. A young and perfectly healthy woman, except for "a cold," goes hunting on a fine January morning. She and her companion are, together with the huntsman, alone with the hounds. A moorland fog comes down and they wait half an hour. The young woman shivers. The fog lifts and they go to a farm half a mile away. She shivers again and is put to bed. About an hour or two later the medical man who has been summoned arrives, and pronounces his patient to be in a condition which is "grave, of course, very grave." He saw her three times next day, and by 10 o'clock at night was able to say, "with subdued glee, 'She'll live, gentlemen.'" This illness, we learn, is pneumonia, a condition which the medical man diagnoses on his first arrival. And all honour to him, for the rapidity of onset, exacerbation, and resolution in this case, which seems to have been all over in some 30 hours, was remarkable, and might have baffled the highest powers of diagnosis. For the rest we may say that the novel is readable and ends in the orthodox happy manner.

The Birds of the British Islands. By CHARLES STONHAM, C.M.G., F.R.C.S. Eng., F.Z.S. With Illustrations by LILIAN M. MEDLAND. In 20 parts. London: E. Grant Richards. 1909. Price 7*s.* 6*d.* each part.—The sixteenth part of Mr. Stonham's sumptuous history of British birds contains, among others, accounts of the sandpipers, redshanks, and godwits, none of which birds are likely to be familiar to many of our readers. The high standard of the previous issues is well maintained and the illustrations are admirable—indeed, it is wonderful how Miss Medland has managed to make her faithful gradations of light and shade take the place of colour. A particularly full description is given of that interesting bird the ruff, the pugnacious habits of whose males during the pairing season have earned for the genus the name "machetes." "In former times," we are told, "the ruff and reeve bred freely in suitable parts of the eastern counties of England from Northumberland southwards, but now they are, with very rare exceptions, merely spring and autumn visitors on passage." The extinction of the ruff in such counties as Lincolnshire and Norfolk was doubtless due to the drainage and reclamation of the marshlands, and it is sad to know that the improvement of the countryside must lead to a decreasing number of indigenous birds. The ruff, according to Mr. Stonham's interesting account, behaves in his amatory affairs like the typical wicked man in melodrama. He shows extraordinary keenness to obtain possession of the quaintly named female, the reeve, but his object once attained he soon tires of his selected partner and exhibits callous indifference to her charms. The redshank is another bird which used to breed frequently in England, especially in Norfolk, but drainage and reclamation have destroyed the haunts which it most affected. The recurrence of this note of regret for the loss of one more native species causes the suggestion that at the end of his big work Mr. Stonham might well publish a list of the birds which, say 50 years ago, certainly bred in these islands, but which do so no longer; and to this list there might be added another, mentioning the birds which we have gained during the same period.

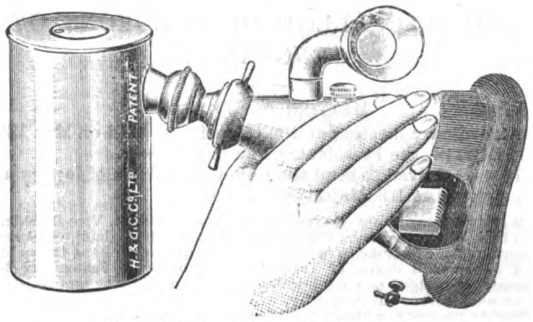
JOURNALS.

The Journal of Physiology. Edited by J. N. LANGLEY, Sc.D., F.R.S. Vol. XL., Nos. 1 and 2. London: C. F. Clay, Cambridge University Press Warehouse. April 26th, 1910. Price 8*s.*—The contents of these numbers are: 1. A Contribution to the Study of Muscle-enzymes, by Fred. Ransom, from the Pharmacological Laboratory, Cambridge. Dr. Ransom's experiments show that it is possible to prepare from frozen muscle a plasma containing a ferment or ferments capable of converting glucose or glycogen into lactic acid, CO_2, and alcohol. The fermentation begins in the case of frog's plasma at once, or at most within ten minutes after the exposure of the preparation to a temperature of from 15° to 32° C. In the case of the fowl plasma there is a delay of less than an hour. By precipitation with alcohol-ethers a powder is obtained from the plasma which acts like the plasma itself, but more slowly. Lactic acid appears to precede the formation of carbon dioxide in the process of fermentation in muscle plasma. 2. On the Exhalation of Drugs by the Lungs, by Arthur R. Cushny, from the Pharmacological Laboratory, University College, London. The conclusions at which the author of this paper arrives are that the exhalation of volatile substances from the lungs is exactly analogous to their evaporation from solutions in water, and the pulmonary cells seem to be purely passive in the process. The amount of any substance which is eliminated by exhalation is dependent, not so much on its volatility as measured by the boiling point, as on its miscibility with water and its chemical affinity with water. The less the solubility and the feebler the affinity the larger the amount exhaled. 3. Flexion Reflex of the Limb, Crossed Extension Reflex, and Reflex Stepping and Standing, by C. S. Sherrington, from the Physiological Laboratory, Liverpool. This is a carefully drawn up account, illustrated by numerous diagrams, of the reflex stimuli and inhibitions of the muscles engaged in standing, stepping, and reflex movements of the limbs in the cat and dog, with and without removal of the brain and division of various nerves. 4. Fatty Acid Metabolism in the Liver: (1) A Method of Fatty Acid Extraction, by V. H. Mottram, Fellow of Trinity College, Cambridge. These numbers also contain the Proceedings of the Physiological Society for Feb. 19th, 1910.

Journal of Anatomy and Physiology. Conducted by Sir WILLIAM TURNER, K.C.B., ALEXANDER MACALISTER, ARTHUR THOMSON, ARTHUR KEITH, and ARTHUR ROBINSON. Vol. XLIV. Third Series. Vol. V., Part III. April, 1910. London: Charles Griffin and Co. Annual subscription £1 1*s.*, post free.—The following articles are contained in this part. 1. Notes on the Development of the Human Sphenoid, by Professor Fawcett of the University of Bristol, with 16 woodcuts. 2. The Architecture of the Cancellous Tissue forming the Upper End of the Femur, by Professor A. Francis Dixon, Trinity College, Dublin, with one plate. 3. The Pituitary Fossa and Certain Skull Measurements, by D. P. Fitzgerald, B.A., M.B. R.U.I., professor of anatomy, University College, Cork. 4. The Arrangement of the Fibres of the Middle Cerebellar Peduncle as shown by Dissection, by E. B. Jamieson, M.D. Edin., lecturer on anatomy, University of Edinburgh, with three excellent figures in the

text showing the disposition of the fibres. 5. Case of an Abnormal Sinuous Aorta, by John L. Annan, M.B. Edin., demonstrator of anatomy, University of Sheffield. 6. Two Cases of Reduplication of the Arteria Cerebri Posterior, by C. Gordon Shaw, M.B., B.S. Melb., senior demonstrator of anatomy in the University of Melbourne. A very rare abnormality of which a woodcut is given. 7. The Presence of Lacrymo-jugal Sutures in Two Human Skulls, by D. G. Reid, M.B. Edin., demonstrator of anatomy in the University of Cambridge. A suture of rare occurrence, only existing in 2 out of 4500 skulls in the Cambridge anatomical department, though common in many animals. When present in man it is always met with in the skulls of the higher races. 8. Description of a new Craniometer and of certain Age-changes in the Anthropoid Skull, by Arthur Keith, M.D. Aberd., F.R.C.S. Eng., conservator of the Museum of the Royal College of Surgeons of England, with nine woodcuts in the text. 9. The Limb Arteries of Primates (Part I.), by T. Manners-Smith, M.A., M.B. Cantab., demonstrator of anatomy in the University of Cambridge, lecturer on anatomy in Downing College, with six plates.

L'Hygiène. Revue Mensuelle Illustrée. Vol. I., Nos. 5 and 6. Paris and London: Goupil et Cie. Price 2 francs 50 centimes.—The April and May numbers of this excellent magazine maintain the position foreshadowed by the earlier issues. The article which perhaps will be read with the greatest interest is one by Dr. George Baudouin, physician to the Hospital Alphen-Salvador, in the April number describing the Association de l'Assistance. This article practically describes the rise of professional nursing in France; and this to a certain extent is a recent story, for the first body having the improvement of nursing as its aim, the Association à Développer et à Perfectionner l'Assistance aux Malades, was not formed until the close of the year 1899. The first installation of the Association de l'Assistance, to abbreviate its title, was in some rooms in the Rue Garancière and dates from January, 1900. This was a school of instruction for nurses and opened with a single pupil, but as the *clientèle* grew larger it became necessary to find new quarters and migration was made to the Rue Amyot, a street in the quarter of Paris behind St. Geneviève. In this building the association has developed its programme, which now, to give a broad translation, is formulated as follows: (1) To furnish for those who can pay competent nurses possessing proper guarantees of character and technical knowledge; and (2) to furnish for the sick poor in their homes or in any institutions gratuitous nursing with similar guarantees. The whole story of the development of the movement is excellently told by Dr. Baudouin, and all interested in the practical side of nursing should read the article. Other communications are a denunciation, strengthened by excellent reproductions of microscope slides, of the household fly by Dr. Vaillard, and a note on the ultra-violet rays in the sterilisation of drinking water by Professor Nogier.



The Burlington Magazine.—The May number of this magazine contains among other things four admirable reproductions of the Budapest Rembrandts. An interesting article entitled "The Educational Aspect of Irish Chippendale" will appeal to collectors, and the same may be said of Ananda K. Coomaraswamy's article on India Bronzes. The illustrations of certain of these bronzes prove their authors to have been aware of the truths of anatomy, but equally alive to the claims of artistic composition. Several of the figures display perfect knowledge of muscular action, although anatomical details are not given; but three or four of them, notably Sundara Murti Swami (Plate 1, Fig. 1) and Pattini Devi (Plate 1, Fig. 5) have a deliberate exaggeration of the slenderness of the waist which shows that the sculptors had their own view as to the necessity of rigid accuracy in ideal representation. But is it not singular that in countries where the corset was unknown the contracted waist should be exhibited as a sign of beauty? With regard to the Rokeby Venus controversy the editors state their belief in the authenticity of the picture to be unshaken.

New Inventions.

APPARATUS FOR THE INHALATION OF ETHER AND OTHER DRUGS.

THIS is an apparatus for the inhalation of ether and other drugs by what is known as the "open method"—i.e., without the patient rebreathing the drugs or his own breath. It consists of a metal drug chamber, a face-piece or mask, and a float (Fig. 1).

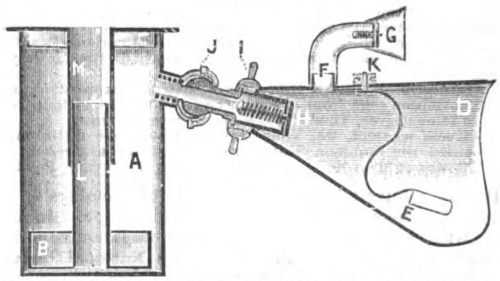


FIG. 1.

The external appearance of the apparatus.

It will be seen that the chamber A, which is cylindrical, has a bottom, and moveable lid, C, with a tube, M, running down from, and fixed to, the inside of the lid C (Fig. 2). This tube, M, is open at both ends, one end communicating through the lid with the external air and the other end being inside the chamber A for the reception of a similar, but smaller, tube L, which is fixed to, and passes through, the middle of a float, B, the rising and falling of which

FIG. 2.

The apparatus in section. A, Drug chamber. B, Float with inner tube. C, Lid with outer tube. D, Face-piece. E, Tongue-piece. F, Outlet funnel. G, Outlet valve. H, Inlet valve. I, Joint for connecting various face-pieces. J, Ball and socket joint. K, Nut for fixing or releasing tongue-piece. L, Inner tube. M, Outer tube.

causes the tubes to work in telescopic fashion. Both tubes being open at both ends causes the air inspired to pass into the chamber through the tubes and to come into contact with the drugs below their surface, from which it emerges into the upper portion of the chamber. The float B is a circular airtight box, the buoyancy of which carries the weight of the smaller tube L to the extent that the upper surface of the box is on a level, or thereabouts, with the surface of the drugs in the chamber.

The chamber has near to the top an outlet valve, H, which permits the air that has passed through the drugs to pass from the chamber A to the face-piece D and thence to the patient, who finally disposes of it by an outlet valve, G, in the funnel, F, from the face-piece. The face-piece D, of the shape ordinarily used for anæsthesia, contains a "perforated tongue" E, which is a piece of metal about 1¼ inches wide, ⅜ inch thick, and ¾ inch deep, and is perforated from back to front to allow the air and drugs to pass from the face-piece into the patient's mouth. This tongue, E, is fastened to the inside of the face-piece by a pliable band and is detachable, K, at will by the person administering the inhalation. The object of the tongue-piece is to prevent the patient closing the teeth while under anæsthesia. The face-piece is connected to the chamber by a ball-and-socket joint, J. The joint I is for connecting various face-pieces.

The makers of the above described apparatus are the Hospitals and General Contracts Company, Mortimer-street, London, W.

ROBERT HUGH HODGSON, M.D. Durh.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

AN ordinary meeting of the Council was held on May 12th, Mr. BUTLIN, the President, being in the chair.

It was resolved to send the following address of loyalty and condolence to His Majesty the King:—

MAY IT PLEASE YOUR MAJESTY,—We, the President, Vice-Presidents and Council of the Royal College of Surgeons of England, venture to approach Your Majesty in order to express our deep grief at the sudden and unexpected death of Your Majesty's beloved Father our late revered Sovereign, and we humbly pray Your Majesty graciously to receive our respectful sympathy.

During his reign, which was all too short, he gained the love and confidence of his subjects throughout the world to a degree which we believe has never been surpassed by any sovereign. At the same time, he endeared himself to the people of foreign countries in a remarkable manner by his tact, courtesy, and kindness, so that his death will be felt by them in little less degree than by his own subjects.

Surely, no Monarch was ever more sincerely mourned than he will be.

We desire respectfully to express our devoted loyalty to Your Majesty, and our trust that God may grant You good health and that Your Majesty may live to reign for many years in the hearts of Your people.

In witness whereof we, Your Majesty's loyal and dutiful subjects, have caused the Common Seal of the College to be hereunto affixed this 12th day of May, 1910. HENRY T. BUTLIN, President.

And it was also resolved to present the following address of condolence to Her Majesty Queen Alexandra:—

MAY IT PLEASE YOUR MAJESTY,—We, the President, Vice-Presidents, and Council of the Royal College of Surgeons of England, desire humbly to offer our sincere and respectful condolence with Your Majesty under the great loss which Your Majesty and Your Illustrious Family have sustained by the sudden and unexpected death of His Majesty King Edward VII.

We earnestly and respectfully trust that the expressions of grief which have been sent from every part of the world will help to mitigate, in some degree, Your Majesty's own private sorrow.

In witness whereof, we, Your Majesty's loyal and dutiful subjects, have caused the Common Seal of the College to be hereunto affixed this 12th day of May, 1910. HENRY T. BUTLIN, President.

It was resolved to grant diplomas of Membership to 88 candidates successful at the recent examination. In accordance with a report from the Court of Examiners it was resolved that the examinations of the National University of Ireland be accepted on the same conditions as the examinations of the late Royal University, so far as candidates are concerned, who desire to enter for the First Professional Examination for the Fellowship. It was resolved to issue diplomas of the Licence of Dental Surgery to 35 successful candidates.

A letter was read from Professor G. A. Wright resigning his seat in the Council, and expressing the wish that the resignation should take effect before the July election. The resignation of Professor Wright was accepted with regret.

A letter was read from Dr. Robert Fletcher expressing his appreciation of the action of the Council in awarding him the College medal, and the PRESIDENT reported that the Right Hon. James Bryce, British Ambassador at Washington, had kindly undertaken to present the medal to Dr. Fletcher on behalf of the College.

MEDICINE AND THE LAW.

The Signing of a Death Certificate by an Unqualified Person.

AT the recent assizes at Leeds, Charlton Forman, who was proved to be in the employment of Mr. Charles Lyddon, a medical practitioner, as a dispenser, bookkeeper, and surgery attendant, was charged with forging that gentleman's name on a certificate of the cause of death. The evidence showed that a little girl who was ill was taken to see the prisoner, who apparently treated her medically, and when she died gave a certificate, to which he appended the name of Mr. Lyddon. Mr. Lyddon, who gave evidence, said that he paid the prisoner not by wages but by a share of profits, and that he himself did not remember ever having seen the deceased. In cross-examination by Mr. H. T. Waddy, counsel for the defence, he said that he had always "told the prisoner to be careful what he was doing," and admitted that he had no idea how many certificates the prisoner might have signed. He stated, however, that he did not know of one certificate being so signed, and denied that his name had often been written on the certificates by the prisoner with his authority. On the other hand, the prisoner admitted having signed many certificates, and stated that he had not been forbidden to do so until Mr. Lyddon received a letter on the subject from the General Medical Council. In the end the jury found the prisoner guilty, but strongly recommended him to lenient treatment, expressing the opinion that the conduct of Mr. Lyddon in the matter should be taken into consideration. Mr. Justice Ridley, who in the course of the trial had made observations on the danger of the practice alleged to have existed, and who in passing sentence expressed the hope that the fact of the prosecution having taken place would have a useful effect, imposed a fine of 40*s*.

The Preservation of Dead Bodies with a View to Identification.

Attention was recently called in THE LANCET to the success which has attended the installation in connexion with the City of London coroner's court of a Herscher's formalin apparatus (Richter's system) for the preservation of dead bodies awaiting identification. At an inquest upon an unknown man which has since been held in that court, Dr. F. J. Waldo elicited from the divisional surgeon of the City Police evidence to the effect that the features had become more recognisable since the body had been subjected to the chemical effect of the formalin. Mr. J. Kearney said that he had noticed this result already in the case of other bodies so treated. In the case in question the photographs of the face of the deceased were found to be much less likely to lead to recognition and positive identification than the inspection of the actual features. The photographs which it is the practice of the City Police to take, in addition to preserving the actual remains, show the full face and profile, and the coroner made the useful suggestion that if others were made to record the appearance of the body in its clothing they would supplement more effectively the means of identification afforded by the formalin apparatus. It was mentioned in the previous note to which we have referred that outside the City the police find descriptions more useful than photographs for the purpose of identification. This may be the case when it is a question of advertising the fact that a body has been found and of inviting those who think that they can recognise it to come forward. For really trustworthy identification the preservation of the body, together with a photographic representation of its appearance when found, must supply the best means, and it is to be regretted that their employment is not more general. Such completeness of identification forms a useful contribution of science to inquiry held in the cause of justice, for both the civil and criminal law are concerned in proof of who the person is who lies dead, and cases will be remembered which have attracted attention where absurd mistakes have been made. Bodies have been claimed by two or more women simultaneously as representing their husbands, and after burial persons "proved" at inquests to be dead have appeared on the scene to show how unsatisfactory their alleged identification has been.

THE LANCET.

LONDON: SATURDAY, MAY 21, 1910.

The Co-education of Men and Women Students of Medicine.

IN the April number of the *London Hospital Gazette* there appeared a suggestion that women medical students should be admitted as students at the London Hospital Medical School and generally to the service of the London Hospital; and in the May number of the same excellent journal several letters are printed on a subject which is of growing importance in education and in hospital administration. The question of the co-education of men and women as medical students has not yet received the close consideration to which it is entitled, but now that the admission of women to the medical profession has long been settled, all the universities and other examining bodies with the exception of the Universities of Oxford and Cambridge having granted to women rights and privileges on exactly the same terms as they grant them to men, the advantages and disadvantages of co-education must receive attention and appreciation. And the matter must be looked at from several sides—we must examine the effect on the hospital as a public charity, on the medical school as a place for the study of men students, and on women medical students as an integral part of the medical profession not yet receiving a full due. The matter would be somewhat more simple as far as London is concerned, if in London there were no medical school admitting women medical students, but there exists the London School of Medicine for Women, where women students have for nearly 40 years been able to study all the subjects of the medical curriculum, and where recently, at great cost, the whole medical school has been modernised. In connexion with the School of Medicine for Women is the Royal Free Hospital, where the greater part of the clinical teaching of the women students is carried on, and they have in the New Hospital for Women further facilities for obtaining clinical instruction, while many of the special hospitals are also open to women medical students. While then certain disabilities do exist for medical women, no one can say that in the last generation things have not moved quickly towards an equalisation of the sexes in the medical profession.

Of the letters which have appeared in the *London Hospital Gazette* by far the most important is one signed "Trotula," the writer being a woman medical student, who has chosen as her pseudonym the name of the well-known woman professor at the celebrated medical school of Salerno. In her letter "Trotula" brings forward a large body of evidence which shows that women students are admitted to medical schools and hospitals on the same terms as men in very many places both abroad and at home. In Paris there are more than 300 women students with some 3000 men students, and the women are permitted to attend all the hospitals. In Rome, Genoa, Bologna, Brussels, Liège, Geneva, and Berne, women students enjoy all the privileges accorded to men, and in some centres this has been the case for many years. In Rome, for instance, women students have been admitted since the year 1870; in Berne they were admitted in 1876. In Upsala and in Copenhagen for more than 30 years the women students have had the same privileges as the men. In the British Isles, since the year 1885, 17 medical schools with the hospitals connected with them have in turn opened their doors to admit women students. In most of the cases all the hospitals of the town where the school is situated have been made available for women students, and in those cases where there are some exceptions it is agreed that the best hospitals have admitted women. The question now naturally arises, What result has the admission of women students had on the entry of men students? Has it had the effect of diminishing the number of those who come as students to the hospitals and medical schools? The answer appears to be unequivocal: no such diminution can be proved from the consideration of the statistics available. Practically in every case there has been on the whole an increase in the number of men students, fluctuations occurring just as occurred before the admission of women. It thus appears to be clear that both at foreign universities and in the medical schools of this country which have tried the experiment of admitting women medical students on the same terms as men, the institutions have not suffered by any diminution in the number of the entries of male students; and if we may reason from these data it may be thought to be fairly sure that this misfortune would not happen if one or more of the medical schools of London were to adopt the same practice. In direct opposition to such apprehensions, it is urged that several advantages would accrue to the hospital if a certain number of women students were admitted every year. The income of the hospital would increase by the amount of the extra fees, and it is further claimed that as the total number of students would be increased the medical school would have greater prestige as a teaching centre. To this it may be answered that an increase in the number of students is by no means an unmixed benefit, for instances have been known where the students have been too numerous for the material which they have opportunity to study. The advantages to the hospital and the existing medical school by the admission of female students cannot be called unequivocal; but the advantages to women medical students would, we think, be certain. The admission to such a hospital as the London Hospital would undoubtedly afford them far greater and more varied clinical experience than can be obtained in a smaller hospital. Here again, however, there is room for reservation. The knowledge of the student depends not so much on the extent of his or her clinical experience as on the use which is made of those facilities which are afforded. We believe that many examiners will agree that some of the best

students, those who diagnose the cases submitted to them most accurately and readily, come from the smaller hospitals. We would not say a word against a large clinical experience, but we believe that any general hospital of even 100 beds is capable of supplying all the clinical experience which the average student needs. The other letters in the *London Hospital Gazette* are a little indefinite in their reasoning, but they leave the reader in no doubt of the views of their writers, who are wholly opposed to the admission of women students. The writers consider that the presence of women would tend to diminish the number of men entering, and they view with apprehension the prospect of a diminution in the number of resident medical appointments available for men.

The questions raised, it will thus be seen, are by no means simple—any curt dismissal of them with a simple yea or nay would be silly. There are, undoubtedly, advantages to medical students in having wider opportunities of study; but, on the other hand, there are no less certain benefits in the practice of women studying medical subjects in a separate school. We do not question for one moment the practicability of mixed classes. Experience of many medical schools both at home and abroad proves conclusively that men and women students can perfectly well work together. In the smaller towns possessing medical schools, where there is not a sufficient number of women wishing to study medicine to justify the establishment of a separate school, it is clearly not unreasonable that the women students should study at the same medical school as the men; but in a city like London, where the number of students of medicine is great, there are surely sufficient women students to justify the carrying on of a separate medical school for their benefit. The difficulties of co-education are in some ways less when we have to deal with clinical instruction, and the really important matter is whether women students have sufficient opportunities in London to study clinical medicine and surgery. We have no doubt that any woman student of medicine can, under existing conditions, find all the opportunities which she really needs for clinical study, and the success of many of them both at examinations and in practice fully bears out this opinion. The tendency of many medical students, both men and women, is to range too widely over the fields of clinical study; rather they should concentrate their attention on a smaller number of cases. A few examples of disease carefully and conscientiously studied will avail far more in examination and in practice than many cases merely glanced at. What the decision of the London Hospital will be we cannot, of course, say, but we feel sure that the care and attention which the importance of the subject demands will be devoted to its consideration. At present we think the suggestion is a little premature, but "Trotula" has raised the issues in an able and ingratiating manner, advancing one argument which will cut the ground away from her most uncompromising opponents. She considers that women students would gain the advantage by training with men students of acquiring a more correct estimate of their own capabilities than could be gained in a medical school where all the students are women.

Freud's Theory of Hysteria and other Psychoneuroses.

THE student of the history of such an old-world disease as hysteria cannot fail to be impressed with the fact that the point of view from which it has been considered has varied greatly from one epoch to another, and that this point of view may be taken to be a reflex of the mental outlook of the age in which it has found an expression. The days of elaboration of comparisons and analogies between hysterical and organic phenomena, such as are associated with the school founded by CHARCOT, have been succeeded by a period when the interpretation of the disease is being sought in the realm of mind, when the symptoms of hysteria are being assigned to a disturbance of a psychological nature that may be traced with precision through all hysterical manifestations. The revolt has been led by BABINSKI, JANET, and FREUD, each of whom has played a noteworthy rôle in the dismemberment of the traditional hysteria. To what extent their somewhat conflicting hypotheses will stand the criticism of subsequent investigation remains to be seen. According to M. BABINSKI, hysteria is a disease by suggestion: only such symptoms as can be produced by suggestion and removed by persuasion can be allowed to be hysterical. If certain symptoms cannot thus be produced or removed, they do not fall into the category of hysteria. While this view has much attractiveness it may be doubted whether the eminent French clinician is not guilty of the logical error of *petitio principii*. His equally eminent compatriot, the learned professor of the Collège de France, has in several contributions of permanent value elaborated a theory of hysteria which is more satisfying and of greater applicability. M. JANET holds that hysteria, almost literally, "is but a sleep and a forgetting," that its keynote is amnesia, the outcome of a dissociation of mental processes and systems which ought normally to be in intimate union. If a patient develops a hysterical monoplegia it is because the system of ideas associated with the voluntary activity of the limb is split off from the general content of consciousness and becomes a disaggregated focus on a lower or subconscious level. Notwithstanding the favourable reception accorded to this hypothesis there are some difficulties in the way of its acceptance.

The views of hysteria and other psychoneuroses associated with the name of Professor SIGMUND FREUD of Vienna are still, we believe, comparatively unknown in this country, although they were promulgated some fifteen years ago and have been both modified and amplified since. They have recently become available to English readers in a translation[1] by Dr. A. A. BRILL, of Columbia University, and this will no doubt serve to give an impetus to their study in England and America. It is a matter of some difficulty to supply a brief analysis of Professor FREUD'S hypothesis without running the risk of misrepresentation, and, as it does not lend itself to cursory summarising, judgment ought not

[1] Selected Papers on Hysteria and Other Psychoneuroses, by Professor Sigmund Freud, Vienna. Translated by A. A. Brill, M.D., Ph.D. New York: The Journal of Nervous and Mental Disease Publishing Company. 1909. Pp. 200. Price $2.00. No. 4 of Nervous and Mental Disease Monograph Series.

to be passed on it prematurely. The claim is rightly made by its author that only those who have attempted to follow in his footsteps by utilising his tests and methods are in a position ultimately to criticise. Professor FREUD'S study has led him to group together hysteria, many phobias and obsessions (usually known as psychasthenia), anxiety neuroses (a form of neurasthenia), and certain hallucinatory psychoses, as "defence psychoneuroses," and in all of these he finds a common factor variously modified, but readily traceable. The prolonged investigation of such cases has convinced him that psychical health existed in all until there appeared some experience, idea, or feeling which evoked so much mental distress or pain that the sufferer decided to forget it and to dismiss it from his mind for ever. That this intentional forgetting succeeds often enough Professor FREUD cannot deny, and he naïvely remarked that he cannot maintain it is pathological. In other persons, however, the effort is a failure, and the unpleasant incident sinks into the mind, but is modified in another way. The unpleasantness—i.e., the "affective" element—is dissociated from the idea, and in the case of hysteria is "converted" or transformed into certain physical manifestations, so that the conscious life is burdened with what may be called a "symbol" of the original "psychical trauma," which has now been consciously forgotten, but which exists "repressed" in the recesses of the subconscious mind. The "symbol," or, in other words, the visible hysterical manifestations, will remain until they are re-converted into the original idea, or rather until the "affective" concomitants of the original idea have been dissociated again from the bodily or physical phenomena and re-transferred to it. This can be done by the "cathartic" or psycho-analytic method, the aim of which is to reconduct these concomitants from the physical to the psychical sphere. If the patient can be made to see, consciously, that the hysterical phenomena of which he complains are the outward, "converted," expression of an unpleasant idea, representing the unpleasant element in it, while the idea itself is quite forgotten, and if he can be led to associate once more the idea and the "affect," then the hysterical phenomena have no longer any *raison d'être*, and disappear. So says the author, and invites us to judge his results. The characteristic feature of hysteria, therefore, according to FREUD, is not amnesia, but the ability of conversion. If the affect of the unbearable idea is converted into physical appearances, hysteria develops. If there is no adaptation for conversion, the affect must remain in the psychical sphere, but becomes attached to other ideas, not in themselves unbearable. These thus develop into obsessions, phobias, anxiety neuroses, and so on. This is Professor FREUD'S psychological theory of the defence psychoneuroses.

There remains to be considered the most important element in it. Of what nature are these unpleasant, unbearable, incidents, feelings, or ideas, that would appear to be so prolific in the establishment of psychical ill-health? In all the cases that Professor FREUD has analysed it has been the sexual life that has furnished the material. Be it hysteria, obsession, phobia, or anxiety neurosis, it matters not; the painful, repressed idea is always and only sexual, according to the Viennese professor. Again he naïvely remarks that it is not possible theoretically to exclude its arising in other spheres; he, however, has not found it so. The reader who has hitherto been unfamiliar with Professor FREUD'S work may be reasonably excused for expressing surprise that every case of hysteria, even in earliest childhood, has for its origin some sexual experience; that acquired anxiety neurosis (a form of neurasthenia, but to be distinguished from it) is the result of coitus interruptus, or of insufficiently gratified libido, or of other sexual factors that need not be specified here; and that very many, if not all, phobias and obsessions have the same etiology. Professor FREUD is candid enough to admit that he cannot deny the occurrence of other causal elements in the development of the defence neuroses, but these pale into insignificance compared with the sexual. If he thinks so, the difficulty of maintaining an open and unbiassed mind in the course of a long and intimate psycho-analysis must be enormous. The temptation to fasten on the most trifling sexual incident must be overwhelming. Wherever one looks for these incidents of the sexual life they can be found near at hand. In fact, Professor FREUD'S hypothesis explains too much. At the same time there is little attempt to deal seriously with those instances of hysteria the etiology of which is palpably not sexual, cases in which cures result without any application of the psycho-analytic method. He admits that this method is inapplicable below a certain *niveau* of intelligence, that he cannot conceive himself entering deeply into the psychic mechanism of a hysteria in a person who appears to him common and disagreeable, and who will not, on closer acquaintanceship, be able to awaken in him human sympathy; that psycho-analysis was created for patients who are permanently incapacitated, but they must possess a certain degree of education and be of reliable character. Thus, on the other hand, his hypothesis explains too little. It may be questioned whether there do not exist certain racial differences of mind, temperament, and disposition whose subtle influence should not be ignored in a consideration of the difficult and important matters to which Professor FREUD has devoted himself for 15 years with rare acumen and untiring energy.

An Interesting Outbreak of Scarlet Fever.

DURING recent years scarlet fever has assumed, in many epidemics, a type so mild that difficulties in diagnosis have frequently arisen. The non-recognition of such mild cases may lead in the future to a marked growth in the prevalence of the disease and to a proportionate increase in the labours of medical officers of health. When the disease is of this exceedingly mild type it is almost impossible to trace the origin of infection or to find "missed" cases; and since medical officers of health up to the present have so efficiently discharged their duties it may happen that when they fail to account for every outbreak that occurs they will unjustly be charged with neglect by a public that cannot appreciate the altered conditions. 20 years ago

scarlet fever was regarded too lightly, but since the Notification of Infectious Diseases Act was adopted the attitude of the public has changed, and the occurrence of a few cases of scarlet fever is often sufficient to engender an unreasoning panic. The right attitude lies between these extremes. Dr. R. SAUNDBY pointed out in our columns recently that a period of exemption from scarlet fever of the malignant type is leading the medical profession to forget the terrors of the disease at the very time when the public fears are exaggerated. Any making light of scarlet fever is to be deprecated, but it may be needful for medical men to point out to their patients that although scarlet fever is a notifiable disease it cannot always be notified, especially when the manifestations are mild.

An outbreak recently occurred at Ingatestone in Essex, which is in many respects interesting in character. The village, which has a population of about 1000, after being practically free from the disease for many years, had the infection introduced, and all the early cases were of so mild a character that they only became recognised when desquamation occurred. A very careful search for missed cases and strict attention to the children attending the public elementary schools appeared to have arrested the spread, when suddenly a series of nine cases occurred. During the next five weeks two or three cases occurred weekly, then suddenly 20 cases occurred in one week, after which the infection rapidly subsided. Milk came under suspicion at the earlier outbreak, and throughout the whole period over 80 per cent. of the houses invaded obtained milk from one source. This in itself was almost sufficient to implicate the milk, but other facts, which the milk theory seems incapable of explaining, had to be taken into consideration. Practically all the cases occurred in a limited area, whereas the milk-supply extended over a much larger area. The largest consumers of milk within the infected area were but little affected, and beyond this area they were not affected at all. All attempts to account for this circumscribed diffusion have so far failed, though apparently every effort has been made to find a satisfactory explanation. Dr. J. C. THRESH, the medical officer to the Essex County Council, in his special report points out many other peculiarities of the outbreak, such as the age and sex incidence, and, notably, the escape of those who drank raw milk, whilst those who only used milk in tea were attacked. The local press have made much of the "mysterious" epidemic, and some appear to think that the two most mysterious features in connexion with the outbreak are the failure of the medical men to diagnose the cases in the early stages, and the failure of the sanitary authority to stamp out the infection. Under conditions such as are described in the report the medical men can be exonerated from all blame; in fact, they are to be highly commended for the way in which they helped the sanitary authority to obtain information about every suspicious case. The authority through its various officers seems to have left no stone unturned to discover the means whereby the infection was being spread and to have taken every possible means to arrest its extension. In this instance, however, the source of origin remains obscure.

Apart from the difficulty of tracing the origin of the outbreak, and of discovering the means of spread, Dr. THRESH'S report brings out clearly the difficulties which the medical practitioner in charge of mild and doubtful cases may have to contend against. If the first case seen is mild and atypical it is very likely to escape recognition and to be classed as influenza, and only later, when some complication such as nephritis occurs, or when desquamation becomes obvious, is its nature established; meanwhile, such a case may easily be the means of spreading the disease widely and the practitioner may be unjustly accused of negligence or incompetence. In the present outbreak about half of the cases were atypical in onset and course, they began often without any definite characteristic commencement of fever, and sometimes failed to manifest any rash, while the appearance of the tongue was rarely characteristic. Cases of sore-throat were very prevalent, and yet patients with this symptom and with coated tongue did not always develop a rash or show peeling subsequently, while those with clean tongues not infrequently desquamated, although no rash was observed. Indeed, Dr. THRESH states that in nearly half of the cases, in the absence of definite scarlet fever in the village, the nature of the infection would not have been suspected. Such cases must present great difficulties to the practitioner even during an epidemic. On the one hand, there is the liability to overlook the true nature of the condition, and thus, in the absence of special precautionary measures, to assist in the spread of the disease. On the other hand, if the case proves not to be scarlet fever, irksome and tedious restrictions are needlessly imposed upon the patient, or he may even be exposed to the risk of infection if he is sent to an isolation hospital. In either case the medical attendant is likely to incur the displeasure of the patient and his relatives, and to suffer unjust condemnation. It is hard for the lay mind to grasp the fact that even common diseases are variable in their manifestations, that they are, indeed, morbid states and not stereotyped entities. Even when a rash is present the diagnosis of scarlet fever may present difficulties, owing to the other rashes which may simulate its characters. In the absence of a rash and of a typical onset the recognition of the disease may be wellnigh impossible until some complication arises or until desquamation occurs; moreover, even desquamation may be inconclusive, since it is not infrequent in other conditions. It is important that these facts should be more widely known, since they would lead to a due appreciation of the difficulties which the health authorities and the medical practitioners both have to face in their respective spheres of duty. The practitioner has responsibilities in regard to the public health as well as to his individual patients, and these he is bound to discharge under penalty. It ought to be more generally recognised that in the care of patients with doubtful infectious disease the medical man has a very difficult task.

BRITISH MEDICAL BENEVOLENT FUND GUILD.—A drawing-room meeting of the Guild will be held on Wednesday, May 25th, at 19, Portland-place, London, W., by the kind permission of Lady Fripp.

Annotations.

"Ne quid nimis."

WHOOPING-COUGH MORTALITY.

ONE of the most important and satisfactory features of the remarkable and continuous decline of the death-rate in England and Wales during the last 50 years, and more especially during the current decennium, is the fact that the proportional decline of child mortality has exceeded the decline at all ages of the population. The last published report of the Registrar-General shows that the mean annual crude death-rate in England and Wales during the 10 years 1861–70 was equal to 21·3 per 1000 of the population at all ages, since which it has steadily declined, and did not exceed 15·6 per 1000 during the eight years 1901–08, thus showing a decline in the rate of mortality equal to 27 per cent. Among children aged under 5 years the mean annual rate of mortality was equal to 68·6 per 1000 during the ten years 1861–70, and had declined to 46·7 per 1000 during the eight years 1901–08, the decline of mortality at these ages being equal to 32 per cent., against 27 per cent. at all ages. This marked decline of child mortality invests with much interest the statistics of whooping-cough mortality, which is more essentially a child mortality than any other of the principal epidemic diseases, not even excepting measles. Of the 9851 deaths from whooping-cough registered in England and Wales during 1908, the most recent year for which the facts are yet available, 97 per cent. were of children under the age of 5 years, and 2·7 per cent. of children aged between 5 and 10 years, only 26 of the 9851 deaths from this disease during the year being of persons aged upwards of 10 years. It may be noted that of the 8011 fatal cases of measles in England and Wales during 1908, 93 per cent. were of children under 5 years of age. During the 10 years 1861–70 the mean annual rate of mortality from whooping-cough was equal to 530 per 1,000,000 of the population of England and Wales at all ages, and successively declined to 513, 451, and 378 per 1,000,000 in the three following decennia; the mean annual death-rate from this disease further declined to 289 per 1,000,000 during the first eight years (1901–08) of the current decennium. Thus the mean annual crude death-rate from whooping-cough during these eight years showed a decline of no less than 45 per cent. from the rate that prevailed in the 10 years 1861–70, whereas the decline in the mortality of children under 5 years, from all causes, during the same period did not exceed 32 per cent. The decline in the death-rate from whooping-cough, calculated on the population at all ages, must, however, somewhat overstate the true rate of decline, as the English population at the present time includes a considerably smaller proportion of children under 10 years of age than was the case 40 or 50 years ago; and we have seen that whooping-cough is a disease almost exclusively fatal among children under the age of 10 years. Whooping-cough appears to be the only one of the principal epidemic diseases of which the mortality among female children is persistently higher than among male children. The mean annual mortality from this disease during the eight years 1901–08 was equal to 289 per 1,000,000 persons of all ages and of both sexes, as stated above; among males, however, the mean rate did not exceed 268, while it was equal to 309 per 1,000,000 among females. There is one other exceptional feature of whooping-cough mortality which is worthy of note. It appears from a table in the Registrar-General's annual report for 1908 that the death-rate from whooping-cough among infants under one year of age in rural populations exceeds that in urban populations. The ratio of urban to rural mortality (under one year) from whooping-cough is stated to be as 85 to 100, whereas the mortality from other epidemic diseases is almost invariably considerably higher in urban than in rural populations. That the present proportional mortality among cases of whooping-cough is in great measure the result of ignorance and the neglect of due care and treatment is fully proved by such class-mortality statistics as have been hitherto published. The fact, moreover, that the mean annual rate of mortality from scarlet fever in England and Wales, which in the 10 years 1861–70 was equal to 971 per 1,000,000, whereas it did not exceed 113 per 1,000,000 in the eight years 1901–08, showing a decline of 88 per cent., suggests for consideration the sanitary problem whether hospital treatment of whooping-cough and measles might not very sensibly accelerate the decline of child mortality, which is already one of the most encouraging results of our improved sanitary system of administration.

A BIOGRAPHER OF MOLIÈRE.

BY the death of Alexander Menzies Brown, sometime officer of health in Sydney, New South Wales, the honourable little company of medical men of letters and medical antiquarians loses one of its oldest and most cultivated personalities. An omnivorous reader and systematic student of French literature and philosophy in the seventeenth and eighteenth centuries, Dr. Brown will be chiefly remembered for his book on "Molière and his Medical Associations," which was discussed in complimentary terms by ourselves on its appearance. In this charmingly written work the writer accounts for the great French comic writer's contempt for doctors on the ground that Molière was himself ill of a disease which, when far advanced, is still for the most part incurable even by the most enlightened physicians. Molière was phthisical, and the rudimentary seventeenth century medicine could not help him, and so Molière hated medicine. Even in these days we come across hatred and satire thus actuated. "But for his bodily infirmities, as well as those of his mind," says Dr. Brown, "he found artistic uses. The cough he had been subject to for so many years became a feature in his style, and gave a pleasing and peculiar force to certain of his rôles. Molière's cough, like the lameness of Béjart, his fellow actor, was for a long time a tradition of the Parisian stage." He died in harness and in a strangely characteristic part. "On the evening of February 17th, 1673, in performing Argan in the *Malade Imaginaire*, towards the conclusion of the piece, and at the moment of pronouncing the immortal *Juro!* he was seized with a fatal illness; he tried to hide his feelings in his wonted laugh," the curtain fell, and in an hour he was dead. But, characteristically, during that hour he managed to abuse his wife's soup, and to refuse medicine—("Why should I lose the little that remains of life?")—while asking for a pillow "stuffed with drugs," which his wife had promised him to make him sleep. With his last words almost he declared that his hæmorrhage was no worse than usual. Molière's medical biographer has himself ended in a manner remarkable from the point of view of both medicine and literature. Ill, and often very seriously ill, for many years of a long life from the after-effects of malaria, which he could not shake off, Dr. Brown was apt to say sarcastic things about the powerlessness of medicine even in the present age. In a letter to a friend he has described his last illness and his own end in a manner and with a fortitude which compel admiration for his training as a medical man. The recipient of the letter does not feel that he is guilty of any breach

of confidence in reprinting some portions of Dr. Brown's letter, which was written to dictation a fortnight before death. Dr. Brown fell very ill in November last, when, as he says, "Profuse cold perspiration and exhausting cough led to asthmatic spasms and unconsciousness. My medical attendant and a near relative were summoned and last instructions given. ..... Hovering between life and death till the night of the 29th, a change for the worse occurred and all seemed up with me. Calmly contemplating the painless ebbing process of my long and feverish life, I marked the doctor's pose sitting on the bedside nursing his knee familiarly, looking at my face and the almost pulseless wrist he had just been feeling. With a dubious expression he broke silence with the cool remark, 'Well, my friend, how do you feel in mind?' 'Resigned,' was the reply and as audibly as strength permitted. Apologies to Swinburne—

> 'The weakest stand, the strongest fall:
> Four score years, no hope, no fear;
> The poppied sleep the end of all.'

The impression [elicited by my remark] was a smile of sympathy and a movement of the lips suggestive of Amen! Nothing more. But the end was not yet." This letter is a remarkable document, an instance of that *æquanimitas* to which we all hope to attain at the last. It is not often, indeed, that a man has the courage to describe what he has believed to be his own last moments. Of Dr. Brown's contributions to medical literature his treatise on the "Animal Alkaloids" reached its third edition in 1894, but his scientific culture was not properly of this age. We prefer to remember him in connexion with the name of Molière and as himself the grandson of a Brown who was an intimate friend of the young Robert Burns.

MULTIPLE PHLEBITIS IN SECONDARY SYPHILIS: PRESENCE OF THE SPIROCHÆTA IN THE WALL OF THE VEINS.

AT a meeting of the Société Médicale des Hôpitaux of Paris on April 8th M. Georges Thibierge and M. Paul Ravaut reported a case of secondary syphilis in which occurred a lesion which is insufficiently recognised, though many cases have now been observed—multiple phlebitis. It presents well-marked characteristics; it affects the superficial veins of the limbs, usually of several limbs; there is only slight inflammatory reaction; embolism never occurs; and resolution is slow. The case now reported derives additional interest from the fact that the spirochæta pallida was demonstrated in the walls of the affected veins. A man, aged 25 years, suffering from secondary syphilis, was admitted into hospital on Feb. 25th last. He contracted the disease in the previous December. There was an abundant papular eruption. On March 7th, while his legs were being palpated to ascertain the degree of infiltration of the syphilides, a hard, slightly painful cord of the size of a goose-quill was found in the position of the internal saphenous vein in the lower two-thirds of the right thigh. There was neither redness nor œdema of the limb. The patient declared that for two days he had felt slight pain in the right leg. On the inner side of the leg several hard cords were found, presenting the same characters as the cord in the thigh. In the left leg a similar cord was found, although no pain was felt. On March 8th 5 centimetres of the right internal saphenous vein were removed between two ligatures. On the following days the lesions in the left leg and the left internal saphenous vein, which was neither painful nor tender, formed in the calf a "pipe tube," which was prolonged into the thigh. There was no fever; the patient was only a little weak. On March 21st similar lesions were beginning in the anterior part of the left forearm. On the 26th slight pain was felt in the right elbow and arm. On the following days more veins became affected in the forearms. The excised fragment of vein was found almost completely occluded and a trace of its lumen was found in the centre with difficulty. It contained neither clot nor liquid blood, but only some serous fluid. Examination of smears made from the internal coat of the vein under the ultra-microscope showed amid cellular débris five spirochætæ pallidæ, of which two showed movements. The occlusion and induration of the vein were due to proliferation of the internal coat which formed a series of large prominences budding into the lumen of the vein. At certain places these prominences showed traces of old hæmorrhages. From the excised vein a monkey was inoculated and lesions characteristic of syphilis were produced.

THE USE OF EAU-DE-VIE IN CONNEXION WITH THE PREVALENCE OF TUBERCULOSIS.

Dr. Jacques Bertillon, before the Statistical Society of Paris, has recently compared two maps of France, on one of which were graphically represented the consumption of *eau-de-vie* in each department, and on the other the prevalence of pulmonary phthisis. The first map demonstrated the consumption of *eau-de-vie* to be much greater in the north than in the centre or the south of France; in other words, that there is much less *eau-de-vie* drunk in the wine districts than elsewhere. The second map had a curious correspondence with the first, inasmuch as more phthisis appears to have been certified in the north and east than in the centre and south. The relation indicated between the consumption of *eau-de-vie* and the prevalence of phthisis was also supported by figures having reference to occupation which M. Bertillon brought forward. Thus he found that the mortality from phthisis among *cabaretiers* was much greater than that among shopkeepers leading otherwise the same existence, while railway workmen, with whom sobriety is compulsory, do not suffer from phthisis to anything like the extent which the carmen, draymen, and cabmen suffer. The sex distribution of phthisis, according to M. Bertillon, tells the same story, the attack-rate among adult males being much higher than that among adult females, though in youth the figures are the same; and it is the men, he says, who are mainly responsible for the consumption of alcohol in big cities. From these considerations M. Bertillon came to the conclusion that the first step in the crusade against tuberculosis is to limit the consumption of *eau-de-vie*. To do this, he thinks, would be more efficacious in abating the prevalence of phthisis than either the construction of sanatoriums or the demolition of insanitary buildings, in which connexion he referred, we presume, to the proposal of M. Juillerat, the well-known chief of the Hygienic Bureau of the city of Paris, for dealing with the foci of tuberculosis in the French capital.[1] M. Bertillon's views did not escape criticism. M. Vassilière suggested that the partition of France into the north, central, and south districts did not take into account the fact that the working classes of the south of France drank vast quantities of liquid alcohol, notably absinthe, apparently without the number of cases of tuberculosis increasing. He said also that the districts of the north and east have dense populations living in unhygienic conditions; and he pointed out that in the *corons* (groups of dwellings constructed by the coal-mining companies for their employees) the miners, though they were formidable consumers of alcohol, had a much smaller attack-rate of tuberculosis than the workmen in towns. He considered that the influence of alcohol on

[1] See THE LANCET, Jan. 1st, 1910, p. 35.

the prevalence of phthisis must be studied in connexion with the influences of unhygienic conditions, density of population, and so on. M. Bertillon explained that he had excluded from his actual map with reference to phthisis the towns, and had not taken the influence of absinthe into account because there were no official figures forthcoming. M. Schelle and M. Cadoux both pointed out that the influence of climate must be taken into consideration. M. Bernard agreed with M. Bertillon's arguments as far as they had reference to railway employees, pointing out that among engine-drivers, with whom sobriety is compulsory, phthisis is very rare, while the lower class of porters suffer from phthisis and drink freely. An interesting debate was left, it will be seen, in a rather inconclusive position. The suggestion of a connexion between the abuse of alcohol and the prevalence of phthisis, as indicated by the maps, was admitted by the audience, and in this way the etiological importance of alcoholism in phthisis has gained support; but it seems clear that M. Bertillon did not carry his audience with him in attributing the first rôle in causation to alcoholism. The general result of previous statistical inquiry has proved the proneness to phthisis of those who live under bad social conditions, in poorly ventilated and ill-lighted rooms, and under conditions of overcrowding and uncleanliness; and M. Bertillon's arguments leave the accepted conclusions untouched.

CHRONIC PURPURA DUE TO MALIGNANT ENDOCARDITIS.

IN the *British Journal of Dermatology* for February Dr. F. Parkes Weber has reported a case of chronic purpura due to malignant endocarditis which simulated splenic anæmia. A sailor, aged 28 years, was admitted into hospital on July 1st, 1909. At the age of 20 years and also at the age of 21 years he suffered from gonorrhœa; at the age of 24 years he had malaria. His present illness began two years before admission with purpuric spots on the legs. He gradually became weaker and paler, and noticed an increasing swelling on the left side of the abdomen. There were occasional oozing of blood from the gums and slight epistaxis. He was treated at several London hospitals apparently under the diagnosis of splenic anæmia. On admission he was very pale, weak, and wasted. The legs and lower and inner aspects of the thighs were covered with spots of brown pigmentation between which were petechiæ. On the arms and trunk were a few petechiæ. The ankles were œdematous. There was tendency to bleed from the gums. The heart was somewhat enlarged, the apex beat was in the fifth space outside the nipple line, and there was a systolic apical murmur. A few dry bronchitic sounds were heard. The spleen was greatly enlarged and hard; it reached to the umbilicus on the right and downwards into the inguinal region. The liver was enlarged and hard and its lower edge was felt at the level of the umbilicus. There were a few retinal hæmorrhages and some conjunctival petechiæ. The urine contained a little albumin and some granular and epithelial casts, and afterwards some blood casts. There was no evidence of active malaria. Blood examination showed 1,700,000 red corpuscles, 1900 leucocytes, hæmoglobin 30 per cent., and colour index 0·9. A differential count gave: neutrophile polymorphonuclears, 63·5 per cent; lymphocytes, 29·5 per cent.; intermediates, 4 per cent.; large hyalines, 2·5 per cent.; and mast cells, 0·5 per cent. Dr. Weber accepted the diagnosis of splenic anæmia and gave arsenic. For the first ten days the temperature was often raised to about 101° F., but afterwards there was seldom any fever. Death occurred on July 29th. Towards the end there were considerable bronchitic signs and œdema. At the necropsy the heart was found large and weighed 21 ounces. The left ventricle was hypertrophied. The musculature was very pale. There was old thickening of the mitral valve to which was adherent a soft organised thrombus. In the left auricle a large polypoid excrescence grew from the septum; it was evidently an organised thrombus. At the bases of the lungs were some bright red pleural petechiæ. There was some serous effusion into the left pleura, and also some ascites. The spleen was very large, weighing 110 ounces. It showed several subcapsular anæmic infarcts, some of which were surrounded by perisplenitic adhesions. On section the spleen had a milky-red appearance. The liver was large and weighed 156 ounces, and there were some perihepatic adhesions. The kidneys were large and pale. In the right kidney was an infarct. There were petechiæ on the mucous membrane of the stomach and intestines. The bone marrow of the left humerus was examined and found quite red. Microscopic examination of the spleen showed some fibrosis and large numbers of plasma cells, mainly in rows or small groups near the larger trabeculæ and follicular arteries. The polynuclears in the pulp were much increased. In the liver there were cellular infiltrates in the portal spaces. The bone marrow was extremely cellular and the fat elements had disappeared. The cells were mostly plasma cells with small and large lymphocyte forms. It is remarkable that chronic purpura of two years' duration was due to malignant endocarditis, and that there were leucopenia and splenomegaly which seemed to point to splenic anæmia. Dr. Weber suggests that "splenic anæmia" may be nothing more than a group of symptoms the result of various pathological conditions. In many cases the necropsy has shown considerable vascular or endocardial disease, probably of infectious origin. In a case published by Dr. S. West there was evidence of considerable old disease of the aortic valves, and septic pyrexia occurred at the end. Also in several cases of "splenic anæmia" thrombotic obstruction of the splenic and portal veins or disease of the splenic artery has been found.

SEROTHERAPY IN RHEUMATIC AFFECTIONS OF THE EYE.

Dr. Deschamps of Grenoble, in the last issue of *La Clinique Ophtalmologique* (May 10th, 1910), remarks that until quite recently the bacteriology of rheumatism and its serotherapy have been very obscure, but that since the remarkable report presented by G. Rosenthal to the congress at Budapest last year the subject has entered into a new phase. The bacillus of Achalme, which has been recognised for about ten years, appears to him to constitute the pathogenic agent of rheumatism. The description of this bacillus, as given by Berlioz,[1] is that it is of large size and resembles the bacillus of charbon, having a length of 5 to 7 μ and a breadth of about 1 μ. It is motionless, easily stains, taking both the Gram and the Claudius stain. It is anaerobic. To cultivate it Rosenthal employs his sealed tube, which consists of a layer of lanoline 2 inches high superposed on the culture liquid. This may be ordinary broth, but by preference milk. The milk coagulates in the course of 24 hours with formation and escape of gas. The bacillus survives for several months in the milk. A few fragments of white of egg introduced into the milk cause the bacilli to sporulate. In 1908 Thiroloix found on experimenting upon rabbits, pigs, and calves, that this bacillus produced typical polyarthritis with endocarditis and pericarditis; and in 1909 the same observer, in conjunction with Mdlle. Zoffé and

[1] Dauphiné Médical, No. 5, 1909.

Dr. Rosenthal, isolated it from the blood of several patients suffering from rheumatic affections by means of hæmobioculture. Rosenthal prepared from the serum of horses that had been rendered immune an antirheumatic serum. Dr. Berlioz treated with it various cases with success, whereupon Dr. Deschamps determned to test its value on some examples of rheumatic iritis, and he proceeds to record in detail various cases, amongst which are several of severe iritis of a rheumatic type, which were greatly benefited by this mode of treatment.

A MEDICAL MISSION IN MANCHESTER.

IN a part of Manchester called Red Bank, where the dwellers are very poor indeed, a philanthropic medical man, many years ago, started a medical mission. Red Bank was what is called a low neighbourhood, and besides feeling the burden of bodily sickness, so common in such regions, Mr. Meacham, a good man, was grieved by the godless ignorance of the people. His dispensary was soon crowded with patients, and through his efforts to help in restoring their physical health he hoped to influence for good their moral and religious condition. He has been dead some years, but the institution he founded is still in existence, and the work is carried on by Dr. R. M. Fenn; and now, like many charities, it needs help. At the annual meeting on May 5th, held in the Mayor's Parlour, the treasurer, Mr. A. T. Arthur, said that if it were not better supported it would have to close its doors. There is a deficiency on last year's working, together with an adverse balance brought from the previous year, amounting to £310. The Lady Mayoress said that as the result of a recent visit she had formed the impression "that an absolutely necessary work was being done," and that many helped by the mission would not like to go to the Royal Infirmary. Last year 1290 people were treated, involving 9250 attendances. Of course, all this work ought not to be required, it is contrary to all proper ideas of political economy, but the sickness and distress are there, and until present conditions have ceased it would be inhuman to do nothing in relief. Mr. T. Crewdson said that £200 a year additional would go a long way to put them right financially. Surely a great city like Manchester can raise that amount each year. Medical missions, if worked on a proper basis, and if care is taken not to deprive practitioners in the neighbourhood of a hard-earned wage, undoubtedly do an immense amount of good. The east and the south parts of London bear witness to this, and London is so huge and so disorganised, or rather unorganised, that what can be done for good in that congeries of towns should not be impossible for a self-contained city like Manchester.

ATROPINE IN THE TREATMENT OF TETANUS.

EVEN with the assistance of the antitetanic serum the treatment of tetanus cannot be described as very satisfactory, because deaths occur in spite of all treatment. We have received from Dr. R. F. Secoresto of Barbados an account of two cases of tetanus in which he employed atropine in the treatment. The first case was a coloured boy, 14 years old. Eight days previously he had received a wound in the foot, and four days later the first spasm had occurred. He received medical treatment, but grew worse, and Dr. Secoresto saw him, as already mentioned, eight days after the injury. Well-marked trismus was present, and apparently the whole of the body was involved in the tetanic spasm. The prognosis was very unfavourable on account of the severity of the symptoms. Dr. Secoresto gave by the mouth an eighth of a grain of morphine combined with 1-300th of a grain of atropine every two hours for three doses and then every four hours. From the first dose the spasms markedly decreased in frequency and severity, and the patient was able to obtain good rest at night. In about four weeks the patient was up and about the house. In addition, small doses of calomel and sodium sulphate were given to keep the bowels open, and the wound was dressed with hot turpentine. The second case was a coloured boy, three years old, whom Dr. Secoresto saw by accident, when a well-marked trismus was noticed, but no wound could be found. He had stiffness of the muscles of the body. He was treated similarly, but with smaller doses, and by the beginning of the fourth week all symptoms had disappeared. Dr. Secoresto has seen many cases of tetanus, and was surprised at the effect of the treatment. He mentions as confirmatory of the use of atropine in tetanus that the Government veterinary surgeon told him that he employed large doses of belladonna with small doses of morphia in treatment of tetanus in animals, and that a fatal result rarely occurred. The use of belladonna and of its alkaloid atropine is not by any means new in the treatment of tetanus, but its administration has been abandoned for the most part. It is possible that the employment of the alkaloid may be more satisfactory than the drug itself, and at all events atropine is deserving of trial in cases not responding to the serum treatment. The experience of anyone like Dr. Secoresto, who has seen a great deal of the disease, is always of value, but more than two cases would be needed to place the value of belladonna and atropine beyond dispute in the treatment of tetanus.

SUDDEN WHITENING OF THE HAIR.

SUDDEN whitening of the hair as a result of fright, emotion, or shock figures more frequently in fiction than in the actual records of medical experience, though it is probable that most people believe in the possibility of its occurrence. Professor L. Stieda of Königsberg reviews the subject of the mechanism by which under ordinary conditions hair turns grey or white in an interesting paper in the *Wiener Medicinische Wochenschrift* of March 26th, and he comes to the conclusion that no case of sudden blanching of the hair has ever been satisfactorily established; and, indeed, he goes so far as to suggest that no case has ever occurred or ever will occur. The basis of his negation is that he finds that in the ordinary or physiological whitening of the hair the change is not due to an alteration or a disappearance of the pigment of the hair, but to a replacement of a dark or coloured hair by a clear hair free from pigment. The process is therefore a change of hair (Haarwechsel) and not a depigmentation. The natural colour of hair depends upon the occurrence within it of pigment, and if this is wanting the hair appears grey or white, but the presence of air within the hair may also contribute to its white or grey appearance. Pigmented hairs may contain their colouring matter in granular form or diffused. Light brown, blond, and red hairs appear under the microscope as if saturated. The cortical substance is uniformly coloured, the medullary part is free from pigment. On the other hand, dark and black hairs contain their pigment in fine granules or in large masses, the pigment being so thick in black hairs that no details of the structure can be distinguished, but even in these hairs in the human subject the medulla of the hair is pigment-free. The pigment, according to Professor Stieda, is extraordinarily resistant, and he states that in Egyptian mummies and in bodies which have been in the earth for long periods it is still distinguishable. In regard to the development of pigment in hairs Professor Stieda supports the view of Schwalbe and Meirowski that it develops in the hair cells themselves, and he opposes the older view that the pigment is brought to the cells by pigmented connective cells. Any

alteration in the colour of the hair occurring normally is attributed to falling out of the hair and replacement by hair of another colour or by grey hair. At the same time Professor Stieda admits that a pigmented hair may become grey in its proximal part if the development of pigment in the hair root ceases, so that the newly formed part of a pigmented hair may thus become colourless. The whitening of the hair associated with advancing years is regarded as a physiological process, but Professor Stieda allows that psychical agencies, such as long grief, anxiety, and insanity, may induce similar changes, which are, however, not necessarily permanent. The average life of the hairs is a matter of considerable importance in regard to this question. According to the observations of Dr. Pincus of Berlin, the long hairs of the head last from two to four years, the short ones from four to nine months. Dr. Moll has calculated that the life of the eyelashes is from three to four months. Various theories have been put forward to explain the supposed occurrence of sudden whitening of the hair. Vauquelin suggested that a substance might be excreted by the skin powerful enough to destroy the pigment of the hair. Another suggestion, proposed by Landois, was to the effect that a sudden accumulation of air occurred within the hairs. Metchnikoff has supposed that certain phagocytes or chromophages enter the hair and withdraw its pigment. All of these suggestions Professor Stieda subjects to a very destructive criticism, and he concludes by affirming that all the supposed cases of sudden blanching of the hair are either instances of deception or of incorrect observation. He gives several instances in point; among them the historical example of Marie Antoinette, whose hair is said to have turned grey the night before her execution, the fact being that she had been greyhaired for some time previously. He also mentions the case of a medical practitioner with dark hair in Berlin who went into a hospital to undergo an operation. On leaving he was much commiserated by many people owing to the fact that his hair was snow-white. The truth, however, was that he was not able to dye his hair as he had previously done daily, an explanation which he appears to have withheld from his sympathisers.

THE BRITISH HOSPITALS ASSOCIATION.

A MEETING of this association, which was originally founded in 1884, was recently held at Guy's Hospital by permission of the treasurer and house committee, Mr. H. Cosmo Bonsor being in the chair. The objects of the association are (1) to facilitate the consideration and discussion of matters connected with hospital management, and, where advisable, to take measures to further the decisions arrived at; and (2) to afford opportunities for the acquisition of a knowledge of hospital administration, both lay and medical. The association also proposes to arrange for the reading, discussion, and publication of approved papers; for the delivery of lectures; and for the holding of an annual conference for the consideration of matters relating to hospital administration and construction, hospital management, medical relief, medical education in relation to hospitals, provident dispensaries, the Poor-law, and other kindred subjects. The membership of the association is active and honorary. Active members are those who at the time of their election are trustees, members of committee or executive, and professional heads of hospitals, without reference to sex or title. All applications for membership should be in writing and addressed to one of the secretaries. The executive officers of the association are the president, vice-presidents, secretaries, treasurer, and members of the council. The following officers were elected at the meeting:—President: Mr. H. Cosmo Bonsor, treasurer of Guy's Hospital. Treasurer: Mr. Conrad W. Thies, secretary of the Royal Free Hospital. Honorary secretaries: Dr. D. J. Mackintosh, the superintendent of the Western Infirmary, Glasgow; and Mr. William West, treasurer and chairman of St. George's Hospital. The council includes members from London, from the provinces, and from Scotland. Applications for membership are to be made to either of the honorary secretaries—to Dr. Mackintosh, at the Western Infirmary, Glasgow, or to Mr. West, at 3A, Lyall-street, Belgrave-square, London, S.W.

VASO-MOTOR AND OTHER PHENOMENA ASSOCIATED WITH CERVICAL RIB.

IN the paragraph on angio-neurotic œdema in his well-known text-book of medicine Professor Osler referred to the case of a man whose whole arm became swollen on exertion. In default of a more definite explanation it was at the time relegated to the group of angio-neuroses. Now, however, a case closely similar in essential features has come under Professor Osler's observation (which is published in the *American Journal of Medical Sciences* for April) and he has been able to refer the paroxysmal phenomena to the presence of a cervical rib. The patient, a woman aged 31 years, whose general health was irreproachable, found that after using her left arm for a while it became red and numb, and it felt swollen and hot, occasionally with a sensation of pins and needles. In the end it would become useless. When at rest the arm was natural, and work done with the fingers alone was quite free from uncomfortable results. The attacks were getting worse, and in an unusually severe one she had fainted. There was a pulsation above each clavicle which was certainly arterial, and more forcible on the left side. On deep pressure a firm resistance was encountered. The arm was free from muscular wasting and objective sensory disturbance. In a skiagram a cervical rib was discoverable on either side, that on the right being the larger. Cases of cervical rib have been reported in which the forearm became livid and swollen as the other symptoms progressed, and the explanation advanced for such phenomena throws light on the case of Professor Osler's patient. It is suggested that compression of the subclavian artery between the cervical rib and the scalenus anticus muscle permitted enough blood to pass through to the arm in ordinary circumstances, but that the extra demand created by muscular exertion could not be met owing to the arterial obstruction, the result being the phenomena detailed above. As Professor Osler remarks, there is an interesting analogy between the condition and that of intermittent limp. In his paper a third case is referred to, in which the presence or absence of cervical rib was not determined; but so close is the similarity between the symptoms in this case and those of the patient more recently under observation, that both are almost certainly susceptible of one and the same interpretation, as well, of course, as the case alluded to in Professor Osler's text-book.

MEDICAL INSPECTION OF INSTITUTIONS FOR CHILDREN.

THE National League for Physical Education and Improvement, which did good work in relation to the passage of the Act enforcing medical inspection of school children, has recently turned its attention to a kindred subject—that of the medical supervision of children in orphanages and in homes for the blind, deaf, and otherwise afflicted. With this object it addressed a series of questions to all known institutions of the kind which had accommodation for 40 inmates and upwards, and the answers obtained are summarised in a report which has been issued by the council of the league. It is to be regretted that of 135 institutions to which questions were sent only 47 sent replies, though even thus information is supplied as to a

population of over 13,000 children. How far the inclusion of data from the remaining homes would have modified the statistics obtained it is impossible to say, but it is natural to suppose that those institutions which were best organised with respect to medical supervision would answer, while those whose arrangements were less creditable would maintain a discreet silence. Hence there is some reason to fear that reliance on the figures given in the report may lead to unduly optimistic conclusions. Even so, the council of the league is driven to the conclusion that the existing arrangements are inadequate, especially among the smaller homes. The actual figures show that of the 47 institutions which sent replies, 38, or 80·8 per cent., had salaried or honorary medical officers on their staffs, and that in 17, or 36·1 per cent., provision was made for periodical inspection apart from actual recognised illness, these latter homes containing altogether 9869 children, or over two-thirds of all those dealt with in the report. In 41 homes medical examination of the children with respect to diseases of the eye, ear, nose, throat, and teeth is carried out on admission. Records of the physical development of the children are not kept as they should be, rather less than half the institutions keeping a register of weight, and other features being even less regularly noted. One institution has its own sanatorium for incipient tuberculous patients, with an open-air school, and another has a country branch for delicate children. The whole report throws valuable light upon a matter of considerable importance, which seems hitherto to have escaped public attention, and we welcome the action of the league in instituting the inquiry. Now that the question has been raised, we hope it may be found possible to elucidate the degree of medical care under which the children live in those institutions which have not replied to the circular.

IN consequence of the death of His Majesty King Edward VII. the Conference of the Child Study Society, arranged to be held at Tunbridge Wells on May 19th, 20th, and 21st, has been postponed to June 10th and 11th.—The Council of the Edinburgh University Club of London has decided to postpone the dinner of the club already announced for May 27th until July 22nd. Sir Robert Finlay has again promised to take the chair.

THE meeting of the Society of Tropical Medicine and Hygiene fixed for Friday, May 20th, is postponed to Friday, May 27th, at 8.30 P.M.

THE MANCHESTER INFIRMARY SITE.—The controversy over the question, "What must be done with the Manchester infirmary site?" still rages. The Manchester city council is as far from a decisive answer to the question, apparently, as ever it was; while the suggestions that flood the local papers are almost innumerable. One group would have a new Exchange, and a conference has been held between representatives of the directors of the Royal Exchange and the Exchange Subscribers' Association, with the Infirmary Site Committee of the corporation, but for the present the negotiations have come to naught. Another group is dead against the Exchange idea, and wants an open space, as a lung, where one would be certainly useful. But while some would secure "for all time a grand open space for thousands of our city toilers to enjoy a chat and a smoke in their leisure time," others say that instead of being a beauty spot, "it would become a lounging place for tramps and outcasts." Many more cling to the idea of an art gallery and free library. Other schemes are suggested in plenty, some more grotesque than others, but none that has seized on the public mind. In the meantime the old building, with all its associations of grave and gay, has been razed to the ground, the last portion to fall being the fine Ionic columns that adorned the entrance.

THE AIMS OF MEDICAL EDUCATION

AND THE TEACHING OF THE EARLY SUBJECTS OF THE MEDICAL CURRICULUM.

(*An Abstract of the Introduction to the General Report upon Medical Education Prepared at the Request of the President of the Royal College of Surgeons in Ireland and Submitted to the Council of the College, February, 1910.*)

BY A. CAMPBELL GEDDES, M.D. EDIN.,
PROFESSOR OF ANATOMY IN THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE aim of medical education is to produce competent general practitioners, who can observe with accuracy, who can draw logical deductions from the facts observed, and who possess minds receptive of new ideas. It is not the aim of medical education to produce anatomists, physiologists, or bacteriologists; nor is it its aim to produce specialists in the various departments of medicine and surgery. Specialised scientific knowledge is rightly the product of post-graduate work.

The governing factor in the determination of all medical curricula is the time available. It may be at once admitted that the minimum period of five years is all too short for the evolution of a scientific practitioner from the raw material of the schools; but from the economic point of view a minimum of five years seems to be the practicable maximum.

During his years of study the developing practitioner not only gains nothing from his profession but has to live and to pay for his education. Even with the five years' minimum these charges represent a considerable capital outlay, and at its end a further outlay is usually necessary as a preliminary to earning more than the barest competency. It is obvious, however, that whatever period be selected as the compulsory minimum, the average duration of the student's course must exceed it. Not even the most brilliant can obtain their qualification in a shorter time, and even they, through ill-health or as a result of domestic or financial difficulties or, deliberately, through a desire to enter more fully into the study of some one or other of the subjects of the curriculum, may take more than the minimum time to obtain their qualification. Similarly for all the less brilliant. At the other end of the scale of intellect there are men who learn slowly and cannot hope to attain to the pass standard in the time officially contemplated. There are still others who only devote a part of their day to medical study, and these cannot hope to get through in less than six or seven years. Finally, there are the idlers who do not try to acquire knowledge until parental pressure becomes extreme. Under such circumstances the average time taken by students to pass through their course of professional studies alone gives little index of the reasonability of the demands of a curriculum.

At present medical education is in a state of unstable equilibrium, for among those interested there are two parties which have tacitly assumed that the five years' curriculum is incapable of producing scientific practitioners. The one maintains that the goal of formal medical education is to endow the student with a broad outlook upon the science and art of medicine; the other, that it is to equip the student with a knowledge of the details of treatment. A course of medical education based on this latter ideal must inevitably produce practitioners whose life work will be guided by rule of thumb, whereas all courses based on that must be essentially dishonest. Surreptitiously, it seeks to extend the minimum curriculum from five years to seven or eight. If the men who receive their qualification from a licensing body can afford and have the wisdom voluntarily to continue their pupilage as resident surgeons or physicians in some general hospital, or in attendance at some specialist clinique, for a period of two or three years, they may develop into highly efficient practitioners, but only in name will they be the product of a five years' course of studies. But these are extreme views, and between them the best solution of the difficulty is to be found. It is that the schools should insist upon just so much knowledge of recognised clinical methods as will make the young graduate a tolerably safe practitioner, and that the remainder of the available time should be devoted to instilling the broad outlook. In short, the time-limit compels compromise.

Amid the clash of vested interests a satisfactory compromise is difficult of attainment; a necessary preliminary to attempting it is to analyse the aim of medical education.

It is true that the ultimate aim is to produce competent practitioners; but the proximate aim is twofold: first, to educate minds to an understanding of the facts of life; second, to give sound, if elementary, technical training. Elementary the training must be; for the elements are essentials, and there is no time to produce universal specialists. For an examining body to strive to insist upon a detailed knowledge of the whole of medicine, surgery, and midwifery is wrong, and stultifies the whole object of education. To acquire such knowledge within the short time available demands cramming, and cramming is the curse of the medical schools. But apart from that, the most busy and successful practitioner does not carry all his available knowledge in his head. He knows in what books to look for unusual information. For this very reason every practitioner should have learned as a student how to use books. Such knowledge is the best prophylactic against premature senescence. In short, the proximate aims of medical education are:—(1) To teach a man to observe; (2) to strengthen his powers of thought and deduction; (3) to give him a broad outlook on the science of life; (4) to teach him the actual details of the treatment of injuries and emergencies and the common ailments; and (5) to teach him how to use books—the common memory of the profession.

To construct an outline of the aims of medical education is not difficult; it is not easy to solve the problems that hinder their achievement. It is a platitude that a school is made successful neither by its curriculum alone, nor by its equipment alone, but by these and the work of the men who are its teachers. But important as is the question of *personnel*, to obtain good anatomists, good physiologists, good pathologists as teachers is the beginning, not the end, of the problem of the teaching staff. To coördinate the work of the departments and thus to save all possible time is more difficult by far. It seems, indeed, as if what many schools lack is some coördinating authority which, through its control of the purse, has power to make its rulings operative. The composition of the controlling body must differ in different schools; but it is useless to expect the faculty to control the strong man whose energies overshadow theirs, or the scientist who is a poor teacher but whose researches are truly brilliant. If the faculty are friendlily disposed to one another, their friendship makes them lenient judges; if they are rent by dissensions, every decision is the result of faction voting. At best the decisions of a committee are the result of compromise; and when the medical curriculum, on a five years' basis, must itself be a most carefully balanced compromise, there is no room for further compromises. One solution would be to have an individual acting as controller and coördinator. Coördination of effort is the keynote of success in commercial enterprise; there seems no reason to suppose that coördination of effort will not make for success in the sphere of medical education; and just as men to manage, to direct, to control are needed in all large business undertakings, so they are required in all medical schools.

The duty of such a "managing director" should be to secure perfect coördination between the teaching departments, to prevent overlapping or lacunæ in the instruction of the student, to secure so far as funds permit a steady output of original work from the school's laboratories, to make provision for post-graduate courses, to lighten, so far as possible, the load of administrative work and financial responsibility which cramps and hinders the heads of all large teaching departments.

Granted that a competent staff, alive to the needs of modern education, has been secured, and granted that coördination of the departments has been provided for, it is essential to find and to adopt the best methods of educating the student and of imparting to him all requisite technical instruction. It has been hypothesised that the proximate aim of medical education is to teach a student to observe, to strengthen his powers of thought and deduction, to give him a wide outlook on the facts of life, and to make him familiar with the details of the treatment of injuries, cases of emergency, and the common ailments of mankind, and how to find any further information he may require in books. It is clear that this syllabus of training is readily divisible into two parts, the first purely educative, the second almost as purely technical. Methods suitable for imparting instruction in the educational part of the curriculum may be altogether unsuitable when the technical portion is reached.

But this division of the aims of medical education is not the greatest difficulty that confronts him who would recommend the adoption of particular methods of instruction. The real difficulty is presented by the extraordinary differences in mental development shown by the students within the walls of one school. Not only are the natural mental powers of students vastly different, but of a group of freshmen some are callow schoolboys, others graduates in arts, still others are well versed in chemistry, physics, and perhaps biology. Each student presents a different problem. In some cases it is necessary to educate senses; in others, minds; and if that be once effected the subsequent technical training presents no real difficulty. But senses and minds will never be educated if students are treated as driven cattle. From the very earliest moment of their entry into the school of medicine the students should be, must be, if the best is to be made of them, taken as individuals and studied by their teachers. In fact, if this be faithfully done at the outset of their medical career, it matters less how they are dealt with later. The start of the curriculum is the critical part, and it is necessary that the methods adopted there should be far more elaborate and the supervision exercised far closer than is advisable in the later subjects. Whether the studies of the curriculum be regarded from the educative or from the technical point of view, they divide themselves sharply into two groups. In the first group the normal is studied; in the second the abnormal. This division is readily recognisable, and it is convenient to utilise some natural subdivision of the courses of the curriculum to mark off the subjects in which close supervision should be exercised from those in which the student should be encouraged to accustom himself to the apparent absence of higher control; for there are few things so demoralising to the student as unequal treatment in the different departments which he has to attend in any one term.

The subsequent discussion of methods of education refers exclusively to the earlier subjects of the curriculum—viz., the subjects of the first and second professional examinations. Every teacher of these early subjects must have observed, with feelings akin to despair, the manner in which many students reduce their whole course of medical study to chaos by their failure to pass the subjects of their first professional examination, and failures are far more often due to inexperience than to laziness or real stupidity. In the present writer's opinion much of the difficulty experienced by students at the commencement of the curriculum is due to their failure to appreciate the importance and bearing of their practical work. To get practical work well done it is necessary to convince the student that the doing of it is worth while. A student's outlook is limited, and "worth while" to him means obviously worth while. "Obviously worth while" in turn means a direct help to him in getting through his examinations. Now it is impossible to train a student to observe for himself without making him do practical work, and it is not easy to devise an examination which will fairly test a student's power of observation and of doing practical work. It is easy, however, to discover a student's aptitude for these things by noticing his progress from day to day throughout the whole course in any one subject.

The daily work is the work that tells at an examination; but the student frequently does not realise this and wastes the most valuable part of his education. The whole level of medical education will be raised when the student is compelled fully to realise the importance of regular and diligent performance of practical work. There does not seem to be any way of doing this except by making the proper performance of practical work throughout whole courses an integral part of the professional examinations. To do so would be to introduce no new principle into medical education. Already attendance at courses is insisted on. All that is now required is to carry this principle further, and to make really diligent and regular study compulsory. Not only is it advisable to make really diligent attendance at practical courses count as a part of the professional examinations, but diligent attendance at lecture classes should

also count. Frequent written examinations do not diminish but intensify the educative value of lecture demonstrations, and are in themselves highly educative. Very short papers once a week are of the greatest possible value. They teach students to arrange their knowledge and to express themselves clearly, and their frequency prevents cramming. To keep abreast with them at all students have to work regularly. To teach regularity in work is one of the objects of a medical school. Alternating periods of idling and cramming are the result of occasional examinations. With weekly examinations, examination fever ceases to be a trouble, and a high uniform level of work is maintained. Even the examinations are robbed of their terror and become highly educative. There seems every reason to believe that to make the work done from day to day count towards a pass in the professional examination would do much to solve the problems that surround us. But the professional examination would require to be retained as a goal, and should be treated by the teacher as the grand revisal of the class work. The utilisation of the results of the class work as an integral portion of the professional examination may be objected to as involving too close a supervision over the students. It must be remembered that it is only recommended by the present writer in the case of the subjects of the first and second professional examinations with which the present discussion is alone concerned.

With regard to the manner of instruction, and still dealing purely with the study of the normal, it may be said without hesitation that the set lecture illustrated by blackboard drawings and diagrams alone is an anachronism. Practical work is the essential thing; but as time is short and must be saved there must also be lecture demonstrations. It is almost useless to turn students loose in a laboratory to do something. They must be told what to do, and shown how to do it, then they must go and do it for themselves, and through it all the teacher must weave threads of connecting thought. To do this demands that the subjects studied are so arranged that the thought may grow naturally and easily, and above all, that regardless of departments, subjects are dealt with as a whole. For example, it should be impossible that a student should have described to him the macroscopic structure of the human heart one winter; the microscopic structure and something of the phylogenetic and ontogenetic history of the same organ at different parts of the next summer; the circulation of the blood and the function and sounds of the heart the following winter; that he should himself make a dissection of the organ the summer after that; and that he should be permitted to delay the successful demonstration of his understanding the principles of the construction of pumps until a date even subsequent to that again. At present in many schools he may do this, and the crowning absurdity is that before he has commenced his disjointed studies he may be working in the wards of a general hospital. Such a travesty of education should be impossible. The student has not time to waste. He should be helped in every possible way to acquire sufficient knowledge of the normal to enable him to understand the nature of disease and its treatment. To save time in the early years of the curriculum is to gain time for the study of the clinical subjects.

SANITATION IN INDIA.

III.[1]

HOSPITALS AND DISPENSARIES (*concluded*).

Eastern Bengal and Assam.

Colonel R. Neil Campbell, I.M.S., furnishes the report for the hospitals and dispensaries of Eastern Bengal and Assam. On the last day of the year 1908 there were 522 of these institutions open. The total number of in-patients rose from 24,455 in 1907 to 26,246 in 1908, and the out-patients numbered 3,245,167, in comparison with 3,059,349 for the previous year. The reasons given for the increase of the patients are the progressive popularity of the institutions and the unhealthiness of the localities, while in the case of Demagiri the admissions were increased by coolies imported for the construction of the roads from Demagiri to Lungleh.

The largest number of admissions was due to worms, this being 562,590, or 17·2 per cent. of the total treated; the figures in 1907 were 507,304, or 16·6 per cent. Malarial fevers and skin diseases come next. There were 201 cases of carcinoma and 173 of sarcoma. Dysentery, and especially cholera and diarrhœa, showed a marked decrease. Goitre was particularly prevalent in the Naga Hills, there having been 2590 cases. The surgical operations which were performed amounted to 77,363, as compared with 76,366 in 1907. The operations included amongst others those for aneurysm, operations on the skull and brain, laparotomies, nephrotomy, and operations for stone (112).

Central Provinces.

In the report for 1908 for the Central Provinces by Colonel P. A. Weir, I.M.S, we are informed that 269 dispensaries were at work, treating both indoor and outdoor patients to the number of 1,731,282. The chief diseases were malarial fevers, skin diseases, ulcers, eye affections, and respiratory and digestive diseases. Malarial fevers headed the list. Cholera occurred in 17 districts, whilst dysentery and diarrhœa were more prevalent.

Madras.

The General Hospital, Madras, treated 52,243 out-patients and 7512 in-patients; the average of the latter was the highest of ten years, a marked increase being shown both amongst Europeans and non-Europeans. With regard to the former, the total number in the last ten years has been falling off, probably due to the fact that the private practitioners in Madras are yearly increasing in number. This would be more likely to affect the European than the non-European population. 7396 operations were performed. Cholera was present in an epidemic form in Madras from August to October.

Coming now more particularly to the facts noted, Major C. Donovan, I.M.S., in his summary makes some interesting remarks on certain diseases In regard to malaria, his method of treatment is to give a single dose of 30 grains of quinine, with "the happiest result as far as the cure of the disease is concerned." He quotes a case in which three species of malarial parasites were present on the admission of the patient. After the dose of quinine he remained free for 19 days, when the temperature rose, but only one species was then found. After another 36 days of apyrexia a second relapse took place, when only a second species (a different one) was found. This would favour, in a way, Laveran's views that the parasite of malaria constitutes a single species with three varieties. A case of cerebral malaria is recorded; the patient was admitted moribund, and the cerebral capillaries were plugged too extensively to admit of relief. A case of blackwater fever is recorded in which quinine in two doses of 10 grains brought on the hæmoglobinuria; and Major Donovan throws out the suggestion that the severe form of paludal fever is due to a distinct form of laverania, the parasites being of a peculiar shape.

Kala-azar gave rise to 59 admissions; the cases were all diagnosed except four by the detection of leishmania in the peripheral circulation; in one of the cases after death this organism was found in the solid viscera. This disease is very limited in the Presidency, being confined to the municipal boundaries of the corporation of Madras, and to Blacktown particularly. Major Donovan gives a succinct account of the history of the parasite and discusses its proper place in classification; he does not now locate it amongst the sporozoa. With regard to its transmission, he made observations by feeding bed bugs on kala-azar patients, but without success, and on searching for some other blood-sucking insect he came across a red and black bug which may possibly be a causative factor. In the treatment of the affection he has administered quinine by the mouth and by intramuscular injection, liquor arsenii et hydrargyri, both with and without vinum antimoniale, fuchsin, and thymol. The amelioration under fuchsin, which at first seemed to be satisfactory, proved only transient. One case, however, is narrated in which, 18 months after the treatment, the patient is in perfect health.

Major Donovan also relates a very interesting case in which he states he mistook kala-azar for typhoid fever. A patient was suddenly taken ill with a continuous temperature of 104° F. (more or less) for a week before admission. The temperature then remitted, and after 35 days came to normal by lysis exactly like typhoid fever. There were pink roseolæ, tympanites, right iliac gurgling, slight enlargement

[1] Nos. I. and II. were published in THE LANCET of May 7th (p. 1289) and 14th (p. 1369) respectively.

of the spleen, and Widal's reaction (1–100). On the twenty-eighth day of apyrexia he was discharged apparently cured, but a few days after he returned with a remittent fever of 101°–103°. The Widal reaction was now negative, and two leishmania organisms were found in the blood. But could not the patient have really had enteric fever in his first attack?

In the treatment of amœbic dysentery in early cases, Major Donovan has found Dover's powder to act like a charm; this, if found elsewhere to be the case, is an observation of the greatest value.

Captain E. W. Browne, I.M.S., relates an interesting case of kala-azar in which, after a severe erysipelas of the face and scalp, the patient began to put on weight, and his spleen so steadily diminished in size that there are hopes of his entire recovery. Other cases have been recorded in which recovery has taken place after some acute illness or complication, and this one may eventually be classed with them. He also records nine cases of seven-day fever, in one of which there was a profuse, somewhat measles-like rash.

THE JAILS.

We have received the reports of the jails for Eastern Bengal and Assam, the North-West Frontier Province, the Central Provinces, Bombay, and Bengal.

Eastern Bengal and Assam.

Lieutenant-Colonel R. R. Weir, I.M.S., in his administrative report of the 59 jails of Eastern Bengal and Assam, shows that 38,321 prisoners were admitted during the year 1908. Of these Mahomedans headed the list, next came the Buddhists or Jains, and the lowest amongst the native religions were the Hindoos, although the increase in this class was considerable. There was a satisfactory decrease in the number of juvenile prisoners admitted during the year.

With respect to the vital statistics, the daily average number of prisoners was 7766 with a daily admission rate per 1000 into hospital of 34·62, and a death-rate of 31·29. As to the diseases affecting the prisoners there were 16 cases of cholera with 14 deaths. Dysentery on the whole showed a decrease compared with 1907, but was markedly more prevalent in the jails of Dacca, Rampur-Boalia, and Noakhali. In the last there was no mortality, but this was high in the others; overcrowding was responsible for the increase. Malarial fevers were more prevalent in 1908, and so was pneumonia. There were 27 admissions for enteric fever, 26 of which occurred in the Rampur-Boalia jail, due, according to Lieutenant-Colonel Weir, to the prisoners having to bathe in a tank lying outside the jail, whilst also the trenching of the night soil was under suspicion. There were cases also of epidemic dropsy and beri-beri.

Bombay.

Major J. Jackson, I.M.S., furnishes the annual report for 1908 for the Bombay jail department. The number of prisoners in all the Bombay jails was 90,408. One very important subject is commented on by the Inspector-General—namely, the recidivist question. He holds that if every proved habitual criminal was deported for life to the Andamans or was sentenced to indeterminate punishment, the good done would be enormous. This class forms only about 13 per cent. of all the prisoners in the Bombay Presidency; and it is the source of corruption in prisons, of expense to the police department, and of injury to the public. Major Jackson's remarks concerning the classes of criminal, long term and first offenders, are well worthy of consideration.

The ratio of deaths per 1000 was 17·4, against 20·3 in 1907; this is the lowest death-rate on record, with the exception of 1905, when it was 17·1. This is extremely satisfactory, as malaria was very prevalent in some districts, whilst at Hyderabad there was an epidemic of cerebro-spinal meningitis. Major Jackson pays a well-earned tribute to the superintendents and medical officers on the attainment of this satisfactory result.

Regarding the prevalence of malaria, Yerarda prison shows the beneficent effect of an issue of quinine throughout the year, as there were here only 287 admissions, compared with 673 in 1907. The two outbreaks of cerebro-spinal meningitis resulted in 12 deaths. The outbreak showed the urgent necessity for enlarging and improving the hospital of the prison. As Major Jackson says: "To treat in such a hospital pneumonia, dysentery, and cerebro-spinal meningitis under prison conditions is a heart-breaking task."

Bengal.

The yearly report of the Bengal jails for 1908 is furnished by Lieutenant-Colonel W. J. Buchanan, I.M.S. There have been received during the year 112,028 male and 4721 female prisoners. This was a very great increase over the admissions for 1907, amounting to over 1500 prisoners. This number is sufficient to fill four or five district jails of average size. The necessary overcrowding had naturally a bad effect on the health of the prisoners.

Under the wise administration of this energetic medical officer a juvenile jail has been started, and proposals are before Government for a special jail for habitual criminals of the most determined character, so that the two extremes of the present prison administration will soon be dealt with in a special way. The improvement in the pay of the warders has given considerable satisfaction, and they have well earned it, for their duties are onerous and none of them get a full night's rest in bed, every warder having to take duty during some watch of the night. In order to remedy this Lieutenant-Colonel Buchanan has asked for a very considerable increase of the warder staff. He has also drawn attention to the buildings attached to the jails, much improvement and enlargement being necessary, while the non-advisability of using prisoners as warders is dealt with, this system having proved a failure—in fact, nothing that is important seems to have escaped his notice as he passes in review the matters connected with the various jails under his administration.

With regard to the diseases that were rife during 1908, cholera appeared in 16 jails, causing 57 deaths. The disease was always introduced from outside. Dysentery showed an increase, and was of a bad type; and Lieutenant-Colonel Buchanan here gives an appreciative notice of the good work performed by Captain W. C. H. Forster, I.M.S., at Midnapore. Owing to the shortness and early cessation of rains, there was a decline in the number of cases of malaria. Quinine was in all the jails given as a prophylactic.

North-West Frontier Province.

In the excellent report by Lieutenant-Colonel G. W. P. Dennys on the jails of the North-West Frontier Province space compels us only to notice his remarks concerning the prophylactic use of quinine in malaria. Under his direction the superintendents of the Dera-Ismail-Khan and Peshawar jails made observations on three gangs of men. The first gang received no quinine at all from July 1st to Nov. 30th; the percentage of sick from malaria was 39·3. The second gang received 5 grains of quinine every day after the morning meal; here the percentage was 7·1. The third gang received 15 grains on the fifth and sixth day, with a resulting percentage of 10·7 sick from malaria. The first method of giving the quinine here was the best. But at Peshawar a curious result is shown. The first gang of 53 men receiving no quinine had 25 admissions of malaria during the same period; the second gang of 53 taking 5 grains of quinine daily had 49 admissions; and the last gang of 53 taking 15 grains every fifth and sixth day had 53 admissions from malaria. Major A. J. Macnab, I.M.S., under whom these cases were, can offer no explanation for this result.

Another interesting fact in the report is the reappearance of typhus fever in the Peshawar jail after an interval of seven years. The management of the cases by Captain E. C. Hepper, I.M.S., is deserving of the highest commendation. He treated the outbreak on the supposition that the bed bug was the propagating agent. The sick and "contacts" were isolated. The hospital ward was disinfected, and the iron cots in which the prisoners slept were exposed to the action of fire and were also washed with perchloride of mercury. One case only occurred after these precautions had been taken. Captain Hepper has since instituted a more satisfactory method of ridding the iron cots and cubicles of these vermin by means of the Vesuvius blow lamp. The use of these lamps now constitutes a regular ritual in jail hygiene.

LUNATIC ASYLUMS.

Bengal.

The triennial report of the lunatic asylums in Bengal for the years 1906–08 is by Colonel R. Macrae, I.M.S. A great improvement in the management of these institutions has occurred since 1906. Instead of the duties being performed as heretofore by the civil surgeon of the district—whose multifarious duties and perhaps want of special knowledge interfered with his efficiency—a separate expert medical officer has been appointed and has held charge at the asylum

at Berhampore. It is to be hoped that this will be the rule elsewhere.

Statistics of the triennium under notice are embodied in the report, relating to admissions and discharges, religion, sex and age, previous occupation, types of insanity, causes, and establishment. There was an average of 851 cases in the triennium as compared with 822 in the previous one. There has been only one case of cholera. Fevers have decreased owing to the use of quinine as a prophylactic. Bowel complaints have steadily decreased, and here it is noted that the treatment by anti-dysenteric serum met with but little success. Tuberculous patients undergo the open-air treatment in tents to their great benefit. Mania was the chief predominating form of lunacy.

Central Provinces.

Colonel P. A. Weir, I.M.S., furnishes the report for these institutions in the Central Provinces for the triennium 1906–08. The principal administrative change in these provinces has been the removal of all female lunatics from Jubbulpore to Nagpore in 1907, where the site is well drained and capable of expansion. The admissions showed a distinct tendency to increase, due partly to the high prices and hard times rendering it difficult to support insane relatives, and partly to an increasing trust in asylums. With regard to the health of the lunatics, that at Jubbulpore was good, but at Nagpore not so good, the daily average of sick for the three years of the triennium being respectively 2·66, 2·78, and 2·06, and 4·25, 3·07, and 3·07. Mania was the most frequent type, existing in 90 per cent. of the admissions for the triennium; then came melancholia with 6·5 per cent.; idiocy, 2·0 per cent.; and dementia, 1·5 per cent. Of the cured and improved cases mania again formed 93 per cent. Ganja smoking was found to be the most frequent of the physical causes.

Eastern Bengal and Assam.

In his triennial report for Eastern Bengal and Assam for the years 1906–08 Lieutenant-Colonel R. Neil Campbell, I.M.S., states that there were 328 admissions, compared with 284 in the previous triennium. Ganja smoking here again headed the list of causes, whilst mania was the most frequent type of insanity. The death-rate for 1908 was greater than in 1906, but less than in 1907. Tuberculosis was the chief cause of death, but this is now lessening owing to the careful segregation of tuberculous patients. The other chief causes of death were exhaustion of mania, cholera, anæmia, remittent fever, epilepsy, and bowel complaints. The cases of cholera were all sporadic. The rate of mortality in 1908 was lower than in all the other provinces of India, with the exception of Burma and Bengal. The small steady increase from year to year in the number of lunatics treated in the asylums, and the constant reports of overcrowding evidently give support to the proposal, which is now under discussion, to build a central asylum for this province.

VACCINATION.

The reports concerning vaccination that we have received give the following statistics:—

Province.	Number of vaccinators.	Number of operations.	Number of primary operations.	Number of revaccinations.	Successful results per cent.	
					Primary.	Secondary.
1. North-West Frontier Province	35	91,368	81,181	10,187	98·38	82·14
2. Eastern Bengal and Assam ...	1130	1,449,658	1,349,379	100,279	98·80	74·19
3. Bengal	2653	2,241,576*	1,936,869	304,707	99·37† 98·60‡	62·64† 60·39‡
4. Central Provinces	—	639,647	553,438	86,209	99·10	74·99
5. Burma	259	382,336	—	—	93·58	—

* Returns from Pal Laharu and Orissa received too late for inclusion.
† Rural. ‡ Municipalities.

Nature of lymph: 1. North-West Frontier Province: Glycerinated lymph, nearly all; animal lymph, small number. 2. Eastern Bengal and Assam: Glycerinated vaccine; humanised vaccine in Rajshahi only. 3. Bengal: Lanoline lymph, mostly; lymph direct from calves; arm to arm. 4. Central Provinces: Glycerinated lymph, 99·89 per cent.; lanolinated lymph, 0·04 per cent.; fresh calf lymph, 0·03 per cent. 5. Burma: Glycerinated lymph, mostly; lanoline vaccine; quinated vaccine.

Returns furnished by: 1. North-West Frontier Province: Lieutenant-Colonel W. P. Dennys, I.M.S. 2. Eastern Bengal and Assam: Major E. Wilkinson, I.M.S. 3. Bengal: Lieutenant-Colonel F. C. Clarkson, I.M.S. 4. Central Provinces: Colonel P. A. Weir, I.M.S. 5. Burma: Major C. E. Williams, I.M.S.

Commenting on the above large amount of work, we find that no less than 4,804,575 vaccinations were performed; nor does this number represent the whole extent of this beneficent operation in India, for the returns from Bombay, Madras, and the Punjab are not included. To any medical officer in charge of a native regiment 30 years ago the beneficial effects of vaccination must be at once apparent. At that time probably the major number of recruits presented well-marked signs of small-pox; now it is the exception. We commend this fact to the notice of anti-vaccination advocates. It is satisfactory to note that the practice of inoculation is dying a natural death. Doubtless as soon as the religious convictions have been overcome the natives of India will all participate in the benefits of vaccination. An example of such prejudice occurred in one of the villages of Eastern Bengal and Assam, where vaccination was not accepted through fear of offending the goddess Basanta. In this village the highest death-rate from small-pox was reported.

The Government of India has been indebted in connexion with vaccination to the generous assistance of influential zemindars, like that of Rai Mani Lall Singh Roy Bahadur of Chakdighi.

In concluding these necessarily somewhat abbreviated notices of the Sanitary Reports from India, we cannot help expressing our admiration for the enormous work done by the officers of the Indian Medical Service. That service is, indeed, a most valuable asset to the Indian Government, and this is apparent whether we look at the subject in its prophylactic aspect, as in the matter of small-pox or malaria, for example, or in its curative aspect, as evinced by the magnitude and number of its surgical operations. Whilst all the above reports are evidences of unremitting labour, we would especially draw attention to the excellence of those drawn up by Lieutenant-Colonel Dennys, Colonel Macrae, Major Williams, and Colonel King, which are, indeed, models of what reports should be.

INTERNATIONAL HYGIENE EXHIBITION, DRESDEN, 1911.

A MEETING took place on Thursday, May 5th, at the Hotel Cecil, in connexion with the International Hygiene Exhibition, which is to be held in Dresden next year.

Sir WILLIAM LEISHMAN, on taking the chair, pointed out that the forthcoming exhibition promised to be a still more imposing one than he had at first been led to believe. He referred to the preliminary work of organisation, and then called upon the organiser of the scientific department to report on the action which he had taken since the matter had been placed in his hands.

Mr. H. W. ARMIT gave a short account of the work, mentioning that the assistance of the Board of Trade and the Foreign Office had been promised, and that the Colonial and India Offices were forwarding the invitations to participate in the exhibition to their respective Governments. After some lists of names had been read, a British National Committee, consisting of some 271 ladies and gentlemen, was elected. Mr. Armit pointed out that he had met with considerable difficulty in compiling some of the lists, since lists had been set up in Dresden which included many names which he had been unable to trace. It was only after much patience had been expended that he had been able to issue invitations to the best representatives of hygiene in the United Kingdom. He had been forced to defer the work of selecting representative hygienists in the Colonies and India, but he was now in communication with a number of Canadians, Australians, and South Africans, as well as many representatives of the Indian Empire, from all

of whom he hoped to receive assistance in this task. With regard to the posts of honour, he would suggest that he be instructed to approach H.R.H. Princess Christian to beg her to consent to become patroness. Her Royal Highness had intimated that she would wish to receive a list of the committee when it was elected, prior to determining whether she could join the committee. With regard to the post of President, he reported that he had consulted a number of active members and had received several valuable suggestions.

It was resolved that H.R.H. Princess Christian should be asked to become patroness to the British National Committee, and that certain noblemen be approached in a definite order with the view of one of them accepting the office of president. A number of names for vice-presidents were then chosen. The next business was the election of the Executive Committee. Mr. Armit read a list of names of experts for each group and sub-group of the exhibition, explaining that if the meeting pleased to elect a large committee the work would be considerably lightened, since it would be possible to avoid meetings by appealing to one or other expert on the lists for advice and reporting the action taken on this advice to the other members by circular letter. The Executive Committee consists of 121 hygienic experts and has the power of coöption. Care has been exercised to include in each group such prominent officials, medical officers, and other experts as would guarantee success to the undertaking. Especial representation has been given to organisations dealing with the hygiene of women's work and of infant life.

A vote of thanks to Sir William Leishman for taking the chair was passed by acclamation.

ENGLISH-BREWED LAGER BEER.

IT has been said that the English temperament is averse to light beers and that the climatic environment of these islands encourages the consumption of robust liquors. The fact, however, that in countries situated further north than the British Isles, and which are more remote from the influences of the Gulf Stream, the consumption of light brewed beers is the rule, discounts this view. England, Scotland, and Ireland undoubtedly are the chief producers of strong brewed malt liquors, and elsewhere very little attention is paid to their production on any significant scale. This position, however, has long been threatened by a very real demand on the part of the public for beverages which, if alcoholic at all, shall contain as far as possible a minimum of this stimulant. A score or so of years ago the idea of brewing at Burton, the world-known centre of the brewing industry, light beers equal in character, quality, and palatability to the lager or bock beer of the continent, was scorned, and yet to-day more than one well-known firm of brewers at Burton have devoted large sums of money to the erection of a plant for the production on a large scale of a light malt and hop liquor offering the pleasing, wholesome qualities of the light beers known in this country under the generic term of "lager."

Lager implies a stored or matured beer, the word itself meaning a storehouse. Storage implies time, and time means expense. The essential difference between English beer and lager beer is that the former is brewed at a comparatively high temperature and the latter at a low temperature. The work of the yeast in lager beer proceeds at the bottom of the vat, the so-called bottom or sedimentary fermentation, while in the brewing of English beer the fermentation at the higher temperature proceeds at the surface and much more rapidly. Surface fermentation succeeds therefore in preparing briskly foaming and strong beers, bottom fermentation produces the cold light lager. The products are different in flavour, in nutrient value, in alcoholic strength. Some people imagine that lager beer is flavoured with garlic. That is not the case. The peculiar taste has its origin entirely in the mode of fermentation adopted. A matter of genuine dietetic importance is the fact that while lager beer contains a higher proportion of nutritive substances than ordinary brewed Burton ale the amount of alcohol in it is decidedly less, while the process is conducted throughout not only in the cold but under seal. Lastly, the beer is preserved by a carefully conducted method of pasteurisation, the object of which is to keep the product in a sound condition, the control over this process being such that no disturbance of the delicate flavour is incurred.

The foregoing account applies at all events to the Burton lager which Messrs. Peter Walker and Son have recently placed upon the market, the various stages in the manufacture of which our Commissioners have been permitted to see. The plant at Burton is admirably designed and spotlessly clean, and the process is kept under control by refrigerating machinery adapted specially for the purpose. After considerable storage in the cold, during which the beer matures, gets brilliant, and assimilates its own carbonic acid gas, it is delivered under pressure straight into railway vans containing two capacious cylinders surrounded with blocks of ice. It is then delivered at the London depôt where the beer is bottled and sterilised. Once it has left the fermentation vat the beer is religiously guarded against any risk of contamination by contact with air. Samples taken off the open market were submitted to analysis in THE LANCET Laboratory, and samples were also examined which were taken direct from the brewery by our Commissioners. The analyses were as follows:—

ANALYSES OF ENGLISH-BREWED LAGER BEER.

	Sample 1 (London market).	Sample 2 (direct from Burton brewery).
Alcohol by weight	3·71 per cent.	3·71 per cent.
Alcohol by volume	4 63 ,, ,,	4·63 ,, ,,
Proof spirit	8·13 ,, ,,	8 13 ,, ,,
Extractives	5·20 ,, ,,	5·56 ,, ,,
Malt sugar	1 64 ,, ,,	1·65 ,, ,,
Dextrin	2 80 ,, ,,	2 90 ,, ,,
Protein	0·50 ,, ,,	0·48 ,, ,,
Mineral matter	0·26 ,, ,,	0·25 ,, ,,
Phosphoric acid	0·045 ,, ,,	0 05 ,, ,,
Volatile acidity	0 036 ,, ,,	0·048 ,, ,,
Fixed acidity	0·261 ,, ,,	0 216 ,, ,,

The analysis brings out some important points to which already slight reference has been made; the relation of nutrient to stimulant is perhaps the most interesting. It is quite obvious that when fermentation is not pushed to anything like its limit the alcohol will be trifling in quantity, and correspondingly so much malt sugar will be unconverted. That is the case with lager. On the other hand, when the fermentation proceeds rapidly and for some time the sugars are almost completely converted, so that a relatively high alcoholic strength is obtained and a correspondingly low nutritive value. The point is of importance also in regard to the great temperance question. There can be little doubt that when alcohol is indulged in even moderately it is always better taken with food. Lager beer of the character and quality shown in the above analysis satisfies this physiological ordinance, since it supplies nourishment considerably in excess of the alcohol present. In ordinary beers the reverse is the case, the amount of alcohol sometimes doubling that of the malt extractives present. Another important dietetic point in regard to lager beer of the type of that brewed by Messrs. Peter Walker at Burton is that it contains much less hops than ordinary beer, and the fact is often overlooked that the drowsiness which is known sometimes to follow the drinking of strong beer is not entirely due to the alcohol but partly to the soporific properties of the bitter principles of the hops.

There is, of course, room for all grades of beer so long as common-sense is exercised in regard to the amount consumed, and there can be little question that from a hygienic point of view the balance of evidence is in favour of light lager beer. Therefore the step which a large brewing firm like that of Messrs. Peter Walker at Burton have decided upon is one which should earn the support of all those jealous for the sobriety and health of the community, and who are jealous also for the success of British industry. The lager beer brewed by them is a practically temperance beverage, so small is the quantity of alcohol present, and, moreover, it has a quite attractive, refreshing, clean taste, but, like the continental lager beers, with which it compares most favourably, it should be kept and consumed cold. It contains no objectionable preservatives and no foreign bitter substances.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

Borough of Hove.—The carrying out of the provisions of the Notification of Births Act in Hove has led to an interesting experiment as regards the feeding of nursing mothers. It was found that some of the mothers, although anxious to nurse their offspring, were unable to do so owing to the fact that they had insufficient food themselves, and as a result the child was relegated to cows' or condensed milk. To obviate this a mothers' and babies' fund was started by Councillor H. M. Taylor, and free dinners were commenced at the beginning of March of last year. The routine is as follows. The health visitor reports the cases of needy mothers to the medical officer of health, and, if he approves the selection, these women are furnished with tickets which are available at several restaurants, at one of which the mothers can take their dinner. During 1909, from March onwards, 32 mothers were supplied with 2322 dinners. In 4 instances the dinners lasted a month, in 11 less than three months, in 8 for from three to four months, in 5 from four to five months, and in 2 for six months, while 2 continued into 1910. As regards the results there seems to have been no doubt as to the advantage which accrued to the mothers, but it was difficult to obtain data whereby to assess the benefit to the children. Of the children whose mothers were being thus nurtured the results were disappointing in 4, and the dinners were stopped; 4 were benefited, but from other causes were not in a satisfactory condition; 2 derived advantage during the short time their mothers were being fed; 3 were enabled to be fed, although the father was ill or out of work; 2 were premature babies which did well; two twins were breast-fed for nearly five months, the mother not having formerly been able to suckle her young; 2 recovered from severe attacks of whooping-cough; 1 was, it is thought, possibly kept from developing rickets; another was one of the only two survivors out of a family of 7; another which was cross before became contented. In two cases the mothers' milk which had ceased was replenished, while the babies were enabled to be fed for three and four months longer. The remaining 8 progressed favourably. Dr. A. Griffith, the medical officer of health, regards the arrangement from the point of view of public assistance as undoubtedly a reasonable and economical one, and the cost seems very small. For 26*s.* a good and sufficient dinner for six days weekly was supplied to each mother for three months. This arrangement is somewhat on the same lines as that adopted in connexion with the anti-tuberculous dispensaries in Paris, and it was also in France that this idea of feeding suckling mothers originated.

Sidmouth Urban District.—Dr. T. H. S. Pullin is opposed to the notification of pulmonary tuberculosis because *inter alia* of "the terrible social and domestic interference and discomfort it would occasion and the financial loss to lodging-houses and hotels" which would result from the official inspections which would ensue. In his opinion, as well as that of the Devonshire county medical officer of health, this remedy "is not of the sanitary, but of the suppression type," and he holds that "to suppress a disease by a careful system of watching is not uprooting its cause, but rather straining after a pretended than a real victory." But it is surely possible to control the cause of a disease as well as to make use of the information obtained by a well-devised system of voluntary notification. Dr. Pullin has had an extended experience as a private and public vaccinator, and in that time he has never encountered a case of "insusceptibility," and only rarely of failure of one insertion out of four.

Swinton and Pendlebury Urban District.—Mr. Samuel Hosegood's experience as school medical officer during 1909 has led him to the conclusion that infectious disease is not spread to any appreciable degree by school attendance, and he regards home influence and surroundings as mainly responsible for such spread. He also sees no difficulty in dealing with the bulk of cases of infectious disease in their own homes instead of in an isolation hospital. We doubt whether many of Mr. Hosegood's colleagues in the public health service would agree with him as to this latter point, and it is, we think, generally conceded that it is impracticable to isolate cases of infectious disease in the small and often contracted homes of the poorer classes. It is true that without hospital accommodation there is frequently only one case in a household, but such an occurrence is largely explained by the circumstances. Mr. Hosegood embodies in this current volume the report of the lady health visitor, Mrs. H. A. Johnson, who tells us that there has been a marked improvement respecting the prevention of diarrhœa owing to the fact that many of the mothers are sterilising their milk and storing it under better conditions during the summer months. She meets with many difficulties in her attempts to control bronchitis and pneumonia. Parents postpone seeking medical advice; they give the baby patent cough mixtures, many of which contain opiates, and even when a medical man is called in the friends interfere with the carrying out of his treatment both as regards food and medicine. "Teething" is, she finds, responsible for the fact that medical men are not called in more frequently, since all the ailments of infants during the teething phase of life are liable to be ascribed to this process.

Goole Urban District.—Dr. A. M. Erskine gives an interesting account of diphtheria prevalence in this district, in the control of which modern methods of prevention were adopted. Owing to cases of the disease at the beginning of the year swabs were taken in the course of two days from the throats of the 525 children attending certain schools, each child being sent home directly its throat was swabbed. The examination was completed on Friday, and on Sunday the results were telephoned to the medical officer of health. Nine out of the total number examined harboured diphtheria germs, and so, Dr. Erskine adds, "were the means of continuing as carriers of the disease to others." The schools were cleansed and fumigated, and on Monday morning the nine carriers were excluded, the children being either treated by their own medical men or sent to the sanatorium where they were kept until the swabs from their throats yielded negative results. One of the carriers subsequently developed diphtheria, but it is not apparent whether this was one of the hospital cases or not. Presumably the children who were sent to the hospital were kept in observation wards and were not put into the diphtheria pavilion. No further cases occurred up to the end of 1909. But in connexion with another school things developed differently. Here there were found in one class a child who had had diphtheria three months before, another with a nasal discharge, and three teachers with sore-throat. Of the 42 children in the invaded class from whom swabs were taken six yielded positive results. The children in question were excluded, but later four fresh cases were notified from the invaded department. Apparently the resources at the disposal of the authorities concerned were overtaxed, and there is no doubt that this method of controlling diphtheria does involve an enormous amount of protracted labour on the part of both the sanitary and school authorities. Dr. Erskine, as the result of his observations as to the persistence of diphtheria bacilli in throats, finds that in bright sunny weather the carrier cases soon lose their bacilli, whereas in dull, wet weather it requires weeks before a negative result is obtained. He concludes that climatic conditions affect the life of the organism in its natural habitat—the throat and nose.

County Borough of Burton upon-Trent.—Dr. J. M. Cowie chronicles the steady decline of enteric fever in this town. From 1892 to 1901 there was an average of 46 cases yearly, but from 1902 to the present time the average has been 19. In 1902, under the provisions of the Burton-upon-Trent Corporation Act, 1901, the conversion of privies and pan-closets into water-closets commenced, and during the interval 831 privies and 1492 pan-closets have been converted. It is to this process of substitution that Dr. Cowie very largely ascribes the decline in enteric fever prevalence, and he prophesies that "as the conversion of pail-closets and privy-middens to the water carriage system is gradually completed it is certain that enteric fever will become rarer in the borough and quickly disappear just like typhus fever."

REPORTS OF SCHOOL MEDICAL OFFICERS.

The East Suffolk Schools.—Dr. G. I. T. Stewart, the school medical officer for East Suffolk, has issued his second annual report, which is of a most elaborate and interesting character. The number of children inspected during the year was 8535. In 463 instances the footgear of the children was poor, and in 52 cases it was bad. The want of boots in the East Suffolk district appears to be

a very real distress, but it is alleviated often by private charity. It is too much to expect that agricultural labourers should be able to provide adequate footgear for more than five children of school age, and there is room for an organisation that will collect and distribute cast-off but wearable boots of every size and description. A good deal is said about the want of cleanliness of the children's heads, and teachers are urged to take a firm stand on this subject. 49 per cent. of the children suffered from defective teeth, and 11 are stated to have been practically starving from not having sufficient teeth for the proper mastication of their food. Defective vision was present in 4·6 per cent. of the children, external eye diseases in 2·5 per cent., and defective hearing in 3 per cent. Defective speech was found in 57 cases, and in reference to this Dr. Stewart notes that the accent in the county is a semi-guttural one, most pronounced in elder boys, who are particularly careless of the cleanliness of their mouths, with the result that the cheeks and lips being inflamed are not used for articulation. It is also stated that in many schools the want of modulation of the voice on the part of the teacher has seemed responsible for the sing-song monotone adopted by the children. It is to be regretted that teachers, to whom the voice is so important, should neglect the first principles of voice hygiene—the care of the mouth and the use of proper modulation of the voice.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeon: H. B. Hall to the *Lancaster*, on recommissioning. Staff-Surgeon: J. Boyan to the *Bulwark*, additional, for disposal. Surgeons: G. D. Walsh to the *Pembroke*, for R.N. Barracks; A. F. Fleming to the *Lancaster*, on recommissioning; A. O. Hooper to the *Vivid;* H. Burns, R. J. G. Parnell, F. L. Smith, C. D. Bell, and A. G. V. French to the *Victory*, additional, for disposal; J. H. B. Martin, M. H. Langford, A. C. Rusack, and C. G. Sprague to the *Vivid*, additional, for disposal; T. C. Patterson, A. Fairley, F. C. Searle, and W. E. Lloyd to the *Pembroke*, additional, for disposal; and J. P. Berry to the *Wildfire*, additional, for disposal.

ROYAL ARMY MEDICAL CORPS.

Captain Richard J. C. Thompson is seconded for service with the Egyptian Army (dated April 29th, 1910).

Lieutenant Ralph De V. King resigns his commission (dated May 14th, 1910).

Surgeon-General J. G. McNeece has arrived home from Malta on relief by Colonel W. G. Macpherson, C.M.G., appointed Principal Medical Officer. Lieutenant-Colonel H. E. Cree, from Chatham, has been appointed to command the station hospital at Jhansi. Lieutenant-Colonel W. W. Pike, D.S.O., on arrival from India, has been posted to the Southern Command and appointed to the medical charge of the Military Hospital at Tidworth. Lieutenant-Colonel G. F. H. Marks, from Newcastle-on-Tyne, has been posted to Ferozepore. The transfer of Lieutenant-Colonel C. L. Josling to the Eastern Command has been cancelled consequent upon his retirement. Major F. Smith, D.S.O., sanitary officer, 2nd (Rawal Pindi) Division, has been selected for the increased rate of pay of his rank after 20 years' service in accordance with Article 317 of the Royal Warrant. Major A. W. Bewley, from Agra, has been appointed to command the station hospital at Landour. Major H. W. K. Read, from Landour, has been posted to Beverley. Major A. F. Tyrrell has been transferred from Queenstown to Fermoy. Major St. J. B. Killery, on completion of a tour of Indian service, has been posted to Jersey. Captain C. Scaife, Bombay, has been appointed a Specialist in the Prevention of Disease and placed in charge of the Brigade Laboratory at Colaba. Captain J. H. Douglass, from Secunderabad, has joined for duty at Dublin. Captain R. L. Popham has been transferred from Dublin to Cork. Captain T. E. Harty, from Mandalay, has been posted to the Eastern Command. Captain T. C. Lauder has arrived home on leave from the West Coast of Africa. Captain S. O. Hall, from Secunderabad, has been posted to Fermoy. Captain B. F. Wingate has been transferred from Ferozopore to Secunderabad. Captain S. G. Butler has joined at Pretoria. Captain H. C. R. Hime, late Adjutant Royal Army Medical Corps School of Instruction at Aldershot, has been posted to Bangalore. Lieutenant R. C. Priest, on completion of duty at Bury St. Edmunds, has rejoined at Colchester. Lieutenant O. W. McSheehy has been transferred from Devonport to Worcester. Lieutenant J. J. D. Roche has joined Dublin from the Curragh. Lieutenant J. R. Hill, from Chester, has been posted to Monmouth. Lieutenant J. R. Yourell has been transferred from Londonderry to Belfast.

INDIAN MEDICAL SERVICE.

The services of Major D. H. McD. Graves have been placed temporarily at the disposal of the Government of Madras. Privilege leave for three months has been granted to Major W. H. Kenrick, civil surgeon of Nimar, Central Provinces, undergoing a course of instruction at Amritsar. Captain C. A. Sprawson, civil surgeon of Jhansi, has been granted leave for 15 months with effect from April 14th, Captain H. W. Illius to officiate as civil surgeon during his absence. Captain J. M. A. Macmillan, officiating civil surgeon, Seoni, has been transferred in the same capacity to the Hoshangabad District. Captain J. D. Graham has been placed on special duty to inquire into the prevalence of malarial fevers in the United Provinces. Captain J. A. Cruickshank, medical officer in charge of the 26th Light Cavalry, has been granted eight months' leave. Captain W. H. Hamilton has been appointed to the substantive medical charge of the 36th Sikhs. The services of Captain L. P. Stephen have been placed permanently at the disposal of the Government of Bombay.

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st Lowland Field Ambulance: Lieutenant Archibald Jubb resigns his commission (dated Feb. 22nd, 1910).

For attachment to Units other than Medical Units.—Ernest William Reed to be Lieutenant (dated March 19th, 1910); Frank Miller Bingham to be Lieutenant (dated March 24th, 1910); William Charles Frederick Harland to be Lieutenant (dated April 6th, 1910).

Attached to Units other than Medical Units.—Lieutenant Edward F. MacL. Neave to be Captain (dated July 14th, 1908); Lieutenant David R. Taylor to be Captain (dated Feb. 18th, 1910); Lieutenant Arthur H. Falkner resigns his commission (dated March 24th, 1910); Lieutenant John H. P. Paton resigns his commission (dated March 31st, 1910); Lieutenant Arthur Innes to be Captain (dated April 10th, 1910).

DEATHS IN THE SERVICES.

Major Kenneth Mackenzie Cameron, R.A.M.C., on May 7th, aged 41 years, at the Cambridge Hospital, Aldershot, from tetanus, the result of a bicycle accident. He entered the service as a surgeon-lieutenant in 1894, was promoted to captain in 1897, and reached the rank of major in 1905. He served with the Tirah Frontier Expedition and later went through the Boer war in South Africa and was at the siege of Ladysmith.

MISS FLORENCE NIGHTINGALE.

Miss Nightingale, who in spite of her age and invalid state is cheerful in disposition, has just quietly celebrated her ninetieth birthday. On May 12th she was the recipient of the following telegram from the King:—

> Miss Florence Nightingale, O.M., 10, South-street, Park-lane.
> On the occasion of your ninetieth birthday I offer you my heartfelt congratulation, and trust that you are in good health.
> GEORGE R. & I.

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

In the May issue of this journal Lieutenant-Colonel R. J. S. Simpson, C.M.G., continues his interesting Medical History of the South African War, and Major A. P. Blenkinsop contributes a further instalment of his Notes on Military Map Reading. Medical officers, who for various reasons may have been unable to keep in touch with the subject of dark ground illumination, will find in the article by Captain L. W. Harrison on Dark Ground Illumination in the Diagnosis of Syphilis a practical descriptive summary of the necessary apparatus and methods of carrying out a convenient means of diagnosis, by which, in addition to that of the "Wassermann reaction," to quote the author, "the treatment and general management of syphilis will become a much more exact science than heretofore." In A Plea for the

Employment of Aurists in Connexion with Recruiting by Lieutenant-Colonel R. C. Cottell, the author refers to the large number of cases invalided from the army in consequence of deafness. He points out that short service after an expensive training owing to this cause is obviously a bad investment for the State, and believes that more care must be taken in testing the hearing of recruits, and that if necessary more aural specialists should be employed. "If the remedy," he says, "would even half this terrible loss, time and money would be well spent." Captain J. Dorgan gives an interesting personal experience of spinal analgesia by stovaine and describes his feelings in the course of an operation for radical cure of a right inguinal hernia.

THE RED CROSS SOCIETY.

At the annual general meeting of the council of the Scottish branch of the British Red Cross Society held on May 5th at the North British Railway station, Glasgow, it was stated that the returns received from the honorary secretaries of counties showed that there would appear to be in all but 277 members and associates of the society belonging to the Scottish branch, of whom 193 were members and 84 associates.

The President of the Suffolk branch of the Red Cross Society, the Hon. Mrs. Stirling, gave an address at a meeting of the executive committee which was held in the County Hall, Ipswich, on May 3rd. She laid particular stress upon the importance of field cooking classes, or what she might term housekeeping classes, remarking that even those ladies who were good cooks were neither accustomed to catering for dozens of invalids and their nurses, nor to cooking without the conveniences of a well-appointed house.

On May 3rd the Countess of Warwick presided at the Great Eastern Hotel, Liverpool-street, London, E.C., over a meeting convened for the purpose of forming an Essex branch of the British Red Cross Society. Mr. G. H. Makins, C.B., gave an address on the aims and objects of the movement.

A meeting of the Swansea branch of the Red Cross Society was held at the Guildhall, Swansea, on May 9th under the presidency of the Mayor, when a central committee was elected.

THE PARKES MEMORIAL PRIZE.

The subject for the next Parkes Memorial Prize will be as follows:—The Causation and Prevention of Enteric Fever in Military Service with special reference to one of the following branches of the subject: (1) the rôle played by flies in the dissemination of the disease; (2) the importance of carriers; and (3) the predisposing influence of age and length of service. This prize, consisting of 75 guineas and a bronze medal, is open for competition among the medical officers of the Royal Navy, Army, and Indian Services of executive rank on full pay, with the exception of the professors and assistant professors of the Royal Naval Hospital, Haslar, and the Royal Army Medical College, London, during their term of office.

Major O. J. Currie, late Natal Field Artillery, has been appointed to the command of B Company, Cape Medical Corps.

ROYAL EYE HOSPITAL, ST. GEORGE'S CIRCUS, SOUTHWARK, S.E.—Lectures, demonstrations on clinical cases, instruction in refraction work, and demonstrations on pathological specimens in the museum are given throughout the winter and summer sessions by the members of the staff of this hospital. Post-graduates and medical students wishing to become students at the hospital should communicate with the honorary secretary.

UNIVERSITY OF CAMBRIDGE.—The examinations for medical and surgical degrees during the Easter Term, 1910, will be held during June. The First and Second Examinations will commence on Monday, June 13th. The Third Examination (Part 1) will commence on June 15th and Part 2 on June 16th. The examination for the degree of M.C. will commence on June 18th. The names of candidates for the two latter examinations must be sent to the Registrary on or before Saturday, May 21st. Candidates who are members of the Senate may send their names to the Registrary direct. All other names must be sent through the prælectors of the respective colleges.

Correspondence.

"Audi alteram partem."

EPSOM COLLEGE.

To the Editor of THE LANCET.

SIR,—Your sympathetic article on Epsom College in last Saturday's issue, which I read with much pleasure, prompts me to write a few lines of kindly criticism and suggestion to the authorities of that great institution. I venture to think that the council might easily enlist the active sympathy of the medical profession in much greater degree than at present by giving those members of it who are, or might become, subscribers to the College opportunities of taking a personal interest in the institution.

My experience is probably not unusual, and I mention it, not in a spirit of cavil, but merely to indicate the lines on which a change might be made with advantage to the College. I have taken an interest in Epsom College for a long time; I have been a subscriber for many years; I have induced others to become subscribers; I have been the means of sending boys to the school, partly by advice, partly by helping to pay fees. With the exception of an annual visit from the collector and the reception of voting papers once a year, no indication of the existence of the College reaches me. No annual report, no notice of public functions at the College, has found its way to my address. It is true I have received invitations to banquets in aid of the institution and have been asked to subscribe to the funds then raised.

My experience of other institutions of a somewhat similar character has taught me that if we wish subscribers to take an active personal interest in any institution we must show that we take some interest in them, and it is in this particular that I think we often fail in our medical charities. I have been for some years professionally connected with a large educational institution supported by one of the chief trades of this country, and I have been much impressed by the personal interest shown by the subscribers generally, an interest warmly encouraged by the committee of management, all of whom are trained men of business.

I am, Sir, yours faithfully,

May 15th, 1910. WELL-WISHER.

TUBERCULOSIS AND HEALTH RESORTS.

To the Editor of THE LANCET.

SIR,—It has occurred to me that the majority of medical men who send their patients to recoup at a health resort are wholly unaware of the conditions of apartments, boarding houses, or hotels their patients reside in.

Not many days ago, a patient sent down here to me by her medical man complained that she had been to a health resort nearer London, and that it had come to her knowledge that the landlord of her lodgings there had chosen to live in that particular town because he was suffering from phthisis. To make matters worse, she assured me that the whole family, consisting of six persons (adults and children) lived during the time she was there in the kitchen, where everything appertaining to cooking, &c., had to be done. This so disgusted the lady in question that she removed here with despatch.

Now it is a matter of common knowledge that in every seaside and health resort in every part of the world consumptives take up their residence with the object of recovery or dragging on an existence, and making a living by letting lodgings. Under the present circumstances it is impossible for these invalids to be prevented from carrying out the business of lodging-house keeper, and I suggest that there should be some combination between medical men practising in these health resorts and those who are likely to send patients there.

In the meantime, let me further suggest that any medical man wishing to send a patient to convalesce at any health resort should, if he knows personally no medical man living at that particular place, turn up the Medical Directory and pick one doctor's name out and write to him. No doubt the medical man who receives such a request will be only too pleased to reply. As regards Torquay itself, it is, compared

to other seaside resorts, comparatively free from alien consumptives; the distance from London and the great centres prevents the poorer consumptive from undertaking the necessary expense. At any time I shall always be happy to recommend apartments, in Torquay and neighbourhood, which are without the taint of disease, and where the family live in a decent condition and at a moderate expenditure.

I am, Sir, yours faithfully,

Castle-road, Torquay. COURTENAY DUNN, B.A., L.S.A.

CHLORIDE OF CALCIUM.

To the Editor of THE LANCET.

SIR,—With reference to Dr. Moncany's *résumé* of the therapeutic uses of calcium chloride, published in THE LANCET of May 14th, will you permit me to recall the quantitative estimation I made and published in the year 1900. I estimated the amount of calcium oxide in the normal urine of 24 hours and found that it contained 25 centigrammes of CaO. I also estimated the urine of 24 hours on the third day of taking 600 centigrammes of calcium chloride (daily), and found the amount of calcium oxide had risen from 25 centigrammes to 43 centigrammes in the 24 hours. It would appear that about 7·5 per cent. of the calcium oxide taken in the day was excreted by the kidneys. I am not aware of this investigation having been previously made or followed up, but it has a very great interest in relation to the *scientific* therapeutic use of this valuable salt. The paper containing the above experiments is published in the volume of the Transactions of the Academy of Medicine, Ireland, for the year 1900. I am, Sir, yours faithfully,

Terenure, May 16th, 1910. NINIAN M. FALKINER.

MEDICINE IN FICTION.

To the Editor of THE LANCET.

SIR,—Many both in the profession and outside it will be grateful for the timely words in your leading article under the above title:—"Sexual perversion is a pathological subject, and finds its only fit place in pathological treatises." The words are timely, for this perversion already finds place in current fictional literature. A protest from THE LANCET or from the official representatives of the profession a few years ago might have been prophylactic and saved "incalculable mischief." What can they do now to arrest that mischief? I venture to assert that a great and harmful fallacy underlies your words, "Suppose we pardon these great ones on the ground that their intellect was such as to demand unfettered scope"; but let that pass, we have now to deal with small men who exploit strange lusts for filthy lucre's sake. The facts are these. The French pornographic novel can be had for the asking at French libraries in London and at some of those leading English circulating libraries which took a part in the agitation for a censorship by libraries of English books. I am told that the same statement applies to German books. "Sapphism" has for many years formed a theme of French pornographic literature, but, so far as my knowledge goes, has only recently found its way into English fiction. Some months ago an English book which dealt with this theme in a veiled but dangerously suggestive fashion was suppressed through the efforts of a private individual after it had reached a sale of some thousands. This book was almost certainly inspired by a French novel written some ten years ago (it is mentioned in the English book) which deals nakedly with Sapphism, and which was circulated and sold by one of the aforesaid English libraries. The Act which regulates police interference with poisonous literature makes no distinction between English and foreign books. The Executive does at present make a distinction in favour of foreign books. Moreover, everything may depend on the definition of the word "obscene," and this difficulty will not be got over by the substitution of another word or words. The Home Office is in possession of the facts here briefly stated. It would greatly strengthen the hands of those who are trying to tackle this nauseous business quietly and wisely if the official representatives of the medical profession would assert that "all works of fiction which deal with sexual perversion in whatever language, and whether in veiled or open fashion, ought to be summarily suppressed without regard to the plea of deterrency." Perhaps you will allow me to deal on some future occasion with the failure of our system of dealing with moral filth and moral infection. Poisonous literature has been given an even bigger start than seditious literature has had in India.

I am, Sir, yours faithfully,

May 10th, 1910. M.B. (DUNELM).

THE GERMAN SURGICAL CONGRESS.

(FROM OUR BERLIN CORRESPONDENT.)

(*Concluded from p. 1303.*)

Goitre.

Professor KOCHER (Berne) said that goitre might disappear after the administration of iodine, but that nervous symptoms very like those of Graves's disease might develop. These symptoms, however, had nothing to do with the ordinary toxic action of iodine; they were caused by a retention of the iodine in the thyroid gland, where the agent causing the above symptoms was produced. The juice of the thyroid gland had an action similar to that of iodine, and the administration of preparations of that gland, whilst beneficial in myxœdema, might produce the symptoms of Graves's disease in normal persons. The tolerance for preparations of thyroid gland or iodine was different in different individuals, and some persons have a special susceptibility in this respect, as nervous symptoms might develop after the administration of very small quantities of these substances. The treatment must then be stopped at once and phosphates must be given as an antidote. The success of thyroidectomy in Graves's disease was based on the fact that a large stock of iodine was removed from the organism by the operation.

Professor SCHLOFFER (Innsbruck) spoke on paresis of the recurrent laryngeal nerve as a sequel to thyroidectomy. He said that he had seen the paresis develop in 13 out of 600 patients on whom that operation had been performed, and if laryngoscopy was practised immediately after the operation still more cases would be detected. Of his last 30 cases 3 showed this complication, which, however, disappeared in a few days. Even with the most cautious operators the recurrent laryngeal nerve did not always escape injury. Professor Schloffer had ligatured the different branches of the inferior thyroid artery on the capsule and had left the posterior wall of the capsule on the trachea, but nevertheless paresis occurred.

Dr. LEISCHNER (Vienna) confirmed Professor Schloffer's statement, saying that he had seen 63 cases of paresis of the recurrent laryngeal nerve in 300 operations; they were all of a transitory character.

Removal of the Thymus Gland.

Dr. KLOSE (Frankfort) said that he had, together with Dr. Vogt, made experiments on dogs to ascertain the function of the thymus gland. He removed the gland on the tenth day after the birth of puppies and found that during the first two or three months they did not differ much from other dogs. After that time, however, the animals became abnormally fat and somewhat apathetic; this stage lasted for about three months, when a cachectic stage began in which the animals became progressively weaker, and death occurred with symptoms of coma. During the cachectic stage the bones showed an increased brittleness, so that spontaneous fractures were frequent. On examination of the bones delayed ossification and osteoporosis with the formation of cysts were found, the cause being a deficiency of lime in the organism, a deficiency which the speaker considered to be due to the action of nucleinic acid. The administration of thymus juice did not remove the above symptoms. Thymectomy performed at a later stage after the involution of the gland had no effect on the animals. Dr. Klose and Dr. Vogt were of opinion that the spleen replaced the action of the thymus gland in the case of older dogs.

Dr. GEBELE (Munich) said that he had made post-mortem examinations in five cases of Graves's disease, four of which showed persistence of the thymus gland. He had made experiments on dogs by implanting a thymus gland into the abdomen and removing the thyroid gland, and he found that these animals survived, whereas others died from which the thyroid gland was removed without an implantation of a thymus gland. He therefore concluded that the thymus gland might replace the thyroid gland.

Treatment of Inoperable Cancer.

Professor VON CZERNY (Heidelberg) explained the methods of treating inoperable cases in the Heidelberg Cancer Hospital. They included the use of radium, X rays, fulguration, the thermo-cautery, the electro-cautery, and Schmidt's serum. The latter method was not altogether harmless, as pyrexia might develop; its action was not a specific one, but must be compared with that of erysipelas. Treatment by means of radium was comparatively successful in three cases of cancer of the pleura; fulguration proved useful in gangrenous cancerous ulcers, which in the result presented a cleaner aspect and showed some development of granulations.

Appendicitis.

Professor KÜMMELL (Hamburg) said that the statistics of the Berlin Medical Society on appendicitis were erroneous because they extended only over one year, whilst more than 50 per cent. of the cases had a relapse after that time. He concluded from his own experience in 1500 cases that the earlier the operation the lower the mortality, the latter being only 0·5 per cent. in early cases. He considered that the diagnostic methods at present available were inadequate; the increase of the viscosity of the blood and the multiplication of the leucocytes proved the presence of peritonitis, but not the imminence of perforation, and as the surgeon was unable to ascertain the condition of the appendix an operation should be performed as soon as the presence of appendicitis was certain or even likely. He did not agree with Professor Sonnenburg's advice that castor oil should be prescribed in certain cases, neither was he in favour of puncturing a supposed abscess, as suggested by the late Professor Lenhartz.

Professor SONNENBURG (Berlin) said that in post-mortem examinations of persons dying from other diseases traces of appendicitis were found in a great many cases without the occurrence of any previous clinical symptoms. An attempt should be made to ascertain in the individual case the virulence of the bacteria, as well as the resistance of the organism, and he had used for that purpose the leucocytometer and Arneth's blood test. The greater the number of uninuclear leucocytes the worse was the prognosis. He pointed out that he had recommended the administration of castor oil only in cases where the above test had been made and only in cases where the patients were in a hospital under constant surgical observation. He had treated 300 slight cases in this way without a single failure, and he protested against the opinion that this method meant a new therapy for every acute case of appendicitis. He wished to avoid unnecessary operations which were now performed in a good many cases, the surgeons being afraid of risking the patient's life by delay. The mortality in his hospital was not greater than elsewhere. When symptoms of appendicitis persisted after the first attack an operation during the quiescent interval was to be recommended.

Professor KOCHER said that the curve of the leucocyte count was during the first days the same in slight and in severe cases, a difference occurring only when perityphlitis or peritonitis had developed; the best time for an early operation might possibly be lost by waiting until there was an increase of the leucocytes.

Professor KÜTTNER (Breslau) pointed out that during the first year of his work in Breslau the mortality of appendicitis were 29 per cent. By an active advocacy of the idea of the early operation among the profession in Breslau the medical men were induced to send the cases to the clinic on the first day of the seizure, the result being a decrease of the mortality to 8·5 per cent.

Dr. FABRICIUS (Vienna) spoke on the relation between appendicitis and gynæcological ailments. He said that appendicitis often led to abortion, and that in child-bed it was often mistaken for a puerperal complication. It might also be erroneously diagnosed as extra-uterine pregnancies, puerperal fever, hysterical ovarialgia, or salpingitis.

Dr. VON BRUNN (Tübingen) recommended in operations for appendicitis the application of primary sutures, even if an abscess was present, because abdominal hernia was avoided in this way. Instead of 69 per cent. of cases of hernia he had now only 18·5 per cent. Phlegmon of the abdominal wall might eventually occur, but need not cause alarm.

Professor KÖRTE (Berlin) spoke against primary sutures of the abdominal wall in suppurative appendicitis, but recommended sutures of the peritoneum.

Cancer of the Appendix.

Dr. NEUGEBAUER (Ostrau) said that in about 1 per cent. of the cases operated on small growths were present on the apex of the appendix. They were contained within the lymph spaces of the muscular coat and were separated from the mucous membrane. They were believed to be cancer, but must rather be regarded as non-malignant endothelioma. True cancer of the appendix, although very rare, was just as malignant as other cancers.

Treatment of Peritonitis.

Dr. HIRSCHEL (Heidelberg) recommended in suppurative peritonitis the injection of camphorated oil into the peritoneal cavity. He had treated in this way nine apparently hopeless cases of peritonitis, with five recoveries and four deaths. The patients had all the symptoms of general peritonitis, such as dry tongue, tympany of the abdomen caused by paralysis of the intestines, fæcal vomiting, and a pulse-rate of 120 to 140. The abdomen was opened, the perforation in the intestine was closed, the purulent fluid was wiped out with gauze, and from 100 to 300 cubic centimetres of camphorated oil of 1 per cent. strength were injected into the abdominal cavity with as equal a distribution of it as possible. The action of the camphorated oil was based on its faculty of obstructing the lymphatic vessels of the peritoneum, so that the absorption of toxic substances was hindered; the bacteria were also enveloped by the oil and a reactive inflammation was produced.

Professor FRIEDRICH (Marburg) recommended the injection of glycerine into the peritoneal cavity for tuberculosis of the peritoneum. He said that in experiments on animals he had found that injections of from four to six cubic centimetres of glycerine produced an enormous exudation into the peritoneum. He used this passive hyperæmia for the treatment of tuberculosis of the peritoneum. He first performed laparotomy in order to ascertain the site and the extent of the tuberculosis, and then injected from 20 to 30 grammes of glycerine. The wound was now closed and the injection was repeated after some days through the peritoneum. Miliary tuberculosis and tuberculo-serous peritonitis without adhesions were treated in this way.

The Present Position of Lumbar Anæsthesia.

Professor KÖNIG (Altona) said that as the result of a collective investigation which he had made among the leading German surgeons he had found that about 50 per cent. of them no longer used that method. The report included 2400 cases; stovaine, tropacocaine, and novocaine were administered. Failures occurred rather frequently, and undesirable sequelæ were often observed, such as headache, vomiting, paresis of the abducent nerve, post-operative pyrexia, and three cases of purulent meningitis, notwithstanding most careful asepsis. Post-operative pneumonia was not less frequent after lumbar anæsthesia than after inhalation anæsthesia. The kidneys were never injured. The mortality was 1 in 200 cases. Professor König warned his hearers against a too frequent use of the method, which was permissible only in cases where there were contraindications against both local and general anæsthesia.

Transplantation of Joints.

Professor LEXER (Königsberg) showed a series of cases in which he had transplanted joints from one person to another. The first patient had suffered from synostosis of the knee-joint after suppurative gonitis, and to relieve this the diaphyses with the ligaments obtained from a recently amputated femur were implanted. Plastic operations on the extensor muscles were then performed. The patient had fairly good use of the limb, and the result proved that a transplanted knee-joint might remain serviceable for two and a half years. In another case a precisely similar operation was performed four months ago, the joint being already capable of flexion through an angle of 30°. The third patient was a man, the lower part of whose ulna had been resected for central sarcoma, and a piece of tibia had been implanted two years ago. The implanted bone became united, and a kind of articulation with the carpal bones was obtained with normal function of the joint. The fourth patient was a girl, the upper part of whose left tibia with the cartilage of the joint was resected and replaced at once by implanting a piece of a foreign tibia with the epiphysis.

The medullary cavity of the bone was filled by a fresh piece of fibula with periosteum. The patient was now able to walk on crutches and could even ascend stairs. This operation was performed eight months ago.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Appointment of District Medical Officers by Rotation.

AT a meeting of the Aberdeen parish council held on May 10th Dr. James Robertson was appointed a district medical officer in room of Dr. F. Kelly. Dr. Kelly's retirement took place according to a system of rotation adopted by the parish council of Aberdeen about two years ago, by which one of the five district medical officers retires every year. In reference to this rotation retirement the clerk read the following letter from the Local Government Board, dated April 26th last:—

Referring to your letter dated 14th inst., intimating that, according to the system of rotation adopted by the parish council of Aberdeen, Dr. Kelly will terminate his engagement with the parish council on 15th May next, I am to say that while the Board recognise that this is a matter in the discretion of the parish council, they do not consider that this system is one which should be encouraged, and they trust that the parish council will take a convenient opportunity of re-considering it.

Aberdeen School Board and the Treatment of Unclean Children.

At a conference, held on May 11th, between the public health committee of the Aberdeen town council and a sub-committee of the school board, a memorandum submitted by Dr. G. Rose, medical officer to the school board, was discussed, dealing with the treatment of such infectious diseases as itch, ringworm, impetigo, and vermin on the head and body, which, it was pointed out, were of common occurrence in the schools of the city and injurious not only to the children themselves but to the health of the community. The memorandum pointed out that in order to stamp out these diseases the coöperation and aid of the sanitary authority would be required. Vermin, it was stated, were to be found in the heads of children in all the schools. These cases could quite well be treated at home according to advice given by the medical officers. Children who were allowed to remain unclean after the parents had been warned should be handed over to the sanitary authority to be dealt with. Cases of impetigo should be kept from school for two weeks. Cases of ringworm should, if possible, be made to secure the application of X rays. Itch and verminous cases occurred in practically all the schools. Owing to the lack of a change of bed- and body-clothes it was practically impossible for those suffering from these diseases among the poor to get rid of them without outside help. Here the help of the sanitary authority was imperative, for although the duty of cleaning children was laid upon the board, according to the Public Health Acts of 1897 and 1907, the responsibility of dealing with the other affected members of the family and with their home and surroundings rested on the sanitary authority, and it alone could deal with those. It would be in the interest of the community, therefore, that it should undertake the cleaning and disinfecting of the children also. Multiplying of the sanitary staff and duplication of disinfecting appliances would be avoided, and the medical staff of the board could devote its attention to medical inspection without risk of entering the field or of overlapping the work of others. After discussion, it was agreed to secure information as to what was being done in the large centres before taking any steps.

May 16th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The National University of Ireland.

AT a meeting of the executive committee of the Gaelic League, held recently, a resolution was adopted expressing grave dissatisfaction with the action of the Senate of the National University in ignoring the demand that Irish be made an essential subject for matriculation.

Belfast Asylum.

At the monthly meeting of the Belfast Asylum committee, held on May 9th, a resolution was moved to consider the advisability of completing the whole scheme of new asylum buildings at Purdysburn, by the erection of such additional villas as will accommodate the patients remaining at Grosvenor-road Asylum, and such other buildings as are necessary. The motion, after having been seconded, had to be withdrawn, as so many members of the committee expressed the view that, as the corporation had already sanctioned the raising of from £80,000 to £85,000 for going on with the absolutely necessary part of the work, they really could not ask for more financial help at present. The feeling is growing in Belfast that the asylum is really costing an immense sum of money, and that many other equally pressing municipal health projects are being kept back owing to the enormous sums that are being spent in putting up costly buildings at Purdysburn.

Benn Ulster Eye, Ear, and Throat Hospital.

At the annual meeting of the supporters of this charity, held on April 26th, it was reported that in the extern department 2607 new patients were treated during the past year. There were 39 operations for senile cataract. Since the hospital was founded—about 40 years ago—over 1600 persons have had cataracts removed from their eyes, with restoration of useful vision in well over 90 per cent. of the cases. 256 operations were done during 1909, mostly under general anæsthesia, besides a large number of minor ones under local anæsthesia.

May 17th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

International Conference for the Study of Cancer.

THE Second International Conference for the Study of Cancer will be held at the Faculty of Medicine in Paris from Oct. 1st to 5th. The subscription will be 25 francs, and only members of societies or committees affiliated to the International Society will have an opportunity of taking part in the proceedings. Intimations of intention to be present will be received by the national committee in each country, and will be sent for all countries indiscriminately to the treasurer of the French association. With respect to the official languages, the Conference will follow the principles adopted by the international congresses. The principal business will be the reading of a series of reports devoted exclusively to progress made in recent years, especially since 1906, and to an account of the present state of the various questions under review. These reports will be printed and sent to all the members before the Conference meets. The manuscripts must not make more than 15 octavo printed pages and must be sent before August 15th either to Professor G. Meyer, general secretary of the International Association, 13, Bendlerstrasse, Berlin, or to Professor Pierre Delbet, general secretary of the French Association, 24, Rue du Bac, Paris; those arriving after this date will not be able to appear among the publications of the Conference. The time allowance will be 15 minutes for the reading of each report and five minutes for criticism or remarks during the discussion of the reports, but the President may allow a prolongation of five minutes. Members of the Conference who wish to take part in the discussion of the reports must give notice of their intention to the secretaries of their respective national committees.

The Zambaco Pasha Prizes.

Dr. Zambaco Pasha has recently founded three prizes, one of 1000 francs and two of 500 francs, in connexion with the Society of Tropical Medicine and Hygiene. They will be awarded to the three best memoirs on the contagiousness of leprosy, containing personal investigations and minute and careful scientific observations made on the spot. The committee for awarding the Zambaco Pasha prizes has decided that the candidates shall deal with the following questions: 1. Is leprosy hereditary? 2. Is leprosy contagious from one person to another? 3. Is leprosy communicable to the lower animals? The memoirs shall be accompanied when necessary by illustrative specimens, such as microscopical preparations and photographs. They must be in the French language and must be sent to the general secretary of the Society of Tropical Medicine and Hygiene, 18 Rue de Grenelle, Paris, before April 1st, 1912.

Lunacy Commissioners at the Ministry of the Interior.

A decree of Feb. 2nd, 1910, has established at the Ministry of the Interior a special commission which will advise on all questions concerning the engagement, promotion, discipline, and remuneration of the officials of the public lunatic asylums, as well as on all subjects which may be referred to it either by the Minister or by the director of the Assistance Publique or by the department of public health. The commission consists of seven members, of whom three are medical directors or principal medical officers, elected annually by their colleagues, who have, moreover, to elect a deputy. In questions of discipline affecting assistant medical officers the three medical directors or principal medical officers will be replaced by an equal number of assistant medical officers.

Société Nationale du Chien Sanitaire.

In France, as in other countries, there exists a Société Nationale du Chien Sanitaire for training dogs to find the dead and wounded on the battlefield. The French society held its general meeting in Paris on April 30th at the Mairie of the Eighth Arrondissement. The President said that the membership had almost doubled since last year, during which the society also took part in the dog show in Paris. During 1910 the society will be represented at various shows and exhibitions, as well as at courses of instruction in connexion with the *service de santé* in Paris and at rehearsals of finding wounded soldiers both by night and day. At the request of the Association of French Ladies, a demonstration will be given before long at Auteuil. M. Laval has been appointed to collect information with respect to this class of trained dogs in various countries, and at the next general meeting M. Grandjux will open a discussion on the question, Who ought to provide the necessary supply of these dogs for the army in time of mobilisation?

Traumatic Osteoma.

At a meeting of the Paris Society of Medicine held on May 13th, M. Dabout showed a patient upon whom he had operated for a traumatic intramuscular osteoma in the right vastus externus. At the same time he showed the tumour and radiographs bearing on the case, the disease being consecutive to the kick of a horse. M. Dabout laid great stress upon the length of time the tumour had taken to develop, for a radiograph taken some six weeks after the accident was quite negative. M. Caudray said that the periosteal origin of osteomas had given way to the theory that they were due to a myopathy, except in the case of osteomata growing near the articulations or where they were obviously due to some periosteal condition.

May 17th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Infantile Tuberculosis in Vienna.

Dr. Pollak, speaking before the Medical Society of Vienna, gave the results of investigations which he had made into the clinical and pathological details of tuberculosis amongst infants. He has seen 92 cases of undoubted disease within one year, of which 86 gave a positive tuberculin reaction and 6 were seen at the necropsy. 30 cases were diagnosed in the first year of life, 62 in the second year. The youngest infant was 39 days old when the diagnosis was made. The prevalent symptoms were those of tuberculosis of the bronchial glands, such as cough and expiratory râles; in 22 cases cutaneous tuberculides were present. In 17 cases tuberculous meningitis was observed, and Dr. Pollak believed that it was mostly a fresh infection on account of the absence of affections of the bronchial glands and the existence of good general health at the onset. In three cases there was nothing to indicate tuberculosis, except the fact that in spite of breast-feeding the infants became pale and lost flesh. The tuberculin reaction explained matters at once; wherefore it was very important, according to Dr. Pollak, to apply this test in similar cases. Until quite recently the prognosis of infantile tuberculosis was thought to be very bad, but it had now been found that this was not so. Of the 92 children kept under observation 42 were still alive (in the first, second, and third year of their age), whilst the rest had died. The mortality of the infants who were found diseased in their first half-year was 87 per cent., while for those who were attacked in the second half-year it was 58 per cent. The age at infection was therefore very important. The severity of the disease was proportionate to the severity of the disease in the person who infected the infant, and the prognosis was the better the more carefully the child was nursed. Breast-feeding was not absolutely essential, 30 per cent. of the survivors having been fed by hand from bottles. The surviving infants showed a complex of symptoms which was characteristic—the so-called tuberculous habitus, which developed many months after infection, as the infected infant might appear healthy for a considerable period. Dr. Pollak had examined all children who had come in contact with one of his tuberculous patients, and who had therefore lived in tuberculous surroundings. Of 200 children living under these conditions, only nine did not react to tuberculin in a dose of 1 milligramme injected subcutaneously, a circumstance which was to be explained either by an absence of infective agency or by a minimal degree of infection. The investigations conducted in a very searching way had brought to light the fact that all children who had become infected were under four years old, whilst those above four years of age nearly always escaped. Of 243 children, all those became infected in whose case either one parent or both parents were infected at the time when the children were born, but if the infection carrier did not become ill till after being married several years the older children remained free. Dr. Pollak believed that older children acquired a sort of immunity against tuberculosis ("Tuberculose-Festigkeit"), and he said that the "habitus phthisicus" indicated that the child had been infected in his first years of life, whilst tuberculous manifestations in older children were survivals of an infection contracted in very early life. Of course, these conclusions require a much larger series of observations before being accepted as convincing.

The Comparative Chemistry of Brain Substance.

Dr. Linnert, at a recent meeting of the Gesellschaft der Aerzte, read a paper in which he gave some interesting details on the chemistry of the brain. He said that the lipoids formed the main bulk of the brain. Analysis showed that they consisted of the elementary substances oxygen, hydrogen, nitrogen, carbon, and phosphorus, with some sulphur. The brain of the higher animals was fairly constant in its composition; the quantity of the brain increased with the bulk of the body, the dry substance and the lipoids being mainly responsible for this increase in weight; the human brain contained more lipoids than any other brain. The cortex contained more water than the white substance; the dry substance of the cortex had 45 per cent. of lipoids, the white substance 75 per cent.; the latter had also less phosphatides, whilst the pons and the medulla had the largest proportion of water in the whole brain. The cerebellum contained much water, but only a small proportion of lipoids and phosphatides. The spinal cord was poorer in water than the brain; its dry substance might contain as much as 80 per cent. of lipoids, whilst the entire brain had 60 per cent. of its weight in lipoids.

Taxation of Medical Practitioners.

A report recently issued by the Revenue Office gives some interesting particulars relative to the rates and taxes payable by Austrian medical practitioners, and the following figures are worth recording. The doctor in this country has to pay first the so-called occupation-tax (*Erwerbsteuer*), which is assessed according to the locality, the extent of the district, and the quality of practice under consideration. The minimum tax is levied on beginners and amounts to about 8*s*. a year, but it soon increases, and the average amount is about ten times that sum, whilst of course in cities the figures go up to £40 or £50 a year, especially with specialists of repute. The amount paid under this heading by medical men in Vienna is about £16,000. In the next place, a practitioner has to pay income-tax. He has to show how much of his income is derived from his medical practice and how much from other sources. The proceeds of practice are taxed so that annual incomes up to £125 pay 1 per cent. and those from £125 to £250 pay 1½ per cent., whilst for every additional £80 of income an additional ¼ per cent. (approximately) has to be paid. The maximum is reached with a tax of 5 per cent. on a practice of £2000. The amount thus paid by medical men in Vienna reaches

£26,000. It can hardly be said that these figures allow any positive conclusions to be drawn as to the actual amount of the income of the medical profession in this city, but it may nevertheless be remarked that the income-tax is equivalent to about £800,000 earned by the medical men. The average amount paid by a practitioner in this city in the shape of rates and taxes is from 3 to 4 per cent. of his earnings. Incomes derived from appointments, as well as those of officers of public health, are taxed only on the sliding scale of the income-tax, no occupation-tax being payable on account of them.

Introductory Lecture by Professor Wertheim.

Professor Wertheim, the newly-appointed director of the Second Gynæcological and Obstetrical Clinic, opened the summer session of his clinical course by a short introductory lecture, which was attended by many professors, by the whole Senate of the Medical Faculty, and by numerous students. After a sympathetic allusion to the career of Professor von Rosthorn, his predecessor, Professor Wertheim explained his attitude to the problems of modern gynæcology and obstetrics. He considered that caution and patience were qualities indispensable to an obstetrician, emphasised the overwhelming importance of asepsis in obstetrics, especially when midwives were in attendance on the patient, and spoke of the necessity of expertness in performing operations and making a diagnosis. As regards gynæcology, he said that for any success to be obtained in cases of cancer radical and surgical treatment must be commenced as early as possible. He also cited some examples of the mutual relations existing between general medicine and his specialty, and advised the students to pay close attention to these relations.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENT.)

A Commission on Public Safety.

A PLAN has been put forward in Minnesota for the formation of a State Commission on Public Safety. It is suggested that this body, which it is proposed should sit all the year through, should take over all the functions now exercised by the Board of Health, the administration of the pure-food laws, the work of the Bureau of Labour, and of all other departments of the public service whose object is to safeguard life, limb, and health. The originator of the plan is Dr. Henry M. Bracken, secretary of the Minnesota State Board of Health.

Cancer Research.

Cancer research in the United States will be benefited by the munificence of Mr. George D. Barnard of St. Louis, who has provided the funds for a new four-storey hospital building, to be shortly opened for the St. Louis Skin and Cancer Hospital, which was founded by the same generous donor in 1906. The entire fourth floor of the new buildings will be reserved for a research laboratory, which is to be fully equipped for cancer research, and the sum of $8000 has been set aside for that purpose. Professor Leo Loeb, of the University of Pennsylvania, has been selected as director of the new laboratory. Since the foundation of the St. Louis Skin and Cancer Hospital four years ago much good work has been done in the institution, which, unlike most hospitals in this country, is a purely charitable institution, having neither pay wards nor pay beds. Efforts are being made to raise a much larger endowment fund to ensure the permanence of this work.

A Life Insurance Company Aids the Attending Physician.

A novel departure has been made by the Metropolitan Life Insurance Company of Philadelphia. This company has entered into an arrangement with the District Visiting Nurse Society of the city to supply nurses—for night service where necessary as well as for day—to visit its sick policy-holders, irrespective of the amount of their insurance or of any other considerations, in coöperation with the attending physicians. By seeing that his orders are carried out, and by obviating those difficulties that so frequently arise from ignorance or negligence, the company believes that its own interests, as well as those of the policy-holding patient, will be preserved. The move is admittedly a pure business proposition.

The Sanitary Condition of the Isthmus of Panama.

Probably no document ever issued showed so conclusively the beneficial results of intelligent sanitary administration as the recently published report of the Department of Sanitation of the Isthmian Canal Commission for 1909. In 1906 the general death-rate was 41·73, in 1907 28·74, in 1908 13·01, and in 1909 10·64, in spite of the fact that there were 47,167 employees in 1909, as against 26,547 in 1906. The typhoid death-rate for the year was only 0·27 per 1000. The deaths from malaria—that erstwhile scourge of the country—were only 52. Not a single case of yellow fever, small-pox, or bubonic plague occurred. When the frightful conditions in regard to disease that formerly made the region a veritable death-trap and caused the failure of the French canal project are recalled, the result is surely a most convincing testimony to the value of scientific sanitation.

Death of Dr. F. Byron Robinson.

Dr. F. Byron Robinson of Chicago, who died recently at the age of 53 years, was a most tireless worker as an anatomist, investigator, and teacher, and a prolific writer on many subjects. He was also an accomplished surgeon in the field of intestinal and gynæcological surgery. He had held many teaching posts, and was held in the highest regard by all his old pupils, who were very numerous, as well as by a wide circle of professional friends.

May 9th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Reorganisation of the St. John Ambulance Association in India.

A MEMORANDUM has recently been issued by the executive committee of the Indian branch of the St. John Ambulance Association regarding the extension of the sphere of usefulness of the branch. The Viceroy as president takes a deep personal interest in the matter, and the idea is that "the time has come when the active support of the heads of local governments, of the rulers of Indian States, and of the leaders of non-official organisations, industrial and commercial, is essential to secure the desired expansion and to place the working of the association on a sound and permanent footing." The committee has accordingly invited the various authorities and associations indicated above to coöperate in the matter and to take the initiative in provinces, states, and large towns with a view to carrying out the new scheme. Individuals in India are liable to sudden transfers, and to place the organisation of the association on a sound basis it has been deemed desirable that the local authorities and heads of the community should become *ex-officio* the local leaders of the association, instead of leaving it entirely to the individual efforts of private persons whose transfer may cause centres practically to cease to exist. In England and the Colonies a fee similar to that levied by other educational bodies is charged by the association for holding examinations under its auspices. As a special concession to the peculiar needs of India this fee need not necessarily be charged, and a charge of six annas (sixpence) for each certificate to cover the cost of printing, examiner's report form, registration, &c., is the only charge made in addition to the cost of books and appliances. The cost involved is, therefore, not very great, as 250 persons can be certificated for about Rs.100 (£6 13*s.* 4*d.*). The certificates are in the form approved by His Royal Highness the President of the association. They are sent out in bulk from London and are issued from the stores depôt, Bombay, on receipt of an attendance register and examiner's report on the prescribed forms. Information with reference to the formation of classes is laid down in pp. 16–19 of the pamphlet "The St. John Ambulance Association in India." Lecturers should as a rule be commissioned medical officers or fully qualified medical men or women, but where circumstances render it desirable military or civil assistant surgeons, hospital assistants, or certified practitioners may be appointed. Any person qualified to lecture may also examine classes, but examiners should as a rule be detailed by district secretaries and no lecturer can in any circumstances examine his own class. One of the main objects of the branch is to place the

local organisations of the association on a really sound footing and ensure their steady growth. With this view it is hoped in the future to appoint a whole-time secretary who will visit local bodies at regular intervals and devote his whole energies to furthering the association's efforts. The following shields and cups have been presented for competition amongst ambulance workers in India—viz., (1) Indian Volunteers' Challenge Shield presented by His Royal Highness the Prince of Wales; (2) Indian Railways Challenge Shield presented by His Royal Highness the Grand Prior and the Chapter of the Order of St. John; (3) the St. John Ambulance Brigade Challenge Cup; (4) the Bombay Police Challenge Cup; (5) the Oudh and Rohdkhand Railway Inter-Station Challenge Shield; and (6) the North-West Frontier Police Challenge Cup. Full particulars of the conditions under which these cups are held are issued annually to all concerned and may be obtained at any time from the honorary secretary, Indian Branch. The association is one which should command the full support of the Europeans and Indian communities, and there should be a satisfactory response to the memorandum issued by Colonel W. R. Crooke-Lawless, C.I.E., secretary of the executive committee of the Indian branch.

April 16th.

NOTES FROM CHINA.

(FROM OUR OWN CORRESPONDENT.)

The Helminths of China.

I HAVE previously referred to this subject, but the issue of a new report by the Research Committee of the China Medical Missionary Association in its journal warrants a further notice, if only from the importance given to it by the extraordinary number of persons affected by helminthiasis in China. To such an extent is this the case that a preliminary dose of calomel and santonin is almost a routine practice in the hospital treatment of all cases. At the same time, notwithstanding the high percentage of infections, it must be admitted, taken all round, that the part played by worms in the causation of intestinal disease is a comparatively minor one. As far as China is concerned, the suggestion of M. Metchnikoff that intestinal worms are extensively involved in the etiology of appendicitis may be regarded as incorrect, for this disease is one of the rarest surgical affections throughout the Empire. It has been said that worms are carriers of bacterial and coccic infection, externally by being covered with microbes, and internally by their intestinal microbic flora. This, however, is a danger which counts for little here, for while it is literally true that over 65 per cent. of the population of China harbour worms of one kind or another, there are not many who show signs clinically of the parasites they support. Although such parasites cause lesions of the intestinal mucosa, the damage done is probably not more than can be dealt with by local phagocytosis. Certain it is that healthy coolies are brought into hospital for street accidents, &c., who are daily passing millions of ascaris ova without being aware of anything wrong intestinally. (The mention of these men tempts me to add a note of the very expressive Chinese term used to describe their calling. They are called "*Mai li ch'i-ti jen*"—i.e., sellers of strength.) Having regard to the high prevalence of worms throughout China, it was felt by the Medical Missionary Association that a combined effort should be made to arrive at a more definite knowledge of the subject, and to further observe the geographical distribution and form a more reliable basis for future additions and corrections. The following data are from the last report and they are the outcome of widespread observation, the reports being drawn from all over China from tropical to subarctic zones. They were presented under the headings of each province, but to save space I have summarised them. 1. *Ascaris lumbricoides:* 75 per cent. of infections; no clinical manifestations except occasionally in children. Sometimes, though rarely, it is migratory—e.g., a case of multiple sinuses of the thigh in which an ascaris appeared in one of the openings, and in another case in a sinus under the twelfth rib. Among young Chinese ascaris is practically universal, but infection often apparently dies out of itself. It is equally common all over China, Manchuria, Korea and Siam. 2 *Ankylostomum duodenale:* About 40 per cent. of infections; very often no clinical indication. In one careful report less than a third of those infected showed anæmia and a hæmoglobin percentage of 65 or less; often no degree of anæmia was demonstrable. Sometimes there is mixed infection of A. duodenale and Necator americanus. The parasite is overwhelmingly preponderant among the farming class as compared with town dwellers. In the former there are often cases of ground itch, but vast numbers suffer who show no signs of skin lesions. This parasite is almost absent in North China. 3. *Strongyloides intestinalis* (syn., *Anguillula stercoralis*): Scarcely 1 per cent. of infections; in Mid and South China. In one case, a double infection, it was found along with large numbers of ankylostomum ova, where the strongyloid embryos in a fresh stool were seen swimming about among unsegmented ankylostomum ova. 4. *Trichocephalus dispar:* Common, about 18 per cent. of infections from Shanghai southward; no discomfort in human host. 5. *Oxyuris vermicularis:* 0·5 per cent. of infections. Though common in other countries it is noted as rare in China, with the exception of the province of Shantung, where it is reported as extremely common. 6. *Schistosomum japonicum:* 7 per cent. of infections. A point of much practical interest noted by Dr. Houghton of Wuhu, is that "in a number of the cases no history was obtained which would point to the harbouring of such a parasite, and physical examination was negative; other cases gave a history of obscure gastric trouble, and physical examination gave no clue to the real situation." From all accounts it would appear that the distribution of this worm is almost entirely limited to the Yangtze Valley. The clinical picture associated with the parasite is usually that of dysentery with accompanying anæmia, ascites, and enlarged liver and spleen. 7. *Clonorchis* (*Opisthorchis*) *sinensis:* Occurs in from 4 to 7 per cent. of infections in Hong-Kong and South China, to which its distribution seems limited, as there is only one case reported from Hankow, which was probably imported; otherwise it is not seen in the human host in the Yangtze Valley, though it has been noted as not uncommon in cats. It is also present in Siam and Korea. 8. *Fasciolopsis buskii* (*Distomum crassum*), a fluke of much pathological importance: Is endemic in Ningpo, Swatow, Canton, and Hong-Kong. In Shanghai it occurs in 0·4 per cent. of infections. It has never been observed in North China. Fasciolopsis goddardi is reported as having been met with in the Yangtze Valley. 9. *Paragominus* (*Distomum*) *westermani:* Has been found in Hong-Kong, but probably only from infected cases. 10. *Tænia:* Cestode infection in man is admittedly unusual in China. It has been definitely stated by several practised observers to be absent in South China and only very rarely is noted in other parts of the Empire. An interesting point occurs in a report from Tsingtau, the German settlement on the north-east coast, and as it shows in a striking way the affinity of certain worms for European or Chinese human hosts habituated to different modes of life and diet, I give the figures which were collected by Dr. Uthemann, head of the German Government Medical Staff:—

	Europeans.	Chinese.
Eingeweide würmer	119	—
Ascaris lumbricoides	126	366
Oxyuris vermicularis	1	1
Tænia (allgemein)	209	—
,, saginata	28	—
,, solium	13	—
,, echinococcus	1	2
Amœba coli	39	—
Lamblia intestinalis	1	—

Cestode larvæ have been observed by Dr. Houghton in fish in abundance and bothriocephalus latus is frequent in cats, but he could not find traces in a human host. It is difficult to account for the freedom of Chinese from cestodes; probably there is much in attributing it to the fact that the Chinese eat their beef and pork thoroughly cooked and chopped in small pieces. The meat is never served cooked in joints. I have seen a case of bilharzia hæmatobium in a British soldier in Peking. He had previously suffered from it in South Africa. But no instances have been met with in which Chinese suffered from this Ethiopic fluke. These notes are the outcome of widespread observation from provinces differing greatly in climate, elevation, density of population, and amount of rainfall. But, in the absence of sewerage systems, the unclean habits of

the people, and the spreading of night soil over vegetables, these provinces have all the same sources of infection.

Munificent Gifts.

News has been received in Shanghai that the well-known firm of Krupp has made the handsome donation of half a million marks, or £25,000, to the German Medical School at Shanghai. In this school the teaching is in German, and in addition to their regular medical course they give the necessary preliminary training.—Mr. H. S. Wellcome has contributed £1000 to found a perpetual publishing fund for the translation of leading medical works into Chinese, under the control of the China Medical Missionary Association.

April 20th.

Obituary.

HERBERT NELSON CAPPE, M.R.C.S. ENG., L.R.C.P. LOND.

THE Surrey county council has lost a reliable officer, and all who knew him a sincere friend, in the untimely death of Herbert Nelson Cappe on April 22nd, aged 44 years. He was the only son of Mr. Walter Cappe, who was appointed clerk and steward of Brookwood Asylum when it was completed in 1867.

Educated for the medical profession at University College Hospital, he qualified in 1888, and immediately acted as locum tenent at the asylum for three months. For a short time thereafter he went into private practice, but returned to Brookwood as junior medical officer 16 years ago, being appointed to the senior position on Dr. F. C. Gayton leaving to take charge of the new asylum at Netherne late in 1908. The circumstances of his death were peculiarly sad, as within a short time he had every reason to believe that he would have realised his ambition and have been appointed medical superintendent at the place where the greater part of his life had been spent, but while conducting a post-mortem examination he became infected, and after a gallant struggle for a month, and in spite of everything that could be done for him, he passed away. The cause of death was septicæmia. Always painstaking and conscientious in the performance of his duties, an able physician and an agreeable colleague, his loss will long be felt by both the staff and patients of the asylum.

A good all-round sportsman, Mr. Cappe was well known outside the precincts of Brookwood as a cricketer. For the Brookwood Asylum team, whose cricket ground is one of the finest and best kept in the county, he made many long scores.

CESARE ZONCHELLO.

THE "Martyrology of Medicine" has just been enriched by another chapter, in the untimely death of this able, accomplished, and intrepid bacteriologist, who "died at his post" at Jeddah on the Red Sea on April 17th.

Born 33 years ago at Sedilo, in the Island of Sardinia, the son of an esteemed medical practitioner still actively engaged in professional work, Cesare Zonchello was one of seven brothers, two of them distinguished at the Bar, a third in the navy, a fourth in commerce, and the remaining two still under their father's eye. A student in arts and medicine at the University of Cagliari, Cesare Zonchello graduated with honours in the latter faculty, and was, for three years thereafter, absorbed in rural practice. Valuable as was the experience thus acquired, he longed to supplement it in other fields, and, after a survey of the several departments of medicine, found himself especially drawn to bacteriology in its practical applications. For the next two years accordingly he studied under Professor Angelo Celli at Rome in the "Istituto Nazionale d'Igiene," and speedily took rank as one of the most proficient *alumni* of that master. In 1906 the Ottoman Government, with a view to strengthening its sanitary administration, threw open to competition an important post in that service. Cesare Zonchello became one of the "concorrenti" and came out at the head of the list, with an immediate destination to the lazzaretto of Camaran in the Yemen.[1] That island is about the least attractive of its treeless, sandy congeners, dotted with some six or seven villages, and possessing a harbour periodically visited by the steamers which convey hordes of pilgrims to Mecca. The said "hordes" arrive from beyond the Straits of Bab-el-Mandeb, from the Persian Gulf, from India, from Java, from the Mahommedan Orient in general, and are compelled by law to undergo seven days' sanitary surveillance at Camaran. All passengers suffering, or suspected of suffering, from plague, cholera, small-pox, or other maladies, infective or contagious, are detained and put under treatment till cured. Those who are in certified good health continue their voyage to Jeddah, whence they proceed on foot to Mecca. For six months the island is alive with these pilgrims, as they come, stay their appointed time, and start again; and for another six months it relapses into the silence and the squalor which form its external features. Dr. Zonchello had taken part in three of these "campaigns," as the recurring periods of six months are called, having two compatriots among the 11 colleagues deputed by the other European Powers, Dr. Delpino, director of the staff, and Dr. Businelli of Milan, since dead. Distinguished among them for his ardour in bacterial research, he had utilised his opportunities in an elaborate series of dissections of rodents and in the cultures made from them, till on April 17th he succumbed to that misadventure, all too common in his *métier*, blood poisoning contracted from a puncture.

A compatriot describes him as a fine robust specimen of the Sardinian islander, full of *bonhomie* and fervour, moral and intellectual, passionately fond of work, and relieving it, at intervals, in letters to his family and friends, whom he kept *au courant* with his studies and findings. Writing from Cagliari on May 10th, 1909, he says: "I am here for two months preparing for a spell of cholera research at Jeddah and collecting all the requisite equipment. The next 'campaign' of 18 months will find me there employed on a steady, accurate investigation of the plague. When I read in the newspapers of the tumults and revolutionary surprises in Turkey, I seem to think we shall be living in the neighbourhood of a powder magazine which from one hour to another may blow us sky-high." Nominated sanitary director of the lazzaretto of Abou-Saad, near Jeddah, where the pilgrims on their return from Mecca are once more subjected to examination, he found the work still more arduous, the infected cases still more numerous, owing to the fatigues of the double voyage, its excitement and privations. Abou-Saad, moreover, was not nearly so well provided with laboratory and clinical resources as Camaran, and the risks encountered by the medical staff were at once greater and less easy to combat. Notwithstanding these adverse conditions, he struggled bravely and cheerily at his post, but with all too visible deterioration of health and resisting power, until at Jeddah, as already stated, he fell a victim to duty, literally dying at his post.

[1] THE LANCET, vol. i., 1907, pp. 1251, &c.

HENRY JAMES SMYTH, L.R.C.P. LOND., M.R.C.S. ENG.

Mr. H. J. Smyth died at his residence, South Molton, Devon, on April 27th, from pneumonia, following influenza, after a short illness. The deceased, who was 49 years of age, received his medical education at St. Thomas's Hospital, and qualified L.R.C.P. Lond. and M.R.C.S. Eng. in 1886. After holding resident appointments at St. Thomas's Hospital Mr. Smyth commenced practice at South Molton. Among other appointments he held those of medical officer and public vaccinator for the Fourth and Eleventh Districts of the South Molton Union, surgeon to the Great Western Railway employees, and medical officer to the Post Office. Mr. Smyth was highly esteemed in South Molton, where he had resided for 20 years; he took great interest in local matters, and he will be greatly missed there. He leaves five sisters for whom much sympathy is felt. The funeral, which took place on May 1st, was largely attended. At the service the vicar made feeling allusion to the deceased and the great loss which the town had sustained by his death.

EDWARD CRESSWELL BABER, M.B. LOND., M.R.C.S. ENG., L.R.C.P. LOND.

THE death of Dr. Edward Cresswell Baber occurred at his London residence in Brook-street, Grosvenor-square, on May 14th. Well known in London, he was perhaps better known in Brighton and Hove, where he had a house, and the news of his death at the comparatively early age of 59 years

came as a great blow to very many. The medical charities of these latter towns have lost a great friend, particularly the Brighton and Sussex Throat and Ear Hospital, of which he was senior surgeon. The son of the late Dr. John Baber of South Kensington, he was educated at King's College School, London, and commenced his medical career at St. George's Hospital, where he was a prize-winner and William Brown scholar. He subsequently became house surgeon and demonstrator of anatomy. He continued his medical studies in Paris and Vienna. In the course of his career, Dr. Baber had been President of the Laryngological Society of London, Vice-President of the Otological Society, honorary secretary of the International Otological Congress in 1899 and President in 1909, President of the Section of Laryngology and Otology, British Medical Association, 1899, and President of the Brighton and Sussex Medico-Chirurgical Society. He had also been resident medical officer at the Atkinson-Morley Convalescent Hospital and surgeon at the Royal Ear Hospital, London. In spite of the many calls upon his time, Dr. Baber was a frequent contributor to medical journals on the subject of diseases of the ear, nose, and throat, and contributed to THE LANCET an important "Report of 100 Cases of Ear Disease." He was also the author of a valuable guide to the examination of the nose, and of two contributions to the Philosophical Transactions of the Royal Society of London on the anatomy of the thyroid gland. The funeral took place at Hove Cemetery on May 18th, the interment being preceded by a service at St. Anselm's Church, Davies-street, London.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Buschbeck, president of the Dresden Medical Society.—Dr. Heinrich Kempner, one of the oldest members of the medical profession in Germany, being in his ninety-first year. He had been living in retirement at Breslau for the last 20 years.—Dr. Oscar C. De Wolf, formerly professor of hygiene in the Northwestern University Medical School, Chicago.—Professor Hermann Lenhartz, director of the Eppendorf Hospital, near Hamburg, and one of the most eminent physicians in Germany. He studied in Leipsic and was for several years assistant to Professor Ernst Leberect Wagner there and became extraordinary professor. In 1895 he was appointed director of St. George's Hospital, Hamburg, and some years later director of the great Eppendorf Hospital. He was recognised as an authority in everything connected with hospital management, and was president of several committees, such as those for cancer research and Red Cross organisation. He published monographs on lumbar puncture and gastric ulcer and contributed to encyclopædic works, including those of Nothnagel and Ebstein. A very important work of his on the microscopy and chemistry of the puerperal period has gone through five editions. His death appears to have been quite unexpected. His age was 56 years.

NATIVE RACES AND THE LIQUOR TRAFFIC.—The United Committee for the Prevention of the Demoralisation of Native Races by the Liquor Traffic, which regrets that "in nearly every part of the world where missionaries are at work the gin bottle is present, also making the natural difficulties of the work much greater and sometimes undoing good that has been achieved at great sacrifice," has issued a grave indictment against the Government Committee of Inquiry with regard to the liquor traffic in Southern Nigeria. In a pamphlet entitled "An Examination and Reply," the Native Races Committee accuses the Government Committee of ignoring a statement prepared by the Native Races Committee, asserts that influences were at work in the colony calculated to deter the natives from speaking against the liquor traffic, and suggests that the Government Committee was biased. The pamphlet also states that the importation of spirits in Southern Nigeria is steadily and rapidly increasing, the result being much drunkenness, that gin is used as a form of currency, that fines have been paid in gin in six courts for a long period, and that the fact that children are pawned for gin throughout the colony is absolutely ignored by the committee in its report. The publication of these grave statements by a responsible committee, which has for its president the Duke of Westminster and for its chairman the Bishop of London, calls for some rejoinder.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At a meeting of the Comitia of the Royal College of Physicians and of the Council of the Royal College of Surgeons on April 28th and May 12th respectively, Diplomas of L.R.C.P. and M.R.C.S. were conferred upon the under-mentioned gentlemen and one lady (Miss D. R. C. Patell, of Bombay, the first lady to obtain these diplomas) who have passed the Final Examination in Medicine, Surgery, and Midwifery, and have complied with the necessary by-laws:—

Oswald John William Adamson, King's College Hospital; Fleetwood Stirling Digby Berry, Guy's Hospital; Noel William Berry, King's College and St. George's Hospitals; David Forbes Borrie, New Zealand and Edinburgh Universities; Robert Francis Bridges, B.A. Oxon., Oxford University and London Hospital; Leonard Buckley, M.B., Ch.B. Liverp., Liverpool University; John Southerden Burn, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Ronald Herbert Candy, London Hospital; *Noel Leicester Clarke, B.A. Cantab., Cambridge University and London Hospital; William Thomas Clarke, Bristol University and Guy's Hospital; Frederick John Cleminson, M.A., B.C. Cantab., Cambridge University and University College Hospital; Reginald Charles Clifford, St. Bartholomew's Hospital; Ardeshir Koyaji Contractor, L.M.S. Bombay, Bombay University and University College Hospital; William Russell Cooper, Glasgow University and University College Hospital; Donald Maxwell Cox, Charing Cross Hospital; Rustom Kershasp Dadachanji, L.M.S. Bombay, Bombay University and London Hospital; Ralph George Dainty, Charing Cross Hospital; William Chalmers Dale, St. Bartholomew's Hospital; Cecil Alfred Dottridge, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Henzell Howard Dummere, London Hospital; Geoffrey Dunderdale, Guy's Hospital; William Alexander Dunn, Otago University and St. Thomas's Hospital; William Harold Fulford Eales, Cambridge University, Middlesex Hospital, and Birmingham University; Samuel James Elkin, M.D., C.M. Manitoba, Manitoba University and London Hospital; Robert Ellis, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Joseph Tylor Fox, B.A. Cantab., Cambridge University and London Hospital; Frank Austin French, St. Mary's Hospital; Lennard Game, King's College Hospital; Raymond Gamlin, Cambridge and Liverpool Universities; Robert William Beor Gibson, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Cyril Searle Gideon, M.B. Toronto, Toronto University and London Hospital; Philip Hamill, M.A. Cantab., D.Sc. Lond., Cambridge University and St. Bartholomew's Hospital; Joseph Cecil Harris, L.D.S. Eng., Birmingham University; Robert Francis Higgin, B.A. Cantab., Cambridge University and Middlesex Hospital; Arthur Noel Hodges, B.A. Cantab., Cambridge University and London Hospital; Ernest Howden, Leeds University; Stanley Hoyte, King's College and Westminster Hospitals; Herbert Richard Barnes Hull, Bristol University; Robert Ashton Jackson, M.B., Ch.B. Manchester, Manchester University; Roderick Jackson, Liverpool University; †Cecil Augustus Joll, M.B., B.S. Lond., L.D.S. Eng., Bristol University; Evan Hugh Jones, St. Thomas's Hospital; Pendrell Charles Varrier Jones, M.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Walter Foulkes Jones, B.A. Cantab., Cambridge University, King's College, and St. George's Hospitals; Fritz Kahlenberg, Otago University and Guy's Hospital; George Gibson Lyttle, M.B., B.S. Lond., National University, Belfast; Mahmoud Foad Maaz, Cairo and London Hospital; Frederick Norton Haylock Maidment, London Hospital; Kenneth Dalrymple Marriner, St. Thomas's Hospital; George Maxted, Guy's Hospital; Archibald Moir, M.B. Toronto, Toronto University and London Hospital; *Andrew Samuel Moorhead, M.B. Toronto, Toronto University and London Hospital; Frederick Morres, Guy's Hospital; George Ernest Neligan, B.A. Oxon., Oxford University and London Hospital; John Henry Newmarch, B.A. Cantab., Cambridge University and St. George's Hospital; Albert Edgar Nicholls, University College, Cardiff, and London Hospital; Henry Maurice Dunlop Nicoll, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Charles Noon, St. Bartholomew's Hospital; Ernest Nuttall, Manchester University; Thomas Edward Osmond, Cambridge University and St. Bartholomew's Hospital; Alexander Croydon Palmer, London Hospital; Dossibai Rustomji Cawasji Patell, L.M.S. Bombay, Bombay University and Royal Free Hospital; Percy Vivian Giles Pedrick, L.D.S. Eng., Guy's Hospital; William Maxwell Penny, Cambridge University and Middlesex Hospital; Archie Perlman, Leeds University; Archibald Bruce Pettigrew, Sheffield University; Friedrich Otto Maximilian Pfister, M.D. Heidelberg, Heidelberg University and Middlesex Hospital; Alfred Percy Phillips, St. Bartholomew's Hospital; Francis Stedman Poole, B.A. Cantab., Cambridge University and Charing Cross Hospital; John Bernard Pulling, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Arthur Errington Rayner, B.A. Cantab., Cambridge University and Guy's Hospital; Norbert Leo Maxwell Reader, Leeds University and Guy's Hospital; Albert Hill Rolph, M.B. Toronto, Toronto University and London Hospital; James Bruce Ronaldson, B.A. Cantab., Cambridge, Dublin, and Edinburgh Universities and Charing Cross Hospital; Johannes Zacharias Human Rousseau, B.A., M.B., Ch.B. Edinburgh, Edinburgh University; Francis Donaldson Saner, Cambridge University and Guy's Hospital; Hassan Ibrahim Shaheen, Cairo and Guy's Hospital; Neville Alexander Dyce Sharp, Guy's Hospital; William Shipton, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Ralph Gillespie Smith, Charing Cross Hospital; Richard William Starkie, Manchester University; Reginald Samuel Sherrard Statham, Bristol University and Westminster Hospital; Thomas Duncan Macgregor Stout, Guy's Hospital; Thomas Edmund Alexander Stowell, St. Thomas's

Hospital; Harold Thwaite, Birmingham University; Cecil Carrington Tudge, Guy's Hospital; *George Ernest Vilvandré, London Hospital; Leslie Ferguson Kennedy Way, St. Bartholomew's Hospital; Charles Witts, Guy's Hospital; Raphael Yood, Manchester University; and Walter Ansley Young, Madras and London Hospital.

* M.R.C.S. Diploma granted on April 14th, 1910.
† L.R.C.P. Diploma not yet conferred.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The Diploma of Fellow has been conferred upon Davis Woodcock Daniels, M.B., B.S. Lond., L.R.C.P., M.R.C.S., of St. Mary's Hospital, who has now attained the age of 25 years.—Licences to practise dentistry were conferred by the Council of the College on May 12th on 35 gentlemen who have passed the requisite examinations and have complied with the by-laws. The following is a list of the names of the successful candidates:—

Henry Kiver Allison, D.D.S. Penn., Pennsylvania University and Royal Dental Hospital; Ernest Beddoes, Liverpool University; Herbert Stuart Blackmore, University College and Royal Dental Hospital; Ernest Benjamin Brown, Middlesex and National Dental Hospitals; Percivale James Burton, Bristol University; William Hern Cornelius, Middlesex and Royal Dental Hospitals; Arthur Josiah Dabbs, Birmingham University; Joseph Henry Creasy Davis, Middlesex and Royal Dental Hospitals; Niel Edgar, Guy's Hospital; James Mutrie Frank, Liverpool University; Herbert Edward Fullerton, Durham, Charing Cross and Royal Dental Hospitals; Harold Harding Glover, Guy's Hospital; Montague Nathaniel Goodman, Charing Cross and Royal Dental Hospitals and Birmingham University; Edwin Allan Thomas Green, Manchester University; Bernard Grellier, Charing Cross and Royal Dental Hospitals; Frank James Hayman, Bristol University; Kenneth George Hoby, Edward Palmer Hudson, and Frank Augustus Lowe, Guy's Hospital; George Bertrand Lucas, Charing Cross and Royal Dental Hospitals; Hubert Stanley Morris, Archie Ernest Frederick Peaty, Alfred Graham Poock, B.A. Cantab., and Augustus John Reynolds, Guy's Hospital; Alexander James Roberts, Birmingham University; Wilfrid Aubrey Rowe, Charing Cross and Royal Dental Hospitals; Charles Frederic Leyson Ruck, Guy's Hospital; Walter Herman Scales, Liverpool University; Alfred Gladstone Scott, Birmingham University; James Bennett Sharp, Charing Cross and Royal Dental Hospitals; John Francis Sheahan, Westminster, Charing Cross, and Royal Dental Hospitals; William Skerritt, Sheffield University; Charles Foote Snow, Guy's Hospital; Claud Stacey, Middlesex and National Dental Hospitals; and Charles Reynolds Woodruff, L.R.C.P., M.R.C.S., St. Bartholomew's and Royal Dental Hospitals.

At the First Professional Examination in Anatomy and Physiology for the Diploma of Fellow held on May 5th, 6th, 10th, 11th, 12th, and 13th 135 candidates presented themselves, of whom 73 per cent. were referred and 27 per cent. were approved. The following is the list of successful candidates, amongst whom is one lady (Miss M. M. Basden):—

John Wroth Adams, St. Bartholomew's Hospital; James Noble Armstrong, Dublin University; Margaret Mary Basden, Royal Free Hospital; Charles Walter Gordon Bryan, L.R.C.P., M.R.C.S., St. Mary's Hospital; Edward Calvert, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Noel Godfrey Chavasse, B.A. Oxon., Oxford and Liverpool Universities; Frederick John Cleminson, M.A., B.C. Cantab., L.R.C.P., M.R.C.S., Cambridge University and University College Hospital; John Colgan, Trinity College, Dublin; Ernest Marshall Cowell, M.D., B.S. Lond., L.R.C.P., M.R.C.S., University College Hospital; Harry Cecil Rutherford Darling, M.B., B.S. Lond., L.R.C.P., M.R.C.S., University College; Edward David Davis, L.R.C.P., M.R.C.S., L.D.S. Eng., Charing Cross Hospital; Alfred Evan Lewis Devonald, Cork and St. George's Hospital; Frank Holt Diggle, M.B., Ch.B. Vict., L.R.C.P., M.R.C.S., Manchester University; George Edward Genge-Andrews, Guy's Hospital; John Torbet Smith Gibson, St. Mary's Hospital; Thomas Twistington Higgins, M.B., Ch.B. Vict., L.R.C.P., M.R.C.S., Manchester University; Alfred John Hull, L.R.C.P., M.R.C.S., Guy's Hospital; Charles Eric Sweeting Jackson, St. Mary's Hospital; John Cecil Jefferson, Manchester University; William Alexander Hogg McKerrow, M.B., Ch.B. Aberd., Aberdeen University; George Sefton Miller, Guy's Hospital; Andrew Samuel Moorhead, M.B Toronto, L.R.C.P., M.R.C.S., Toronto University and University College; John Morley, M.B., Ch.B. Manch., Manchester University; Albert Clifford Morson, L.R.C.P., M.R.C.S., Middlesex Hospital; Krishnan Gopinath Pandalai, M.B. Madras, Madras and Middlesex Hospital; Courtenay Henry Gerard Pochin, Guy's Hospital; Balcombe Quick, M.B., B.S. Melb., Melbourne University and Middlesex Hospital; John Frederick Gwyther Richards, Guy's Hospital; William Robinson, Guy's Hospital; Bidhan Chandra Roy, M.D. Calcutta, L.R.C.P., M.R.C.S., Calcutta University and St. Bartholomew's Hospital; Douglas Wilberforce Smith, M.B., B.S. Lond., L.R.C.P., M.R.C.S., Edinburgh University, Guy's and Middlesex Hospitals; Reginald Westmore Spence, King's College; Francis Theodore Talbot, M.B., B.C. Cantab., L.R.C.P., M.R.C.S., Cambridge and Leeds Universities; Ronald Ogier Ward, B.A. Oxon., Oxford University and St. Bartholomew's Hospital; Hugh Cameron Wilson, M.D., Ch.B. Edin., Edinburgh University and King's College; and Duncan Wood, L.R.C.P., M.R.C.S., London Hospital.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the recent examinations in Glasgow for the Diploma of Public Health the following candidates passed the necessary examinations:—

Malcolm Campbell, Thomas Campbell, Captain John Davies, William Arnott Dickson, Alexander Stewart Gordon, William Grier, Samuel Alexander M'Clintock, Frank Bedingfeld Macdonald, Walter James M'Feat, John Macintyre, Louis William Crombie Macpherson, George Glendinning Middleton, Peterswald Pattison, Oswell Everard Powell, John Reid, Henry Drummond Robb, John Scott, Hugh Rodger Sloan, and Arthur Samuel Walker.

The following candidates passed the first part of the examination:—

Ernest Hamilton Cramb, Jane Reid Foulds Gilmour, Mary Philip Graham, John Muir Kelly, David James M'Leish, Robert Alexander Mackenzie Macleod, Malcolm Bernard Gathorne Sinnette, Robert Tannahill Young, William Young, and William Alexander Young.

The following candidate passed the second part of the examination:—

Bhola Nath.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF IRELAND.—At the Conjoint Examinations held in April for the Final Professional Examination, the following candidates passed:—

A. M. J. Blake, H. F. Blood, V. J. P. Clifford, P. A. Doyle, E. P. Harding, J. T. Heffernan, A. K. Hogan, H. Hunt, C. Kelsall, D. J. Lyne, J. T. McKee, J. J. O'Connor, L. C. Rorke, H. B. Sherlock, and A. H. T. Warnock.

At the Conjoint Examinations held in May for the Diploma in Public Health the following candidates passed:—

Walter Biggar Bannerman, Elizabeth Hamilton Brook, Evelyn Elizabeth Dickinson, Robert Thomas Edwards, Charles Conway Fitzgerald, William James Deacon Inness, Hubert Peché Lobb, James King Patrick, Henry Joseph Raverty, and William de Wever Wishart.

ALCOHOL IN CHEMISTS' SHOPS IN THE UNITED STATES.—At a meeting of the American Pharmaceutical Association recently held in Richmond, Va., a most important and drastic decision was come to by the association advocating the abolition of alcohol as an article of sale in American druggists' shops. The association further earnestly urged the elimination of all traffic in "habit-forming drugs" as harmful to public morals and detrimental to the best interests of the American people.

SMALL-POX IN THE TOWN OF COBALT.—Small-pox has broken out in Cobalt, the silver-mining town in Northern Ontario. On May 4th there were 17 patients in the isolation hospital, four in one of the mines, and two segregated in houses in the town. All but two of the cases which have occurred so far have been of a mild type. 1500 people have already been vaccinated in Cobalt, and the mines have instituted a system of tickets whereby, if an employee is not vaccinated within a certain number of days, he is discharged.

BY an obvious slip in our brief obituary notice of His Majesty King Edward VII. we alluded to his dangerous attack of typhoid fever as having occurred in 1872. The Thanksgiving Service for his recovery took place in that year, his illness having been in the autumn of the previous year. It has been pointed out also that we have made no reference to the fact that his late Majesty was President of St. Bartholomew's Hospital for a long period of years, but we could not attempt to mention by name the numerous hospitals, institutions, and charities to which he gave not only his name but his active support.

SWANSEA HOSPITAL.—The Swansea Hospital was established early in the last century, and the present buildings are between 40 and 50 years old. Additions and alterations have been made from time to time, but it has now been decided that considerable enlargement is necessary. By building additional storeys it will be possible to add five new wards with a total accommodation for 82 patients. The roofs of the new buildings are to be flat and thus available for recreation or for open-air treatment. New kitchens, servants' bedrooms, dispensary, drug store, and waiting-rooms, together with accommodation for manufacturing aerated waters, are all included in the scheme of alterations which has been adopted by the board of management.

ROYAL COLLEGE OF SURGEONS IN IRELAND: GENERAL MEETING AND ELECTION OF OFFICERS.—A meeting of the College will be held on Saturday, June 4th, at 1 o'clock, to receive the annual report of the Council. Notices of motion received by the Registrar on or before Tuesday, May 24th, will have priority of consideration over any others which may be submitted. A meeting of the College will also be held on Monday, June 6th, at 1 o'clock, pursuant to the provisions of the Charters, to elect a President, Vice-President, Council, and secretary of the College

for the ensuing year. Fellows who may desire to have their names printed on the list of candidates for office will please signify their wish by letter to the Registrar, at the College, on or before Tuesday, May 24th, as it is necessary to include the names in the voting papers which are forwarded to the Fellows, and no candidate is eligible unless his application is received within the date specified.

THE PELLAGRA FIELD COMMISSION. — The following telegram was received from Dr. Sambon, who is at present in Italy in charge of the Pellagra Field Commission. It was dated May 13th and reached us too late for insertion last week:—"The Commission has definitely proved that maize is not the cause of pellagra. The parasitic conveyer is *Simulium reptans*." The Pellagra Investigation Committee in London has no further information as to the nature of the proof on which Dr. Sambon bases his conclusions. Captain Siler of the United States Army, who accompanied Dr. Sambon to Italy, has returned to London, and at a meeting of the Committee held on May 11th he reported that Dr. Sambon was carrying on his investigations chiefly upon epidemiological lines on methods which involved a considerable expenditure. It may be well, therefore, to remind our readers that money is required for further work. Several foreign Governments have invited the Committee to allow Dr. Sambon to prosecute the study of pellagra within their jurisdiction.

THE SANITARY CONDITION OF MONMOUTHSHIRE COLLIERIES.—A few months ago Mr. J. W. Davies, medical officer of health of the Ebbw Vale urban district, drew attention to the insanitary condition of the underground workings of some of the Monmouthshire collieries, and in a report which he subsequently sent to the Local Government Board he particularised several fatal cases of some form or other of blood poisoning contracted, in his opinion, in the collieries. It appears that Mr. Davies has been persistently refused permission to inspect the colliery workings in order that he might investigate for himself the existing conditions. The Home Secretary has now appointed a committee to report upon the matter. The members of the committee include Mr. J. S. Martin, I.S.O., and Mr. C. L. Robinson, two of His Majesty's inspectors of mines, together with Dr. D. Rocyn-Jones, medical officer of health of the Monmouthshire county council, Dr. N. N. Wade of Risca, and Mr. Storrer, veterinary surgeon of Abergavenny.

BOOKS, ETC., RECEIVED.

ARNOLD, EDWARD, London.

With a Prehistoric People. The Akikúyu of British East Africa. By W. Scoresby Routledge, M.A. Oxon., and Katherine Routledge (born Pease), Som. Coll. Oxon., M.A. Trin. Coll., Dublin. Price 21*s.* net.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BANKART, A. S. BLUNDELL, M.C. Cantab., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Belgrave Hospital for Children.

BARLING, SEYMOUR, M.B., M.S. Lond., F.R.C.S. Eng., has been appointed Assistant Surgeon to the General Hospital, Birmingham.

DAVIES, D. LEIGHTON, M.D., M.S. Lond., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Honorary Assistant Ophthalmic Surgeon to the Cardiff Infirmary.

THOMPSON, J. E., M.B., Ch.B. Aberd., has been appointed Resident Medical Officer at the Ashton-under-Lyne Workhouse.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ALBERT DOCK HOSPITAL, Connaught-road, E.—Senior House Surgeon. Salary £75 per annum, with board, residence, and washing. Also House Surgeon. Salary £50 per annum, with board, residence, and washing.

BENENDEN SANATORIUM.—Assistant Medical Officer, unmarried. Salary £80 per annum, with board, lodging, and laundry.

BIRMINGHAM AND MIDLAND HOSPITAL FOR SKIN AND URINARY DISEASES, Birmingham.—Clinical Assistant for three months. Salary at rate of 52 guineas per annum.

BRECKNOCK COUNTY AND BOROUGH INFIRMARY.—Resident House Surgeon, unmarried. Salary £120 per annum, with apartments, board, attendance, &c.

BRISTOL ROYAL INFIRMARY.—Honorary Medical Registrar.

BURY INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, residence, and laundry.

BUXTON, WYE HOUSE ASYLUM.—Assistant Medical Officer. Salary £120 per annum.

CANTERBURY, KENT AND CANTERBURY HOSPITAL.—House Surgeon, unmarried. Salary £80 a year, with board, lodging, and washing. Also Honorary Surgeon.

CHELMSFORD, ESSEX EDUCATION COMMITTEE.—School Medical Officer. Salary £350 per annum.

CHILDREN'S REST CONVALESCENT NURSING HOME, Roehampton, S.W.—Honorary Physician.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Honorary Aural Surgeon.

DUNDEE SCHOOL BOARD.—Chief Medical Officer. Salary £[illegible]00 per annum.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—Assistant House Surgeon. Salary £50 per annum, with board, residence, and laundry.

HEMEL HEMPSTEAD, WEST HERTS HOSPITAL. — House Surgeon. Salary £100 per annum, with rooms, board, and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—Assistant Casualty Medical Officer, unmarried, for six months. Salary £30, with board, residence, and washing. Also House Surgeon and House Physician, early in July.

HUNTINGDON COUNTY HOSPITAL.—House Surgeon. Salary £80 per annum and all found.

INDIAN MEDICAL SERVICE, India Office, London.—15 Commissioners in His Majesty's Indian Medical Service.

JERSEY GENERAL DISPENSARY AND INFIRMARY.—Resident Medical Officer. Salary £100, with board and lodging.

KENDAL, WESTMORLAND CONSUMPTION SANATORIUM.—Assistant Resident Physician, unmarried. Salary £100 per annum, with residence, board, &c.

LEEDS CITY INFECTIOUS DISEASES HOSPITALS AND SANATORIUM.—Two Resident Medical Officers, unmarried, for six months. Salary at rate of £110 per annum, with board, lodging, and washing.

LIVERPOOL DISPENSARIES.—Assistant Surgeon, unmarried. Salary £100 per annum, with board and apartments.

LONDON COUNTY COUNCIL.—Woman Inspector under Midwives Act, 1902, unmarried or widow. Salary £250 per annum. Also Assistant School Doctors in Public Health Department. Salary £120 per annum.

LONDON THROAT HOSPITAL, 204, Great Portland-street, W.—House Surgeon for six months. Salary £50 per annum.

MANCHESTER WORKHOUSE, Crumpsall.—Junior Resident Assistant Medical Officer, unmarried. Salary £110 per annum, with apartments, washing, &c.

MIDDLESBROUGH, NORTH RIDING INFIRMARY.—Assistant House Surgeon. Salary £75 per annum, with board, residence, and washing.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood, Middlesex.—House Physician at Northwood. Salary £75 per annum, with board, residence, and washing. Also Clinical Assistants for six months.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Albany Memorial), Queen-square, Bloomsbury.—Senior House Physician. Salary £50 per annum, with board and residence.

NOTTINGHAM GENERAL HOSPITAL.—Assistant House Surgeon. Salary £60 per annum, with board, lodging, and washing.

PRESTWICH, COUNTY ASYLUM, Manchester.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, with board, apartments, and washing. Also Locum Tenens, unmarried, for six to eight weeks. Salary 4 guineas per week, with apartments, board, &c.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—Two House Surgeons and House Physician, each for six months. Salary £60 per annum, with board, residence, and washing.

REDHILL, EARLSWOOD ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £130 per annum, with board, lodging, and washing.

RENFREW, COUNTY COMMITTEE ON SECONDARY EDUCATION.—School Medical Inspectors for No. 1 and No. 2 Districts. Salaries £300 per annum.

ROYAL EAR HOSPITAL, Soho.—Honorary Assistant Anæsthetist.

ROYAL EYE HOSPITAL, Southwark, S.E.—Honorary Assistant Surgeon.

RYDE, ROYAL ISLE OF WIGHT COUNTY HOSPITAL.—Resident House Surgeon. Salary £125 per annum.

ST. MARK'S HOSPITAL FOR CANCER, FISTULA, AND OTHER DISEASES OF THE RECTUM, City-road, E.C.—House Surgeon. Salary £80 per annum, with board, lodging, and washing.

SALFORD UNION INFIRMARY.—Resident Assistant Medical Officer. Salary £120 per annum, with furnished apartments, attendance, and rations.

SCARBOROUGH HOSPITAL AND DISPENSARY.—Junior House Surgeon for six months. Salary £80 per annum, with board, residence, and laundry.

SHEFFIELD ROYAL HOSPITAL.—Assistant House Physician, unmarried. Salary £50 per annum, with board, lodging, and washing.

STAFFORD, STAFFORDSHIRE GENERAL INFIRMARY.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.

STOCKPORT INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, washing, and residence.

TAUNTON, TAUNTON AND SOMERSET HOSPITAL.—Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.

UNIVERSITY COLLEGE HOSPITAL, Gower-street, W.C.—Assistant Physician.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—House Surgeon for six months. Salary £30, with board, lodging, and laundry.

WAKEFIELD, COUNTY COUNCIL OF THE WEST RIDING OF YORKSHIRE.—Lady Medical Inspector. Salary £300 per annum.

Notes, Short Comments, and Answers to Correspondents.

HEALTH AND CLIMATE OF PERU.

Mr. Lucien J. Jerome, British Consul-General, in his annual report just issued through the Foreign Office, observes that on the whole Peru may be said to be a healthy country, notwithstanding the fact that bubonic plague has got a firm hold on the coast towns and even in Lima itself, where, as in the neighbouring port of Callao, it is sporadic and cases are constantly occurring. Greater precautions are now taken to prevent the reintroduction of yellow fever into Peru, and the country has been quite free of this disease of recent years. From statistics covering a period of 18 years the death-rate of the town of Lima is estimated at 27·59 per 1000. In some of the parishes inhabited by Indians (natives) and by Chinese it is, however, as high as 37·40 per 1000. In fact, the highest death-rate is among the native races and the lowest among Europeans and persons descended from pure European stock. The diseases which cause the greatest mortality in Lima and Callao are tuberculosis, infantile diseases, typhoid fever, influenza, and disorders of the intestines. As regards tuberculosis, the following comparative figures for Spanish-American towns, showing the mortality per 10,000 inhabitants, are very interesting: Lima, 62·1; Caracas, 60; Rio de Janeiro, 38; Santiago, Chile, 38; Havana, 32·7; Monte Video, 16; Buenos Ayres, 14·2; Mexico City, 14; San Salvador, 13·7. Europeans suffer very much in Lima from malaria and from the very enervating climate, which saps all vitality and makes anyone in the least inclined to be influenced by these conditions extremely, if not dangerously, ill. The following figures show the development of bubonic plague from its appearance in Peru in 1903:—Number of cases in 1903 (October, November, and December), 9; in 1904, 377; in 1905, 145; in 1906, 110; in 1907, 171; in 1908, 249. In 1908, out of a total number of 249 cases 117 proved fatal, showing a death-rate from this disease of 47 per cent. In each year a great increase in the number of cases has been noted in the month of April.

The climate of Peru, Mr. Jerome remarks, is a surprise, and it is an unexpected relief to the traveller coming south from Panama and Guayaquil, where the heat is excessive, to meet, shortly after leaving the latter place, with the cool south-west breezes. The mean annual temperature of the coast provinces is 68° F.; in the hotter months—January and February—the mean temperature is between 82° and 86°. The dry heat is not oppressive, and after 11 A.M., when the torrid sun has rarefied the atmosphere over the desert, sea air comes rushing to this area of low pressure, all life is refreshed by the breeze, and often a little rain is scattered over the maritime range. In the evening, when the surface of the desert grows cool, the wind sets out to sea again, bringing cool breezes from the mountains. Inland, as in the case of the valley of the Rimac, the climate is much more normal for the latitude than that of the coast, and while at Callao near the mouth of the river one finds a climate resembling that of Southern Europe, at Chosica, some 30 miles to the east, one begins to get a climate not unlike that of Cuba or the coast provinces of Mexico.

GUINEA-WORM IN UNUSUAL POSITION.

To the Editor of THE LANCET.

SIR,—I think the following case may be of some interest on account of the position.

A Lascar on board had a Filaria medinensis, or Guinea-worm, the position being one inch above the coccyx, and half an inch to the right of the spine; it was 2 feet 3 inches long.

I am, Sir, yours faithfully,

P. C. P. TAYLOR.

H.M. Transport *Rewa*, Southampton, May 13th, 1910.

HABIT-FORMING DRUGS.

THE misuse of habit-forming drugs has been regarded for some time as one of the great national evils in the United States. The Department of Agriculture has taken up the subject, collecting statistics and analysing so-called "cures," and from time to time has published the results in order to inform the public of the menace to the public welfare in the indiscriminate sale of habit-forming drugs. The latest bulletin, by Dr. L. F. Kebler ("Habit Forming Agents," Farmers' Bulletin, No. 393, United States Department of Agriculture, Washington, 1910, pp. 19) shows that the amount of opium consumed in the United States per capita has been doubled within the last 40 years, although no increase has been observed during the past decade. It is estimated that about 150,000 ounces of cocaine are consumed annually in the United States, in addition to large quantities of acetanilid, phenacetin, antipyrine, caffeine, chloral hydrate, codeine, dionine, and heroin, in spite of anti-narcotic legislation, publicity, and other deterrent factors. In controlling the evil, one great step in advance was made by enacting laws requiring a declaration on the label of the quantity of certain habit-forming drugs contained in remedies intended for human or

veterinary use. But the consumer is usually ignorant of the harmful nature of these drugs and the Department of Agriculture is endeavouring to meet the difficulty by public lectures and by publishing warning bulletins which are being freely distributed throughout the country. The various classes of remedies are considered in the bulletin, starting with "soothing syrups" for children. In a representative selection of 13 preparations, nine contained morphine, while codeine was found in one, heroin in one, chloral hydrate in one, opium in one, and cannabis indica in one. Soothing syrups containing these habit-forming drugs, when used without discrimination, are held by Dr. Kebler to induce tendencies which under unfortunate conditions later in life may be aroused to activity and develop an evil habit of one form or another. The number of remedies concocted for the treatment of diseases of the nose and lungs is legion, their vaunted values depending, as a rule, upon the presence of cocaine, chloral hydrate, codeine, heroin, morphine, opium, and tobacco. The absence of a recognised treatment for eradicating asthma has led to the marketing of numerous so-called "cures," for which the public pay excessive prices. There are a goodly number exploited at present which have as their basic agents cocaine, morphine, opium, or chloral hydrate. An example of the cocaine type consists of a bottle of medicine containing cocaine to be used as a spray with an atomiser. The price of the latter is $12.50. It is true that the amount of cocaine introduced into the nose by means of a spray is small, but it is well known that exceedingly small amounts are required, when used in this manner, to produce constitutional effects. In fact, this is the popular manner in which cocaine is taken by those addicted to its use. They are commonly known as "sniffers" or "coke sniffers," because of the fact that cocaine is sniffed into the nose. A very great number of advertised "catarrh cures" contain cocaine, and lead to the contraction of the habit. The danger of such preparations in the hands of the public is shown by the fact that the medicines are supplied so long as the patient is able and willing to pay for them. It is significant that the demand for these preparations is greatest in those States where the most stringent anti-narcotic laws are in force.

A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—With reference to a short paragraph which appeared in some of the Liverpool newspapers this week, alluding to an address which I delivered in London last Monday on the subject of Demoniacal Possession, I should like it to be known that the paragraphs in question were sent to these papers without my consent or approval; that the wording of some of them was not strictly correct; and that I am very sorry such notices appeared.—I am, Sir, yours faithfully,

Liverpool, May 14th, 1910. C. WILLIAMS.

Dentocaine.—We do not quite understand our correspondent's questions. If he had written out a concrete case and entrusted us with the names the situation would have been much plainer. Every man on the Medical Register is qualified to practise dental surgery, but in our opinion the words "Dental Surgeon" on a door-plate might imply the possession of some special dental qualification. We do not think that a man should so describe himself on the door-plate that the public might regard him at the same time as a general practitioner and as a dental specialist, when he has no diploma proving a special dental training.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

MONDAY.

SPECIAL MEETING OF FELLOWS OF THE SOCIETY at Morley Hall, George-street, Hanover-square, W.: at 5 P.M.

Discussion:

On Vaccine Therapy, its Administration, Value, and Limitations (opened by Sir Almroth Wright, F.R.S.).

At this, the first meeting, the following gentlemen will continue the Discussion:—Dr. C. Slater, Dr. L. Colebrook, Dr. StClair Thomson, and Dr. W. d'Este Emery.

ODONTOLOGICAL SECTION (Hon. Secretaries—D. P. Gabell, E. B. Dowsett, J. Howard Mummery) at 15, Cavendish-square, W.: at 8 P.M.

Paper:

Mr. Douglas E. Caush: The Spindles of Von Ebner (illustrated by lantern slides).

Casual Communications:

Mr. Arthur S. Underwood: Some Egyptian Skulls.

Mr. G. Thomson: A Case showing the Result of Extraction of the Six-year-old Molars.

TUESDAY.

MEDICAL SECTION (Hon. Secretaries—A. M. Gossage, A. F. Voelcker): at 5.30 P.M.

Annual Meeting for Election of Officers and Council, followed by Ordinary Meeting.

WEDNESDAY.

SPECIAL MEETING OF FELLOWS OF THE SOCIETY at Morley Hall, George-street, Hanover-square, W.: at 5 P.M.

Discussion:

On Vaccine Therapy, its Administration, Value, and Limitations (re-opened by Dr. Hale White, and continued by the following gentlemen):

Dr. J. W. H. Eyre, Sir W. Watson Cheyne, Bt., C.B., F.R.S., Dr. John Matthews, Dr. Harold A. Des Vœux, Dr. H. W. Bayly, Dr. A. Butler Harris.

THURSDAY.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION (Hon. Secretaries—W. J. Gow, G. F. Blacker): at 7.45 P.M.

Annual General Meeting.—Election of Officers and Council.

Papers:

Dr. F. J. McCann: Cæsarean Section in the Treatment of Eclampsia Gravidarum.

Dr. A. J. Wallace: Contribution to the Life-history of Fibromyomata of the Uterus.

FRIDAY.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—E. I. Spriggs, J. P. Lockhart Mummery, J. T. Leon) at 11, Chandos-street, W.: at 4.30 P.M.

Cases:

Dr. H. Bellingham Smith: Amaurotic Family Idiocy.
And other cases.

SECTION OF ANÆSTHETICS (Hon. Secretaries—Llewelyn Powell, R. W. Collum): at 6 P.M.

Annual General Meeting: Election of Officers and Council for Session 1910–11.

EPIDEMIOLOGICAL SECTION (Hon. Secretaries—W. H. Hamer, G. S. Buchanan): at 8.30 P.M.

Paper and Discussion.

SATURDAY.

BALNEOLOGICAL AND CLIMATOLOGICAL SECTION (Hon. Secretaries—Septimus Sunderland, F. A. de T. Mouillot).
Provincial Meeting at Buxton.

Annual General Meeting. Election of Officers and Council for Session 1910–11.

Visits to Devonshire Hospital, Town Baths, Examination of Cases, Receptions, &c.

Reserved carriage leaves St. Pancras at 10.5 A.M., returning on Monday, May 30th, at 9.50 A.M.

Programme will be sent on application to Dr. Sunderland.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8 P.M., Annual Oration and Conversazione. Orator—Mr. W. H. Battle.

MEDICO-LEGAL SOCIETY, 11, Chandos-street, Cavendish-square, W.C.

TUESDAY.—8.15 P.M., Dr. Major Greenwood: The Policy of the English Poor-Law and its Proposed Medical Reform.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

FRIDAY.—8.30 P.M., Dr. R. Howard (Zanzibar): Functional Neuroses in Dark Races.—Dr. H. S. Houghton (Wuhu): Notes on Infection by Schistosomum Japonicum (from the Laboratory of the Wuhu Hospital).—Dr. W. Nicoll: The Bionomics of Helminths.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. T. C. Fox: Clinique (Skin). 5.15 P.M., Lecture:—Mr. H. J. Paterson: The Simulation of Gastric Disease by Chronic Appendicitis.

TUESDAY.—4 P.M., Dr. H. Mackenzie: Clinique (Medical). 5.15 P.M. Lecture—Mr. A. H. Tubby: Treatment of Lateral Curvature of the Spine in Children.

WEDNESDAY.—4 P.M., Mr. E. L. Evans: Clinique (Surgical). 5.15 P.M. Lecture:—Dr. J. Collier: Myelitis.

THURSDAY.—4 P.M., Dr. C. O. Hawthorne: Clinique (Medical). 5.15 P.M., Lecture:—Dr. G. Pernet: Lupus Erythematosus.

FRIDAY.—4 P.M., Dr. D. Grant: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Armour: Operations for Appendicitis.

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 11.30 A.M., Demonstrations in Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Low: Insects as Carriers of Disease in Tropical Medicine.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Dr. Bernstein: What can be Learnt from a Blood Examination.

THURSDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery. (Lecture I.)

FRIDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. Medical Registrar: Demonstration of Cases. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Pritchard: Clinical Pathology.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 3.15 P.M., Special Lecture: Mr. R. Carling: Cancer of the Intestines.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 2.15 P.M., Special Lecture:—Dr. R. Bradford: Chronic Peritonitis.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4 P.M., Lecture:—Dr. Acland: Inflammatory Lesions in the Neighbourhood of the Diaphragm.

THURSDAY.—Dr. Wethered: Demonstration at Frimley Sanatorium.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY AND FRIDAY.—3.45 P.M., Lecture:—Mr. C. Nourse: External and Middle Ear.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture.—Dr. D. Ferrier.

FRIDAY.—3.30 P.M., Clinical Lecture:—Mr. L. Paton: Optic Neuritis.

HOSPITAL FOR SICK CHILDREN (UNIVERSITY OF LONDON), Great Ormond-street, W.C.

THURSDAY.—4 P.M., Demonstration:—Mr. Kellock: Selected Surgical Cases in the Ward.

ROYAL EYE HOSPITAL, St. George's Circus, Southwark.

THURSDAY.—6 P.M., Lecture: Mr. G. T. B. James: Binocular Vision in its Relation to Some of the Refractive and Muscular Anomalies of the Eye. (Any practitioners and students interested in the subject are invited to attend.)

MANCHESTER ROYAL INFIRMARY.

TUESDAY (May 31st) AND FRIDAY (June 3rd).—4.30–5.30 P.M., Honorary Staff: Post-Graduate Clinical Demonstration (Medical, Surgical, and Special Departments).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 35, Rue Franklin, Asnières, Paris.

Three Clinical Lectures

Delivered at the Middlesex Hospital

BY SIR HENRY MORRIS, M.A., M.B. LOND., F.R.C.S. ENG.,

EMERITUS LECTURER ON SURGERY IN THE MEDICAL SCHOOL.

LECTURE I.

Delivered on Feb. 22nd.

LYMPHATIC ŒDEMA OF THE LEG AND FOOT WITH CYANOSIS AND DROP-FOOT.

GENTLEMEN,—When face to face with a person afflicted with a disease, or the result of an injury, the first questions which you will, or at any rate which you ought to ask yourselves are, "What is the nature of the affection?" and "What is the cause of it?" Before thinking about the treatment you will adopt, or whether or not you can do the patient any good, you must do your best to find answers to these queries.

The case which I wish to speak about this afternoon was sent to me with a precise, and in my opinion a perfectly correct diagnosis, ready made. I was prepared to see a young woman with "foot-drop and an uncertain œdema of the foot and leg which presented the aspects of a chronic proliferative lymphangitis following a scald inflicted some time previously." After examining the patient I had no hesitation in confirming the diagnosis. A mere glance sufficed to convince one of the drop-foot and the œdematous character of the swelling. But what about the *nature* of the œdema? and what about the pathological condition which occasioned it?

I. *As to the nature of the œdema.* What proof was there of its being lymphatic and not venous? Briefly, it was not venous œdema (1) because it was so persistent and neither disappeared nor appreciably diminished by compression or posture; (2) because the skin itself was somewhat implicated and the swollen tissues were much firmer and more brawny than they are when the œdema is venous; (3) because of the very abrupt termination or limit of the puffiness; and (4) because of the absence of phlebitis, of any manifestation of pressure upon or interference with the return of blood through the principal veins, or of any visceral disease.

CAUSES OF VENOUS ŒDEMA.

Now, concerning the fourth reason which I have just stated, let us consider for a moment what the causes of venous œdema of the legs are.

First, there is the impediment to the return of blood to the heart by cardiac or hepatic disease; there are the changes in the character of the blood and the deficient elimination of water in certain forms of renal disease; and then there is the passive exudation from the veins in persons debilitated by exhausting disease, by loss of blood, by long standing, and in old age. From any of these causes both legs are apt to become œdematous, whilst the visceral conditions referred to are prone to give rise to effusion into the great visceral cavities as well as into the general cellular tissue of the whole body.

Secondly, there are conditions which produce continuous pressure upon main veins, such, e.g., as the pregnant uterus, uterine, ovarian, and other pelvic and abdominal tumours, and inflammatory adhesions within the pelvis. From this set of causes the œdema may symmetrically affect both legs, though more frequently one only is swollen.

Thirdly, there is the œdema, often sudden and extensive, which ensues from plugging of a main vein from phlebitis.

It is important for you to remember, however, that phlebitis, especially of the smaller and medium-sized veins, may be absolutely unaccompanied by œdema; so that you must not assume from an absence of swelling that phlebitis is not present; or that pain in an entirely unswollen limb is not due to it. You need hardly be reminded, I am sure, that owing to free venous anastomoses and the consequent rapid and plenteous compensatory circulation, there may be great obstruction to venous circulation without any œdema of the corresponding limb. We see this absence of œdema in cases of great dilatation of varicose veins, and of obstruction from pressure caused by enlarged lymphatic glands or new growths.

PHLEGMASIA DOLENS.

Having given the reasons for considering an œdema to be lymphatic and not venous in origin, and having enumerated the various conditions which tend to bring about venous œdema, I will make one or two remarks respecting "*phlegmasia dolens.*" The phenomena of this disease are often attributed to venous obstruction due to phlebitis and phlebitic thrombosis of the deep veins; but against this explanation are (*a*) the firm, doughy character of the œdema, and (*b*) the absence of compensatory enlargement of the superficial veins. Without controverting the statement that plugging of the veins is a frequent condition in phlegmasia dolens, I would nevertheless assert that if lymphatic obstruction is not the sole or the essential factor of the disease, there is at any rate a combination of lymphatic with venous obstruction in its pathological causation.

RELATION OF THE LYMPHATIC AND VENOUS RADICLES TO LYMPH SPACES.

For the proper appreciation of morbid anatomy and morbid physiology a knowledge of normal anatomy and physiology is essential. I should like, therefore, to refer you, if you need your memories to be refreshed on these matters, to the Arris and Gale lectures on the "Physiological Factors involved in the Causation of Dropsy," delivered by Professor E. H. Starling at the Royal College of Surgeons of England (Professor Starling's classification of the physiological factors of dropsy and some of the details respecting them were quoted by the lecturer); and to the admirably illustrated section on "The Lymphatics" by Dr. Florence R. Sabin, in Morris's "Treatise on Anatomy."[1] Since Aselli Gasparo discovered the lacteals in 1622 (a discovery, by the way, which the immortal Harvey, the discoverer of the circulation of the blood, would never accept), and since Pecquet in 1647 discovered the receptaculum chyli, the anatomy of the lymphatic system has been diligently studied. But it was reserved for Dr. Sabin in 1902 to be the first to point out that the true origin of the lymphatic tubes is as outgrowths from the veins within the body of the embryo. Until recent years the prevailing theory was that the lymphatic system took its origin from dilated tissue spaces, that the lymphatic radicles terminated in these spaces, and that therefore these spaces had a relation to the lymphatic capillaries different in kind from that which they held to the veins. It has, however, of late been shown by Dr. Sabin and others "that the lymphatic ducts grow in length by a sprouting of the endothelium of the veins, similar to that which characterises the growth of the blood-vessels." The lymphatic system can be sharply distinguished from the tissue spaces, and the lymphatic vessels have a definite lining of endothelium arising from the endothelium of the veins.

The tissue spaces are the spaces between the individual cells of any organ, and in the meshes of the connective tissue fibres, and they are filled with a fluid derived from the plasma of the blood. The spaces are inaptly styled "*lymph spaces*" and the fluid in them is called "lymph," whereas it is really a fluid derived from the plasma of the blood. These spaces are anatomically "distinct from the lymphatics, and are no more a part of the lymphatic system than they are a part of the blood vascular system."

Whilst in a few special places there seems to be an open circulation from the tissue spaces into the lymphatics,—just as there is into the blood-vessels from the spaces in the spleen and bone marrow,—yet permanently open lymphatics in other parts of the body have not been demonstrated, and free absorption from the tissue spaces goes on through temporary apertures between the cells of the endothelium of the lymphatics.

The knowledge of these facts makes it easier to understand the interdependence and mutual relation of the venous and lymphatic factors of œdema and dropsy, and to follow the vicious circle in which an œdema starting in the lymphatic system induces venous œdema, and that again in turn aggravates the lymphatic factor. Furthermore, it has been shown that granules injected into an artery are returned by the lymphatics as well as by the veins, and also that when granules are injected into a muscle, where there are no lymphatic capillaries, these same particles

[1] Fourth edition, 1907.

pass into the lymphatics of the tendons. Hence we may infer that toxins and other poisons which injure the endothelium of the blood vascular system will by reaching the lymphatics injure the endothelium of that system also, and that thus the same cause which impairs the function of the blood vascular system may impair that of the lymphatic system too.

II. *As to the pathological state which induced the œdema.*—We shall be assisted in arriving at a knowledge of the pathogenesis of lymphatic œdema by passing in review the several causes of lymphatic obstruction and the part of the lymphatic system in which they severally occur.

CAUSES OF LYMPHATIC OBSTRUCTION.

First, stenosis of the orifice of the superior vena cava tends to cause lymphatic œdema by interfering with the due discharge of the contents of the thoracic ducts owing to backward pressure in the venous circulation. This is a rare occurrence, but a case was published some years ago in which stenosis of the cardiac orifices of both the great venous trunks, in a woman aged 43, was followed by general and excessive dropsy and œdema of a lymphatic as well as a venous character.

Secondly, obliteration, or dilatation from obstruction, of the thoracic duct may be caused by defective valves or by the pressure of tumours—cancerous, glandular, or aneurysmal.

Thirdly, obstruction in the lymphatic trunks may be caused by permeation from without by new growths; or occlusion may occur as the result of repeated attacks of lymphangitis of these trunk vessels. In cases of obstruction by permeation of new growth the œdema is solid and permanent; in inflammatory cases the swelling may subside with the inflammation of the lymphatics or with the establishment of collateral lymphatic circulation.

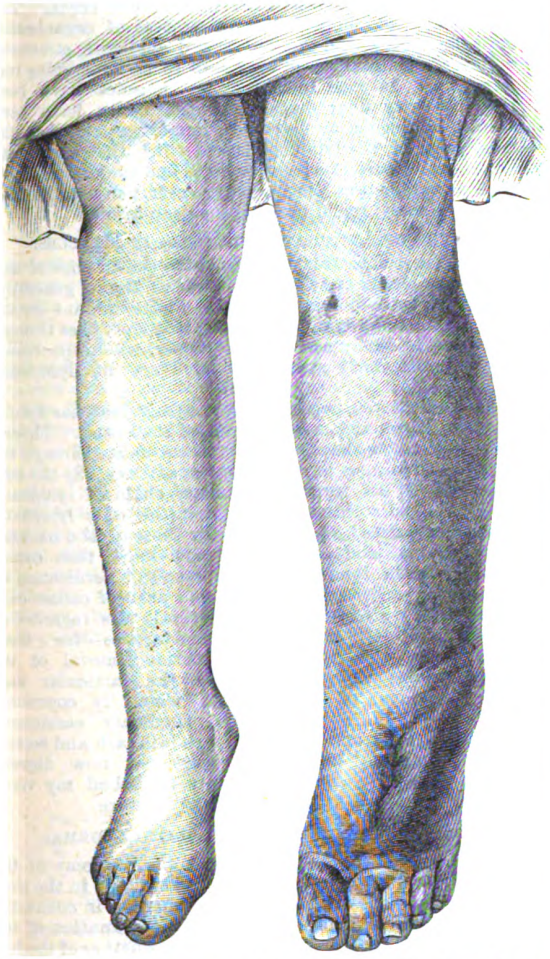
Fourthly, inflammation of the lymphatic capillaries and of the surrounding cellular tissues is by far the commonest cause. It may originate in a variety of ways. The inflammation may commence in the lymphatic capillaries and spread to the cellular tissue, or *vice-versâ*. This is the form of lymphangitis which has been called "*reticular*" to distinguish it from inflammation of the larger ducts.

SYMPTOMS OF RETICULAR LYMPHANGITIS.

When quite superficial it is seen in the various forms of erythema and dermatitis; when deeper seated it presents itself in the form of cellulitis. When acute the œdema is very transient, passing off with the inflammation; when the inflammation is chronic the œdema is prone to persist. Lymphatic œdema, even of the solid variety (which I will describe later on), used often to be met with after repeated attacks of erysipelas, but it is rarely seen now in that association because modern aseptic and antiseptic measures have so largely cut short or altogether prevented so-called idiopathic erysipelas as well as traumatic erysipelas and other infective surgical diseases.

In the case which I will now relate to you there was a complete absence of any sign of cardiac or thoracic duct obstruction; also of any carcinomatous, sarcomatous, or other infiltrating growth; and also of any obstruction, dilatation, noduliform sacculation, or hardening of the lymphatic trunks. It is usual in lymphangitis of the larger superficial lymphatic vessels to be able to see them as hard, knotty cords, or if the deeper lymphatics are inflamed to be able to feel them along the course of the arteries. Formerly it used to be commonly said that "lymphangitis is seen, phlebitis is felt," but this aphorism is bad. It must be put aside as misleading. It errs in two particulars, both as to what it states and what it implies, for an inflamed lymphatic if deep cannot be seen, and an inflamed vein if superficial—as, for example, the long saphena—may be seen as well as felt. If by being "felt" pain is meant, then again the aphorism is misleading, because lymphangitis is often very painful.

For the several reasons just stated the diagnosis formed in the following case was that the lymphatic œdema had been set up as a result of chronic reticular lymphangitis.



On Jan. 29th of this year a school teacher, aged 23 years, consulted me, on the advice of Mr. Thomas Carwardine of Bristol, about a swelling of the left foot and leg, which, in spite of a variety of treatment, including lymphangioplasty, was still progressing higher upwards towards the knee. She had scalded her foot on Oct. 23rd, 1908, by upsetting a kettle of boiling water over it. Boracic ointment was applied to the resulting sore and in six weeks it was healed. She then resumed her duties, her foot being quite free of pain, swelling, or stiffness. But after a fortnight the foot began to swell and to be painful, and a mottled, bluish, puffy swelling appeared in front of the ankle. The foot was very soon so swollen that she was unable to wear a shoe. After the Christmas holidays she returned to school work with the opening of the term, but was unable to continue beyond the fourth day. On Jan. 3rd, 1909, she was admitted into the Bristol General Hospital, and there remained 10 weeks; the treatment employed during this time consisted in the application of a back splint, bandaging, electricity, massage, and painting with iodine. The swelling disappeared, but returned immediately she began to get about, so that in less than three weeks she sought further advice at the Bristol Royal Infirmary, and there came under the care of Mr. Carwardine. On April 1st the foot-drop was corrected under gas; the tissues were very rigid, and adhesions about the ankle gave way audibly under the forcible movements. An anæsthetic was administered again a week later, but there were no adhesions to break down; the sacral region and the whole pelvis were carefully examined. After this, massage was employed and the patient was discharged on April 10th. She remained away till April 29th, when she was readmitted, as the ankle was more swollen and painful than before. The œdema was limited to the ankle and foot, and was most marked along the outer part of the dorsum pedis. Under $CHCl_3$ two definite adhesions were broken down. Massage was repeated. A week later there was observed an area of considerable puffiness just below, and in front of, the outer malleolus; it was very soft and painful, but around it the tissues were slightly more resistant than elsewhere. A small incision was made into the soft puffy swelling, but no pus, only dark fluid blood, escaped. After this the ankle became still more swollen and painful. The left calf had wasted one inch, but the muscles acted well to galvanism and faradism. On June 24th, when she left the infirmary, the ankle was still œdematous but not fluctuating, and the skin was more or less cyanosed. On Sept. 10th she was again readmitted in much the same state. The foot was very swollen and the œdema extended to two inches above the ankle, where it abruptly ceased. The skin over the swollen parts was of a bluish colour, but just above there was an area of hyperæmia. The X rays were employed to the foot and leg and a skiagram was also taken of the pelvis, but nothing abnormal was detected. On Sept. 14th lymphangioplasty was performed, four threads being passed from the dorsum of the foot to just below the knee. After the operation "the swelling rapidly subsided, and the skin regained a normal appearance. Some slight swelling, however, still remained on the outer side of the foot, with hyperæmia and tenderness. Movements at the ankle-joint were much freer than before the operation." It had previously been recorded in the notes that the œdema varied, and had subsided considerably on two or three occasions. Mr. Carwardine's own note is: "There was no permanent benefit from the operation. The œdema gradually spread up the leg, with a well-defined congested margin and a circular depression round the limb above the margin. The skin was dusky and congested from marked stasis whenever the foot was dependent."

After an absence for nine days the patient returned to the Royal Infirmary on Oct. 16th with the foot still more swollen and painful; and five days later an entry was made in the notes that the œdema then extended half-way up the leg and that "the tracks of two of the buried silk threads are marked by red lines in the skin."

The morbid condition had slowly ascended the leg up to the date of her visit to me (Jan. 29th, 1910). The accompanying woodcut gives an excellent idea of the appearance of the limb as I saw it. The toes, foot, and leg to within an inch and a half of the tibial tubercle were swollen. Just beyond, where the swelling terminated, there was a well-defined circular depression on the level of two small scars, the result of the lymphangioplasty, as I suppose. The skin was cyanosed, especially over the dorsum of the foot and along the outer side of the leg; there was pronounced drop-foot, and the ankle-joint was rigid and motionless. There were no enlarged glands to be felt, no evidence of any constitutional disease, and the sensation of the limb was good.

The remarks made by the patient herself and by her

mother were to the effect that the limb had been getting worse ever since the operation, and doubtless in a way this was true. But it is clear from the written record that there was immediate and considerable improvement after the lymphangioplasty, although, unfortunately, this improvement was only of very brief duration. Certainly no harm, as far as I could ascertain, had been done by the operation, and although almost the last note made when the patient was last in the Bristol Royal Infirmary tells of red lines in

the skin over the course of two of the silk threads, the threads apparently had not to be removed, nor is there any mention made of suppuration in their tracks having occurred.

TREATMENT OF LYMPHATIC ŒDEMA.

The question of treatment was clearly a most important one in this case. The youth of the patient, the fact that she would be dependent for her livelihood on her profession of a teacher, the utter uselessness of the limb as it was, the pain it caused her, and, almost worst of all, the fact that the disease was slowly creeping up the limb, all had to be taken into serious account.

Ought the limb to be amputated at once? If not, was it not probable that amputation at a higher level would have to be resorted to later on? Should a trial be made of the somewhat empirical treatment by ligation of the main artery, as suggested several years ago by Carnochan and successfully employed by himself, Vanzetti, and others? Was it possible that the cause of the disease was due to an invasion of the tissues by some bacterial infection, and, if so, might not an injection of a vaccine made from a pure culture of the micro-organism, or of the organism itself bring about a cure? Or, lastly, should a trial be made of inunctions, the internal administration of drugs, and a more prolonged use of bandages, massage, and posture?

Certainly the ligation of the femoral artery was worth trying before considering the question of amputation. It is impossible to deny that ligature of the main artery of a limb has occasionally proved successful; indeed, quite an encouraging proportion of cases in which it has been employed have been cured. Tying a main artery does not reduce the size of a normal limb, but it does of an elephantiasic one. Its mode of action has been explained by the increased activity of the process of absorption which is said to follow when the force of the vascular circulation is weakened.

But bearing in mind that lymphatic œdema from an inflammatory cause is not fatal, that many persons have lived from 25 to 55 years with this condition, that a cure may reasonably be expected in cases of recent origin, and sometimes occurs in advanced and old-standing cases, I was averse to the adoption of any drastic treatment. Before resorting to ligature of the femoral or to amputation, and in the event of the fluid in the affected tissues being proved to be sterile, I was in favour of continuing palliative remedies. I therefore suggested that the patient should take small doses of potassium iodide, that the leg should be kept elevated and bandaged, and that inunctions of mild mercurial ointment, or of equal parts of this and of an ointment of iodide of lead, should be diligently tried.

In acknowledging my letter Mr. Carwardine wrote on Jan. 31st: "A bacteriological examination was made at an early stage"; and in a subsequent communication he informed me that Professor Walker Hall had been consulted from the pathological and bacteriological point of view; also that "some of the serous fluid was withdrawn with a syringe and examined for organisms, but so far as I remember none were found." Nocturnal blood had also been examined with negative result. Again, on Feb. 11th, Mr. Carwardine wrote: "I saw the patient yesterday: the leg is much bigger than ever before; and your suggestions are being carried out for the present to see the effect." The next and last communication I received from him was on March 8th last, five weeks and three days after the patient's visit to me, and just a fortnight after the delivery of this lecture. It tells as follows: "The sequel is that the œdema of the leg has gone down; but that the patient has hæmoptysis with distinct physical signs of tuberculosis at the right apex."

CAUSES OF RETICULAR LYMPHANGITIS WITH ŒDEMA.

The history of this case leaves little, if any, doubt that the scald of the foot was the cause of superficial lymphangitis, and this in turn of the lymphatic œdema. I have known a similar condition to have occurred in the forearms of a girl after a scald. Anything, such as a chill, a scratch, abrasion, twist, sprain, or friction, posture, or the pressure of a tight sleeve or bandage, may set up a simple reticular lymphangitis, either attended or not with erythematous redness of the skin. If the inflammation of the lymphatics is continued or repeated it will be followed by lymphatic œdema of the affected part. The cases of lymphatic œdema which we meet with in this country have usually their origin in some simple general cause of this kind. I have lately been consulted by a gentleman (recently home from India) on account of recurrent lymphatic œdema of the forearm and back of the hand. Fourteen years ago I removed a large lipoma from his left pectoral region. Immediately after recovering from the operation he went out to India to take up a high official position there. During the last 15 months of his residence in that country his left forearm and hand swelled and were painful, occasionally, after prolonged exertion on shooting expeditions. The puffiness after continuing a week or less disappeared. In January last, after a few days' shooting, the œdema came on and did not pass off again as on previous occasions. The forearm and arm below the deltoid insertion were slightly swollen, the back of the hand was distinctly puffy and somewhat painful, and there was considerable stiffening of the fingers. Not unnaturally, perhaps, he was concerned to know if there was any connexion between the supple moveable scar in the pectoral region and these attacks of localised œdema of the upper limb. I was, of course, able to assure him that there was not. Nor could I find any assignable cause for the symptoms other than the effort, frequent recurrence of the same posture, and possibly some slight friction of the forearm attending the exercise of shooting.

In rare cases lymphatic œdema has been set up by the inflammation around a chronic ulcer or by the extension of inflammation to the superficial lymphatics from some deep-seated disease, such as caries or necrosis of a bone, or inflammatory disorganisation of a joint, especially the knee-joint. Lymphatic œdema has also been observed in association with syphilis, tubercle, and cancer. The last-mentioned disease in its advanced stages as a cause of solid œdema of the upper limb is unhappily only too well known in this hospital; but we may look forward with hope that the dire and terrible sufferings which this condition causes, and for which in some of the worst cases amputation of the whole upper quarter has been practised in this hospital and elsewhere, will in future be ameliorated by the more clement operation of lymphangioplasty, which is one of the more practical results of the research work which has been so well carried on in our hospital.

Lymphatic œdema is sometimes very localised. It may begin in any part of a limb and may spread upwards from the fingers or toes, or downwards from any point, or it may extend both upwards and downwards at the same time when it commences at some situations such as in the integuments near the patella.

Lymphatic œdema is sometimes seen as a *congenital* affection of a cheek, a limb, or a section of the abdomen in new-born infants; in these cases there is an indurated œdematous swelling identical with that which is produced by lymphangitis in older persons. The dorsum and the sole of the foot are the parts in new-born infants which are most prone to the affection; and this is noteworthy because in the sole of the foot the subcutaneous capillary plexus of lymphatics is more abundant than in any other area of the lower limb.

Both sexes and all ages are liable to reticular lymphangitis and lymphatic œdema, but it occurs most frequently in young adult males.

ELEPHANTIASIS.

In advanced cases in which the œdema has been of long standing, hypertrophy and induration of the connective tissue are superadded to the œdema. This hypertrophy is not necessarily, nor always, of an inflammatory origin, but is a result of mere chronic persistent œdema. It is due to the organisation of the exuded plasma cells and to the rapid multiplication and growth of the cells of the connected tissue of the part into which the passive outflow of the lymph plasma has occurred.

To this condition of œdema with hypertrophy, different names have been applied, such as solid œdema, elephantiasis Arabum, scleriasis, bucnemia tropica, and several others besides. It is common in hot, moist climates, and is endemic in Barbadoes (hence called Barbadoes leg), in some parts of India, China, Japan, and many other places in the tropics.

Elephantiasis is met with in all degrees of intensity, and it is quite impossible clinically to be sure when simple œdema ends and when solid œdema—i.e., lymphatic œdema with hypertrophy of the cutaneous and subcutaneous tissues—has commenced. The transition is generally gradual and insidious. The fact of primary importance in all stages of the disease is the lymphatic obstruction and œdema, and therefore we speak of the milder forms under the title "lymphatic œdema," whilst we reserve the name elephantiasis for the more extreme cases in which it is quite clear that hypertrophy of the connective tissue is present.

In the cases of elephantiasis met with in the tropics it is common to find a parasitic worm—the "filaria sanguinis hominis," a minute nematode worm about the size of the human red blood corpuscle—in the lymph- and blood-streams, in lymphatic abscesses, and in exudations into the serous cavities of the persons affected. The filaria in these cases is the assigned cause of the disease.

In the sporadic cases we meet with in England, and those which occur in temperate climates generally, this parasite may be confidently excluded from the causes of either elephantiasis or lymphatic œdema; even giant proportions may be attained by limbs affected with elephantiasis owing its origin to traumatic or other simple non-parasitic causes.

MORBID ANATOMY OF ELEPHANTIASIS.

When, at a post-mortem examination, or after amputation, opportunity has been afforded to dissect and examine an elephantiasic limb, the pathological changes which have been found have been limited as a rule to the superficial structures—namely, the skin and subcutaneous tissue. A quantity of clear, yellowish-white fluid pervaded the tissue spaces and the glistening swollen fibrous or lardaceous-looking subcutaneous tissue; there was hypertrophy of the cellular and, to a less degree, of the dermic and epidermic tissues; and great dilatation of some of the lymphatic plexuses, and in some cases of the more superficial veins, was observed. Rarely were the lymph nodes or glands enlarged or altered. Microscopically the lymphatic vessels were choked with cells, and large numbers of cells were accumulated outside the vessels. Some of the lymphatic tubes were converted into fibrous cords. The exuded lymph has been found in process of organisation towards fibrillation, and the dermic and epidermic structures as well as the cellular tissue were seen to be undergoing real hypertrophy. In rare instances the muscles have been undergoing fatty degeneration, or the bones have been thickened or carious or necrosed; but excepting when the starting point of the lymphangitis to which the œdema was due has been disease of a joint or bone, and the muscles have become atrophied and degenerated from non-use, nothing abnormal has been found beneath the deep fascia.

ABSENCE OF LYMPHATIC PLEXUSES IN MUSCLES.

We must associate this last fact with the absence of any capillary lymphatic network in muscular tissue generally. Though lymphatic plexuses are rich and abundant on the tendons, and though lymphatic ducts, it is true, pass through muscles, yet in the muscle tissue proper, where the blood-supply is particularly abundant, there are no lymphatic capillaries.

In the case of the pectoral muscles this fact has special importance in connexion with cancer of the breast. Though it is unquestionable that lymphatic ducts course through the great pectoral muscles to reach (1) the axillary, (2) the subclavian, and (3) the internal mammary chain of lymphatic glands, it is more than probable that the only lymphatic capillaries associated with muscles are those of the tendons. For this reason, and because we now know that cancer spreads along the lymphatics by a process of permeation by actual growth, rather than by the mere transit of cancer cells along the lymph stream, which till recently was regarded as the only way of extension or metastasis—for these reasons, I say, the ruthless and routine removal of the pectoral muscles without regard to the particular anatomical relations of the growth, which is commonly now practised in operations for mammary carcinoma, is often as useless and unnecessary as it is rash and severe. Into this question, however, I must not now digress, especially as I have somewhat lately published my views upon it in my "William Mitchell Banks" lecture.

WHY JOINTS STIFFEN IN LYMPHATIC ŒDEMA.

One last remark in connexion with the anatomy of the lymphatics I will add. I think we can see that in the richness and abundance of the lymphatic plexuses in connexion with the tendons of muscles we have the explanation of the drop-foot and the rigid and immobile digits whether of the foot or hand. Naturally, where the reticular arrangement of the lymphatic capillaries is most abundant, there we should expect to find the freest exudation if the lymphatics are obstructed, and, as the disease advances, the greatest hypertrophy of tissue; and as a consequence of abundant exudation about the tendons, there will ensue resistance to their free action and stiffening of the joints upon which they normally act.

CONDITIONS SIMULATING ŒDEMA.

In conclusion, and by way of a postscript, I want to refer to a remark I made at the beginning of this lecture. I said a mere glance convinced one as to the presence of œdema. But can we always so easily satisfy ourselves? Can we always be sure from mere appearances that the swelling is due to œdema? Though the diagnosis of lymphatic œdema will rarely be difficult, it may be mistaken for hypertrophy of the skin as in scleroderma, or for excess of subcutaneous fat. Unless scleroderma commences as a true lymphangitis of the most superficial lymphatics, followed by rapid effusion (and then the two diseases are essentially the same), there is no pitting of the skin. Neither is there pitting in cases of overgrowth of the subcutaneous fat. The cyanosis of the skin when present is caused by obstruction to the flow of blood in the venous radicles due to the pressure upon them by the exuded lymph. The integument in some cases is described as having been of a dark brown colour, and the bronzing of the skin as having suggested Addison's disease.

The Hunterian Lectures

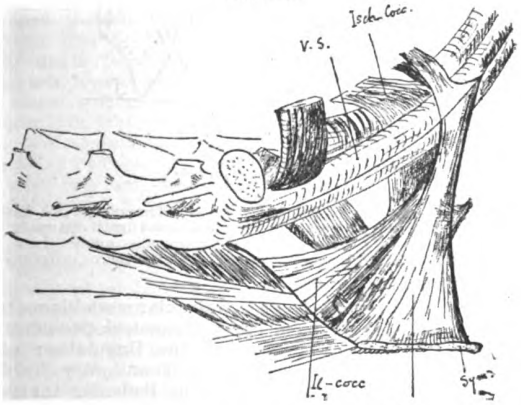
ON

THE EVOLUTION OF THE PELVIC FLOOR IN THE NON-MAMMALIAN VERTEBRATES AND PRONOGRADE MAMMALS.

Delivered before the Royal College of Surgeons of England on March 4th and 7th, 1910,

BY R. H. PARAMORE, M.D. LOND., F.R.C.S. ENG.

LECTURE II.*—PRONOGRADE MAMMALS.



Delivered on March 7th.

THE PELVIC FLOOR MUSCLES.

In Carnivora and Pronograde Primates.

MR. PRESIDENT, LADIES, AND GENTLEMEN,—In the great majority of terrestrial mammals the three pairs of muscles connecting the pelvis with the tail, and which we have hitherto spoken of as the antero-posterior and the lateral caudo-pelvic muscles, but which in mammals are known as the pubo-, ilio-, and ischio-coccygeus, are represented; and, with the tail and the superficial sphincteric layer, form an effective closure of the pelvis. In some, as the Carnivora and Pronograde Primates, these pelvic floor muscles exist as well-developed muscular sheets, disposed in two layers on each side of the pelvic cavity—an inner layer, consisting of the pubo- and ilio-coccygeus, which in man together form the levator ani muscle, and an outer, the ischio-coccygeus, representing the coccygeus of human anatomy. Of these the pubo-coccygeus and the ilio-coccygeus form a continuous sheet, the posterior margin of the one being contiguous with the anterior margin of the other, so that more or less difficulty may be experienced in differentiating the interval between them, and which is not always accurately defined by the passage of the obturator nerve (Fig. 10). The pelvic

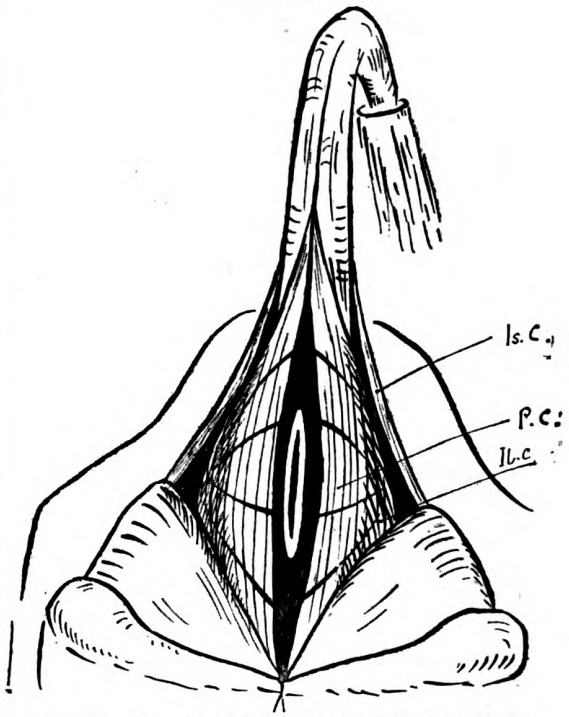


FIG. 10.

Dissection of the pelvis, showing pelvic floor muscles of a dog (fox-terrier) from within, about half life-size. P.C., Pubo-coccygeus muscle. Il.-cocc., Ilio-coccygeus muscle. Isch.-cocc., Ischio-coccygeus muscle. V.S., Ventral sacro-coccygeus muscle.

line of attachment extends along the internal aspect of the symphysis of the pubis in the whole of its extent, and along the ilio-pectineal line as far dorsally as the sacrum. From this wide origin the fibres converge as they pass upwards and backwards to reach the root of the tail, into the ventral mid-line of which they are inserted. At this insertion the ilio-coccygeus ends in a fascial strand, which is placed lateral to the pubo-coccygeus. Thus these two muscular sheets, one on each side, together form a funnel-shaped closure to the pelvis, which leads from the abdominal cavity to the perineal region, and which ends at the outlet as a vertical slit, formed by the most posterior fibres of the pubo-coccygei. At their origin and insertion these are attached to the mid-line, and thus are in apposition with each other, and in their course are only separated by the rectum and urogenital passages, which quit the pelvic cavity by passing between them (Fig. 11). To the outer side of

FIG. 11.

this internal layer is the ischio-coccygeus, which also forms a conspicuous layer, the breadth of which varies in different species. It arises from the ischial spine and adjacent bone, and is inserted into the lateral aspect of the root of the tail, separated from the caudal attachment of the pubo- and ilio-coccygeus by the ventral sacro-coccygeus.

In Rodents.

In the Rodents the pubo- and ilio-coccygeus are, as a rule, not well developed, and are not comparable to the homologous muscles in Carnivora and Primates. They exist as thin muscular sheets, which arise from the anterior part (only) of the symphysis pubis and the adjacent part of the

antero-lateral pelvic wall (brim), and are inserted into the tail, not as a rule into the median line, at least not with that precision found in the Carnivora and Pronograde Primates,

* Lecture I. was published in THE LANCET of May 21st, p. 1393.

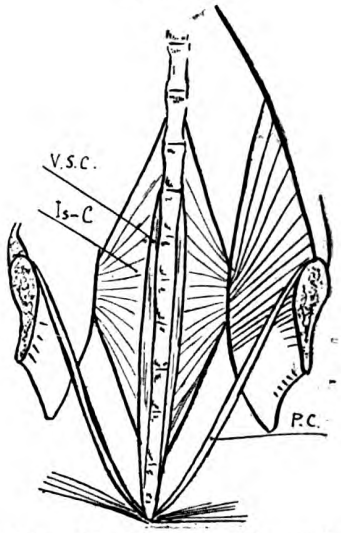
although some of their fibres may be traced into it, but usually ending in the fascia covering the ventral sacro-coccygeus, and more often towards its lateral aspect (Fig. 12). In some species the ilio-coccygeus appears to be altogether absent, or, according to some, is incorporated with the distal part or border of the ischio-coccygeus, as in

FIG. 13.

Dissection of the pelvis of the rabbit. The symphysis has been divided, the right innominate bone turned outwards, and the left removed, leaving ischial spine. Life size. Is.-c., Ischio-coccygeus muscle, v.s., Ventral sacro-coccygeus muscle. x, So-called ilio-coccygeus muscle; this is inserted into mid-line of the tail, being thus separated from the caudal attachment of the ischio-coccygeus by the ventral sacro-coccygeus.

the rabbit (Fig. 13). In others, as the Squirrel, both the pubo- and ilio-coccygei are well developed.

The ischio-coccygeus in the Rodents is usually conspicuously present. It exists as a wide muscular sheet, as a rule quite distinct from the other muscles, and placed on their outer aspect. Often it is fan-shaped, as in the rabbit, arising from the ischial spine and passing inwards, its fibres radiating widely to be inserted into the proximal coccygeal vertebræ by an extensive insertion. In the tree-climbing and brush-tailed porcupines the muscle is remarkably developed. Its origin is not limited to the ischial spine, but it extends along the pelvic outlet, reaching almost to the symphysis. From these wide origins the fibres spread as they pass to the tail, forming thick and broad strata, clearly of considerable strength, and are inserted by still more extensive attachments. The pubo-coccygeus in each is an insignificant looking, thin sheet of muscle. An ilio-coccygeus cannot be distinguished.



In Ungulates.

In yet other mammals—the large group of ungulates—the pubo- and ilio-coccygeus are entirely absent, and the ischio-coccygeus is the only muscle of the group occurring; but, unlike the muscle in the majority of the rodents, it does not form such an extensive sheet. In the horse (Fig. 18) it arises from the ischial spine by a fascial aponeurosis, and passes as a thick, strap-like muscle upwards, inwards, and slightly backwards, to be inserted into the root of the tail. The manner of its attachment in the horse is interesting, for at its insertion it splits into two laminæ; the outer, much the larger, passing upwards external to the ventral sacro-coccygeus, to be inserted by two slips into the transverse processes of the second and third coccygeal vertebræ; the median, or ventral lamina, smaller, passes inwards around the ventral sacro-coccygeus, and is inserted in the middle line into the fourth coccygeal vertebra. From the relation of these two parts of insertion to the ventral sacro-coccygeus we may perhaps speculate so far as to say that whilst the larger lateral insertion may be regarded as the ischio-coccygeus proper perhaps the ventral slip represents all that is left of a muscle, corresponding to the so-called ilio-coccygeus of the rabbit, which may have become fused with the ischio-coccygeus to a greater extent than it has done in that rodent, for in both its caudal attachment is separated from that of the ischio-coccygeus by the ventral sacro-coccygeus. In the Panolin Deer (Cervus Eldi) the disposition of the ischio-coccygeus is similar to that of the horse, except that no slip leaves the muscle to pass around the ventral sacro-coccygeus to be inserted into the median line.

In Hyrax.

The condition in Hyrax is exceedingly interesting (Fig. 14).

FIG. 14.

Dissection of the pelvis of the Hyrax. The symphysis has been divided and each innominate bone turned outwards. About double life size. P.C., Pubo-coccygeus muscle. Is.-c., Ischio-coccygeus muscle. v.s.c., Ventral sacro-coccygeus muscle.

Although this species bears "a singular resemblance to the Rodents" (Beddard), from other anatomical peculiarities it is placed by zoologists amongst the Ungulates; and is indeed considered to be a survival from antiquity (Beddard). It has no free tail; and, as in the Rodents, the ischio-coccygeus is well-developed, and exists as a fan-shaped muscle arising from the ischial spine, its fibres spreading out as they pass inwards to be attached by a wide insertion into the remaining coccygeal vertebræ—thus forming, with these vertebræ and the muscle of the opposite side, a dorsal wall for the pelvic cavity. The ilio-coccygeus appears to be entirely absent; and in the specimens I examined I found no evidence of a muscle, situated along the posterior border of the ischio-coccygeus, corresponding to the so-called ilio-coccygeus of the rabbit or to the ventral slip found in the horse. A pubo-coccygeus, however, is present, and is represented by a narrow and slender band of muscle, which arises from the crest of the pubis, and is inserted into the distal extremity of the vertebral column.

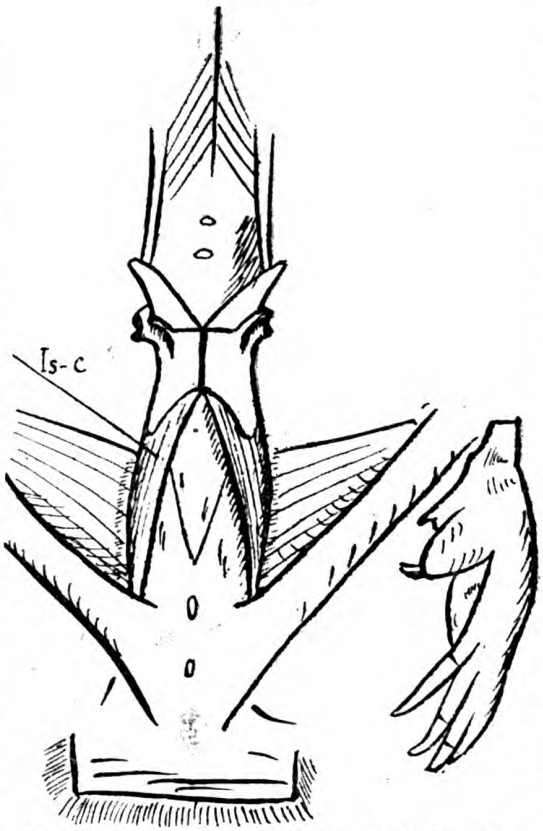
If Hyrax is a representative of an ancient form of ungulate the presence of this diminutive yet plainly muscular pubo-coccygeus points to the existence of a similar muscle in the ancestors of the more common species of this order (ungulate), the earliest forms of which, according to Mr. Beddard, "are not by any means easily differentiated from

the primitive carnivorous mammals of that date, the Creodonta." If, therefore, the present-day Ungulates and Carnivora have come from a common stock, it is plain that the pelvic floor muscles in each, presenting such marked differences as they do, have deviated, in the course of evolution, from a common plan; and we can only suppose the changes in structure of the closing apparatus of the pelvis which have ensued have been caused by changes in habits and environment of the ancestors of the several individuals of these orders. These we must endeavour to understand, so that we may be able to appreciate the factors which have determined the existence of such an efficient closure in the Carnivora, on the one hand, and, presumably, a less effective mechanism for the maintenance of an internal pressure in the Ungulates on the other: a study which will teach us the function of the pelvic floor musculature in each.

THE TAIL AND ITS MOVEMENT.

In the foregoing survey we have described the pelvic floor muscles as arising from the pelvis and being inserted into the coccygeal vertebræ; whereas in the fish, amphibians and reptiles, we spoke of the caudo-pelvic muscles as arising from the tail and being inserted into the pelvis. This change in description is due to the fact that in the non-mammalian vertebrates the tail, at least in its proximal part, is rigid in the dorso-ventral plane, and is only freely moveable from side to side; whilst the pelvis, such as it is, with some exceptions (e.g., Crocodile), is moveable antero-posteriorly upon the sacrum. But in the terrestrial mammals, the tail, when present, is moveable in all directions, whilst the pelvis has become fixed, and thus we speak of these muscles as arising from the pelvis in mammals, since this is their more fixed attachment. There is, however, this important point to notice, that whereas in tailed amphibians and reptiles (Lacertilia), the caudo-pelvic muscles are attached to the tail at some considerable distance from the pelvis, so that they are either in the same straight line, or very nearly in the same straight line, as the recti abdominis muscles, the pull of which upon the pelvis they are thus able to counteract; in the mammals—Carnivora and Primates especially—the attachments of these caudo-pelvic muscles to the tail have crept towards its root, so that instead of being approximately in the same straight line as the recti they are placed almost at a right angle to them. The fixation of the pelvis to the spine has done away with the necessity of the earlier position of these muscles and permitted the evolution of a freely mobile tail, whilst the forcible voluntary apposition of the tail root against the perineal region—forming the perineal shutter of Professor Arthur Keith—only became possible, or, at least, was best effected, as the laws of mechanics demonstrate, by such a recession. With this mobility the intrinsic muscles of the tail are correspondingly developed, and consist of four sets of muscles, arranged longitudinally about its skeleton, two dorsal and two ventral—each dorsal and each ventral set disposed symmetrically on either side of the dorso-ventral plane. They arise from the sacrum: the upper from its dorsal aspect, where they appear to be the continuations of the longissimus dorsi of each side; the lower, from its ventral aspect. These sacro-coccygei pass distally along the tail, and are usually segmented; numerous muscle bundles arise from each vertebra to be inserted into the next, and so on to the extreme tip. Sometimes the sacro-coccygei end in long and slender tendons, which pass to the several vertebræ, as in the Lemuroidæ and Kangaroos; but even in these cases distinct muscles arise from each vertebra to be inserted into the next vertebra, all along the tail skeleton. These muscles are clearly evident in the Horse, the Dog, and the Monkey (Semnopethicus entellus), and in all the tailed mammals I have dissected. In the proximal part of the tail the dorsal set are, as a rule, more conspicuous than the ventral, presumably because of the action of gravity and of the caudo-pelvic muscles, both of which they have to counteract. They are the true tail-moving muscles, and by various combinations cause the tail to move in any desired direction.

It has been assumed, stated, and is, perhaps, almost generally believed, that movement of the tail in tailed mammals depends upon the activity—besides other muscles, such as the sacro-coccygei—of the pubo- and ilio coccygei, and of the ischio-coccygei, because these muscles arise from the pelvis and are attached to the tail; and on this assumption these muscles have been spoken of as "tail-moving" muscles, the pubo- and ilio-coccygei actually being called "flexors" and the ischio-coccygeus an "abductor." Further, the representation has been made that the prehensility of the tail in the case of the Tailed Apes and the rigidity of the tail in the case of the "Tripod" Kangaroo depend upon them. Whilst it is probably true that the contraction of the pelvic-floor muscles is increased when the tail is used as a prehensile organ, it seems rather strange to argue from this that they determine prehensility of the tail, for during any active movement whatever the contraction of the entire musculature of the body is increased in correspondence with the energy displayed in that movement. These pelvic-floor muscles are attached to the tail near its root, far away (two feet, Ateles †) from the distal, prehensile part, the grasping movement of which is, of course, effected by the intrinsic muscles. The representation that the pubo- and ilio-coccygei are responsible for this prehensility is all the more remarkable when it is known that only New World (American) monkeys, and not all these, display this faculty (Heilprin, Beddard, and others). Semnopithecus entellus, an Old World monkey, with a long and well-developed tail, has these pelvic-floor muscles extremely well developed, surely a remarkable condition of structure if these muscles determine prehensility of the tail; for in this monkey, as in all Old World monkeys, the tail is never prehensile.



As regards the statement that these pelvic-floor muscles are tail-moving muscles—that is, that they cause a movement of the tail, implying by that word what is generally understood—we may say that movement of the tail in the horse or in the cow is as free as, or is freer than, in the dog; and that the Ungulate has as much control of its movements as the Carnivora: but whereas the pubo- and ilio-coccygei are present in the latter (Carnivora), they are completely absent in the former (Ungulate). It is therefore plain that efficient movement of the tail does not depend upon the contraction of the pubo- and ilio-coccygei since it takes place in their absence. Moreover, both Ungulates and Carnivora possess well-marked ischio-coccygei; but these can have no effect whatever over the distal and most mobile part of the tail. (Figs. 17 and 15.)

Yet the ischio-coccygeus is supposed to be the abductor of the tail, and is called the "abductor caudæ." This supposed function is deduced from the attachments of the muscle; and it is supposed that when one contracts, whilst the other is inhibited, the tail will be abducted. That such contraction on one side and relaxation on the other would result in abduction may be readily granted, although in many cases the line of traction is such that the tail would be pulled more downwards than to the side; but that such unilateral contraction takes place has not been shown to occur. In the first place the attachments of the muscle are no certain guide to its function. "It is impossible," says Dr. Pembrey,[27] "to analyse movement in the living by an examination of the points of origin and insertion of the different muscles acting upon the joints of dead subjects"—an opinion which is widely accepted. It is just as reasonable to suppose that the two muscles, one of each side, always act together; that they are synchronously and synergetically innervated, just as we believe the tranversalis abdominis of each side, and the two halves of the thoracic diaphragm are similarly innervated, as it is to take for granted that they invariably react apart, as is supposed. Abduction of the tail can as well be effected by the intrinsic muscles of the tail as its movements of flexion and extension. Indeed, the lateral extension of the ventral sacro-coccygeus on to the lateral pelvic wall in Myrmecophaga appears to be for this very purpose; for the tail, which is bilaterally compressed, has a much more extensive range of movement from side to side than dorso-ventrally, at any rate in its proximal part. At least it will be admitted that the ischio-coccygeus does not act as an abductor of the tail in Hyrax or in the Guinea-pig, in both of which it is conspicuously present; for in neither does a free tail exist. In these mammals, as in many others, Rodents especially, in which the pubo- and ilio-coccygei are not well developed, the ischio-coccygei, forming, with the interposed coccygeal vertebræ, a dorsal wall for the pelvic cavity,

† See specimen in Zoological Society's Gardens.

play a part in the maintenance of the pressure within; just as the transversalis and thoracic diaphragm play the chief part in the production of that pressure. This is supported by finding that in Ornithorhynchus (Fig. 15), in which, moreover, movement of the tail is more or less limited to the dorso-ventral plane, and in such Rodents as the Porcupines the ischio-coccygei have very extensive origins and insertions; in these species they plainly cause a similar occlusion of the pelvic outlet by an approximation of the root of the tail to the perineum, as is determined in other mammals by the pubo- and ilio-coccygei, for which end the muscle of each side of necessity must contract together. In the Carnivora and Pronograde Primates the ischio-coccygei are auxiliaries to the same end; and whilst it cannot be denied that they may act individually as abductors—for the negative requires to be shown as well as the positive—there is very good ground for the opinion that this abduction is but a secondary, unimportant, and perhaps not actually occurring function.

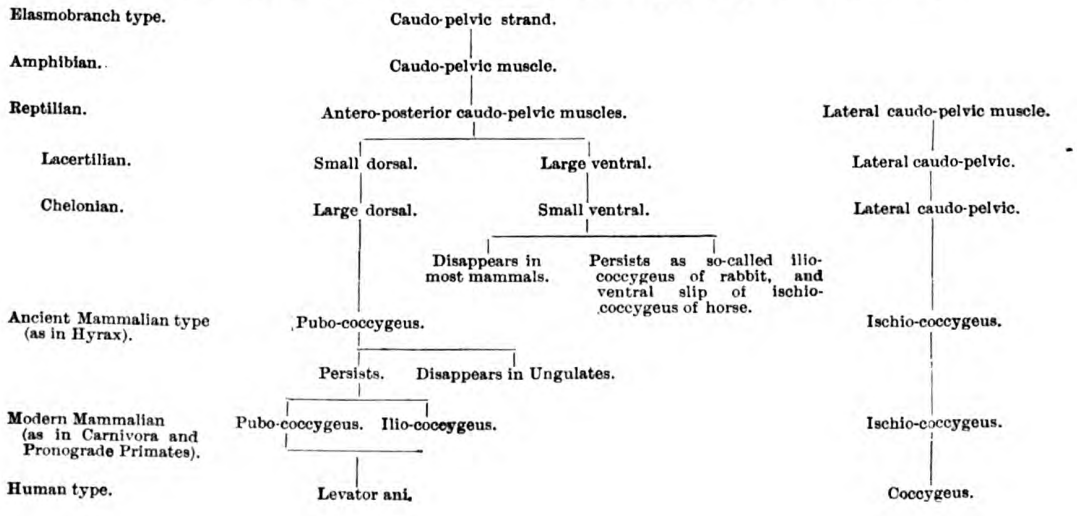


FIG. 15.

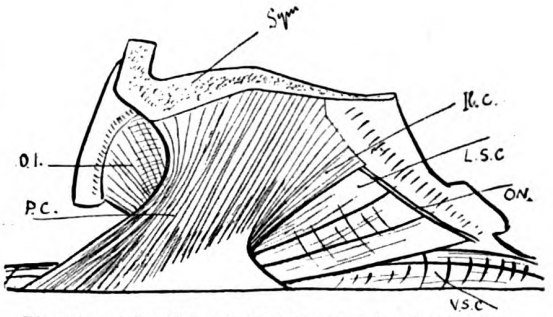
Dissection of posterior end of body of Ornithorhynchus, vertical view showing Is.c., the ischio-coccygeus muscle. Scale about life-size.

In this place may be completed what is to be said concerning the fallacious assumption that the function of the pelvic floor muscles is to move the tail. From this assumption it is argued that because these muscles in tailed mammals are tail-moving, when the tail degenerates these muscles, too, must degenerate, just as the muscles of a limb atrophy when the joint they should move becomes ankylosed. Since, therefore, in man the tail has degenerated, it is further argued that the homologues of these tail-moving muscles, such as they are, which he may possess, have also degenerated; that they are indeed but vestigial structures. The argument is sound but the premises are false. That the argument is sound is shown by the fact that the representatives in man of the true tail-moving muscles of tailed mammals have in him, with the loss of his tail, verily degenerated; but they are not the pelvic floor muscles, they are the sacro-coccygei; for the former, although they have undergone considerable changes, are still remarkably developed. That the function of the pelvic floor muscles is not to move the tail *per se* is shown by their evolution in the fish, amphibians and reptiles (lizards and crocodiles), which are not able to flex the tail; in these they serve to fix the pelvis, and to play a part in the production and maintenance of a frequently recurring increased visceral pressure. That they play the same part in mammals is not hard to divine, and is a sufficient reason for the discovery that, in spite of a degenerate tail, in man they still function. In tailed mammals, however, they do this in one of two ways, either by drawing the root of the tail against the perineum, or else, when the tail is maintained extended by the dorsal sacro-coccygei, by a simultaneous increase in their contraction. These actions are comparable to a backward displacement or fixation of the pelvis in the fish, amphibians and reptiles; but it would surely be a misnomer to call the caudo-pelvic muscles in these vertebrates "pelvis-moving" muscles; and similarly, to describe the muscles in mammals which cause this movement of the root of the tail as tail-moving muscles, whilst true in the narrow sense that their activity may cause, and does cause, a movement of the root of the tail, is, in the wider sense, anything but a true representation of the conditions which actually exist. It is, indeed, to this faulty application of words that the erroneous conclusion has been come to that the pubo-, ilio-, and ischio-coccygei in man have degenerated past functioning because his tail has disappeared.

THE HOMOLOGY OF THE CAUDO-PELVIC MUSCLES.—*Phylogeny of Pelvic Floor Muscles.*

THE HOMOLOGY OF THE CAUDO-PELVIC MUSCLES.



That the antero-posterior and the lateral caudo-pelvic muscles in reptiles are homologous with the pubo- and ilio-coccygei and the ischio-coccygei of mammals is, of course, difficult, or perhaps impossible, to prove. No one, however, can examine the muscles which close the pelvic outlet in such reptiles as Iguana, Emys, and Testudo, and in such mammals as the Dog, Rabbit, Kangaroo, the Monotremes, and Hyrax, and fail to notice the remarkable correspondence which occurs in their attachments, and especially in their relations to such other muscles as in mammals are known as the pyriformis, the obturator internus, and the ventral sacro-coccygeus.

There can be little doubt that the caudo-pelvic muscles in Menobranchus and Salamander maculosa, and the antero-posterior caudo-pelvic muscles in Iguana and Emys, are all homologous; but whilst in the former (amphibians) these consist of a single belly on each side, in the latter a differentiation into two distinct muscles has occurred. The more dorsal of these in Iguana is much the smaller, and appears, from the resemblance of the other much larger muscle to the caudo-pelvic muscle of amphibians, to be a new element segmented off from it. In Emys, this new muscle has become much larger; but instead of passing obliquely forwards and outwards it passes directly forwards to be inserted into the pelvic brim (pubis), passing above the ventral part of the pelvis and above the muscle arising from this part, which appears to be the homologue of the obturator internus, and which in Iguana similarly separates the two antero-posterior caudo-pelvic muscles at their insertions. It seems as though the necessity for a more efficient closing apparatus for the pelvis in Emys has caused the pelvic attachments of both the antero-posterior muscles to shift from their lateral position in Iguana to the more median position in Emys; and that whilst the more dorsal and smaller muscle in Iguana has crept inwards along the pubic bone—i.e., pelvic inlet—the more ventral and larger muscle in Iguana has crept inwards along the pelvic outlet, the two being thus separated by the (?) obturator internus, the presence of which perhaps determined the direction adopted by each. With the transposition inwards, a change in size has occurred: the former muscle, small in Iguana becoming larger in Emys; and the latter, conspicuous in Iguana becoming quite diminutive in Emys. In Testudo, this small ventral caudo-pelvic muscle of Emys has disappeared entirely, and the other antero-posterior caudo-pelvic muscle—much enlarged—is the only one present. From a comparison of this antero-posterior caudo-pelvic muscle of Testudo with the similarly disposed pubo-coccygeus of Hyrax, it seems fairly clear that the two muscles are homologous. If this be so, we must regard the pubo-coccygeus of Hyrax as representing an ancient type of the mammalian pubo-coccygeus, which, on the one hand, has developed into the more extensive muscle of Carnivora, and on the other, has suffered suppression as in the Ungulates.

It has been supposed that the pubo- and ilio-coccygeus have evolved by a lateral extension of the fibres of origin of a primitive flexor muscle of the tail, placed along the ventral surface of the sacrum and coccygeal vertebræ; and that these crept along the lateral pelvic wall towards the pubic symphysis, so that, according to this conception, the pubic fibres, presumably, are the last instead of being the first, as the condition in the Tortoise teaches, to appear. If the pubo-coccygeus itself has arisen from the antero-posterior caudo-pelvic muscles of reptiles and amphibia, it clearly cannot have arisen from a ventral sacro-coccygeus, because the ventral sacro-coccygeus does not occur in the amphibia and Lizards and Crocodiles, and only first appears in the tortoise as the tail became moveable dorso-ventrally.

That a lateral extension of the ventral sacro-coccygeus on to the adjoining pelvic wall may occur, however, is shown by its having happened in the Kangaroo and Myrmecophaga—the condition in which two species has been advanced as representing an intermediate stage in the evolution of the pubo- and ilio-coccygeus from the primitive sacro-coccygeus. But this lateral extension of the ventral-sacro-coccygeus, which in the Wallaby (Fig. 16) consists of numerous muscular bellies all ending in long tendons (in my specimen 17 at least on each side) seems to be easily and sufficiently explained by the large development of the muscle necessary in the Kangaroo for the fixation of the tail which is used as a support for the body, the lateral parts of the muscle, owing to the relatively small size of the pelvic cavity and narrowness of the sacrum, having been crowded on to the lateral pelvic wall (ilium and ischium)—an extension which is readily intelligible. It is obvious that in virtue of this lateral extension the muscle can more efficiently fix the tail upon the pelvis and give it rigidity, just as the similar lateral extension in Myrmecophaga allows this part to act to the best advantage as an abductor of the tail.

FIG. 16.

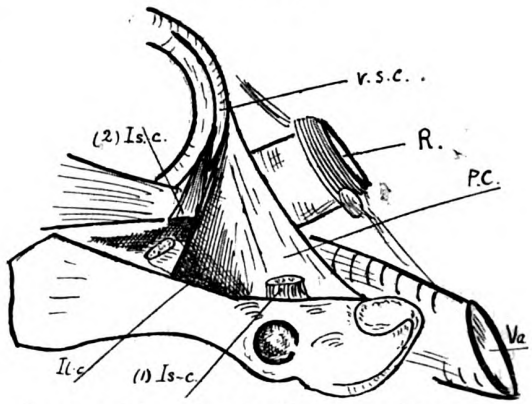
Dissection of the pelvis and pelvic floor muscles of a Wallaby. The vertebræ are not shown. Rather less than half size. Sym., Symphysis. O.I., Obturator internus muscle. P.C., Pubo-coccygeus muscle. Il.c., Ilio-coccygeus muscle. L.S.C., Iliac origin of the ventral sacro-coccygeus muscle. V.S.C., Sacral origin of the same. O.N., Obturator nerve.

That the lateral extension of the ventral sacro-coccygeus on to the lateral pelvic wall in the Kangaroo and in Myrmecophaga is not an intermediate stage in the evolution of the ilio-coccygeus in these animals is further shown by the fact that the anterior fibres of the pubo-coccygeus in both species are more obliquely placed than the posterior, and towards their caudal attachment overlap the posterior fibres, so that at their insertion they are placed laterally to them—just as in the Carnivora the ilio-coccygeus at its caudal attachment overlaps and lies lateral to the attachment of the pubo-coccygeus. Indeed, it seems that these anterior fibres really represent the beginnings of the ilio-coccygeus, which apparently has no homologue amongst the non-mammalian caudo-pelvic muscles—that is to say, that the ilio-coccygeus arises as a part segmented off from the more primitive mammalian pubo-coccygeus, the fibres of which, as they grow dorsally along the lateral pelvic wall, creep laterally rather than mesially to the obturator nerve—which may explain the fact that often this nerve pierces either the pubo- or the ilio-coccygeus (Holl), rather than passes through the interval between them. This hypothesis is supported by the fact that these muscles are always closely connected together, in many cases their complete separation being artificial; and, further, that in many rodents in which the pubo-coccygeus is relatively insignificant an ilio-coccygeus is apparently completely absent (as in Porcupine).

The proximal part of the ventral sacro-coccygeus, by flexing the root of the tail, may act as an accessory to the pelvic floor muscles; and this may explain its existence in the short-tailed Echidna and in the tailless Guinea-pig and Hyrax, but compared with the pubo- and ilio-coccygeus it is clearly at a disadvantage for such a purpose because of the more ventral attachment to the pelvic brim of these muscles.

That the lateral caudo-pelvic muscle of reptiles (Tortoise) and the ischio-coccygeus of mammals are homologous is not unlikely, for each arises from the lateral aspect of the tail, immediately dorsal to the ventral sacro-coccygeus, both in the tortoise and mammal. It is, however, impossible to trace the transition of these muscles from the reptilian to the mammalian plan since the material is not forthcoming, but it is known that the ischial symphysis separates, and thus we may suppose that as it does so the muscles inserted medianly into it become displaced laterally with each half. In the Monotremes this separation of the ischial symphysis is not complete, and in Ornithorhynchus the pelvic attachment of the ischio-coccygeus reaches ventrally quite up to, or almost up to, the symphysis, a condition which closely resembles the pelvic attachment of the lateral caudo-pelvic muscle in Testudo. (Compare Fig. 9, Lecture I., and Fig. 15,

Lecture II.) As flexion of the tail root became possible the sphincteric mechanism effected by the two lateral caudo-pelvic muscles in the reptiles was no longer so necessary, and thus their median ventral insertions were allowed to diverge, but instead they served as a powerful means of approximating the root of the tail to the pelvic outlet, and this explains their marked development in the monotremes, marsupials, and rodents. All these changes, presumably, were caused by the necessity for the frequent occurrence of considerable variations of the internal pressure, which are greatest in mammals of all vertebrates because of the presence of the thoracic diaphragm, to which pressure conditions alone can be attributed the extension of the ischio-coccygei anteriorly and their retention in such tailless species as Hyrax and the Guinea-pig.



Further support of the hypothesis that the lateral caudo-pelvic muscle and the ischio-coccygeus are homologous is afforded by the presence of the so-called ilio-coccygeus in the rabbit, for this muscle is intimately associated with the ischio-coccygeus at its origin from the ischium, and part of it is inserted into the mid-line of the tail and is thus separated from the ischio-coccygeus by the ventral sacro-coccygeus. If we can imagine the ischial attachments of the muscles of each side in the rabbit displaced ventrally and inwards around the pelvic outlet so as to meet in a median ventral symphysis, and if the caudal attachments of the muscles were displaced distally along the tail into the reptilian position, we should have the condition in Emys exactly reproduced, the so-called ilio-coccygeus of the rabbit corresponding in position to the small ventral antero-posterior caudo-pelvic muscle of Emys and the ischio-coccygeus to the lateral caudo-pelvic muscle; for the relation of the two muscles to each other in Emys at their insertion into the ischial symphysis is very intimate, and is exactly comparable to the relation of the two muscles at their origin from the ischium in the rabbit. Lartschneider [21] has stated that this so-called ilio-coccygeus of the rabbit is a part of the ventral sacro-coccygeus, which he supposes has deviated laterally from its original median position on to the ischium, from which in other (and past) species it crept up the lateral pelvic wall to ultimately reach the brim and so to become the ilio-coccygeus of mammals; but he brings forward no reason to show why it should have done so, and the only evidence he adduces in support of his statement is the fact of the lateral deviation of the ventral sacro-coccygeus in Myrmecophaga and the Kangaroo, which he says represents intermediate stages in this transition, but which we have already seen can be otherwise explained. Others have assumed that this so-called ilio-coccygeus of the rabbit has descended from the pelvic brim from a supposed primary lateral extension of the sacro-coccygeus, comparable to the descent of the muscle which has occurred in man; but this seems to me to be fallacious, for there is no evidence that the factors which have caused the descent of the ilio-coccygeus in man—factors which are dependent upon the assumption of the erect posture—have existed in the rabbit. The condition in Emys seems to be the key to the understanding of these muscles, and, if so, demonstrates that the so-called ilio-coccygeus in the rabbit is homologous with the small ventral antero-posterior caudo-pelvic muscle of Emys and not homologous with the ilio-coccygeus of Carnivora and of other Rodents (as the Squirrel), and that the lateral caudo-pelvic muscle of Reptiles and the ischio-coccygeus of mammals are homologous.

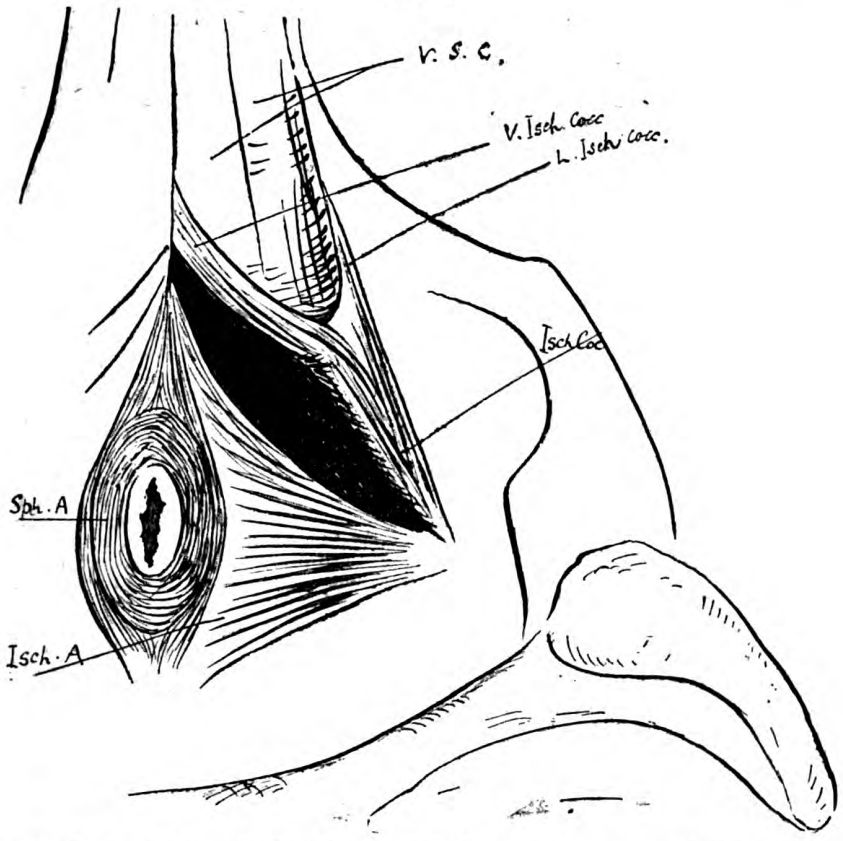
THE SPHINCTERIC LAYER.

The superficial sphincteric layer of muscles, guarding the anal and urogenital orifices, is universally present in mammals; but presents wide variations in development and extent in different orders. As a rule, we may say that in those animals in which the closure of the pelvis is efficiently effected by the pubo-, ilio-, and ischio-coccygei, the sphincters exist, usually well developed, but merely as closing mechanisms for the orifices they surround; whilst in others, in which the pelvic floor muscles are either not so well developed or not so efficient, the superficial muscular layer not only forms sphincters for the orifices but in many cases, gaining extensive attachments to the pelvic outlet, plays a part in the maintenance of the internal visceral pressure. Thus in the Carnivora and Pronograde Primates the sphincters are well developed; but, often—as in the dog (Fig. 17)—are placed some considerable distance beyond the slit-like orifice formed by the posterior fibres of the pubo-coccygei (Lartschneider), and thus there is no connexion between them.

In the Rodents, in which the pubo-coccygei are not so well developed as in Carnivora, the superficial sphincteric layer is much more marked; especially in those species in which the ischio-coccygei do not compensate sufficiently to take their place. In the Rabbit and Guinea-pig, for instance, this superficial layer is conspicuously present.

FIG. 17.

Dissection of the pelvis and pelvic floor muscles of a dog (fox terrier) from without. About half life-size. P.C., Pubo-coccygeus muscle. Il.-c., Ilio-coccygeus muscle, Is.-c., the ischio-coccygeus, cut through (1) the lower part, (2) the upper part. v.s.c., Ventral sacro-coccygeus muscle. R, Rectum surrounded by sphincter. Va, Vagina.



In the Ungulates, with the complete absence of the pubo- and ilio-coccygei, we find not only the sphincteric muscles remarkably developed, but also an ischio-anal muscle present which is almost as well developed as the ischio-coccygeus itself (Fig. 18). This muscle arises from the region of the ischial spine and is inserted into the terminal part of the rectum, in close association with the external sphincter muscle; some of its fibres, with some of the external sphincter muscle, are inserted into the tail; and others pass ventrally to the perineal region. According to Professor P. Thompson,[34] the ischio-anal represents a greatly developed transversus perinei muscle, and has evolved from the primitive sphincter of the cloaca. The ischio-anal of each side and the external sphincter ani together form a powerful tripartite musculature by means of which the internal pressure is safeguarded even in the absence of the pubo- and ilio-coccygei.

In Aquatic Mammals.

The sphincteric muscles are also well developed in marine mammals (Whales, Dolphins and Seals, &c.)—a condition which contrasts with their absence in non-mammalian aquatic vertebrates, and is apparently correlated with the terrestrial type of respiration and circulation, and the presence of a thoracic diaphragm. It is clear the pressure within the thorax must be less than the pressure outside the animal exerted by the medium (water) by which it is surrounded, for its lungs are of delicate structure and their blood capillaries thin-walled, so that if the air were maintained within the chest by an occlusion of the glottis only, and subjected to the pressure exerted on the rest of the viscera by the medium from without, as obtains in non-mammalian aquatic vertebrates, an obstruction to the circulation of the blood through the lungs would certainly result with consequent asphyxia ‡ This excessive pressure is prevented by

‡ The essential difference between the mammalian and those non-mammalian aquatic vertebrates which possess lungs—i.e., from Dipnoi upwards—is that whilst the blood flowing to the heart can only reach the aorta by passing through the lungs in mammals, owing to the fact that the right side of the heart does not communicate with the left side because of the growth of the interventricular septum and to the fact that the primitive efferent vessel has been completely divided into the pulmonary artery and aorta, in the non-mammalian vertebrates, this condition of the heart not having been reached, there is a free way for venous blood to the primitive aorta, so that only a portion of it passes through the lungs, whilst its adequate oxidation is provided by the possession either of internal or external gills, to which the blood passes by branches which arise from the aorta. This mechanism of respiration is not necessary in the terrestrial, non-mammalian vertebrate, because, presumably, the pressure exerted on the lung capillaries by the medium (air) is much less in these than in aquatic ones in which the pressure is

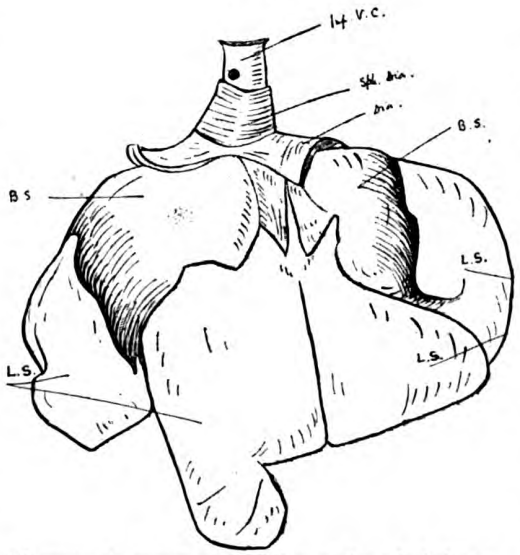


FIG. 18.

the bony walls of the thorax and by its musculatures, of which the thoracic diaphragm plays a conspicuous part, for it has, so to speak, to prevent the weight of the water bearing upon the abdomen from being transmitted by the visceral mass to the thoracic viscera and from causing an obliteration of the lung capillaries. This it does by its tonic contraction, in correspondence with which we find the diaphragm in these aquatic mammals exceedingly well developed, the central tendon itself being replaced by muscular tissue. Since, however, this visceral mass is permeated by a vascular system in free communication with the thoracic viscera, it is plain the weight of the water without and the increased contraction of the diaphragm within will tend to drive the blood from the abdomen into the thorax, because the pressure there is less, which would result in a congestion of the lungs. This is prevented by the development of that part of the diaphragm immediately surrounding the passage of the inferior vena cava into a definite sphincter-like mechanism, which by its contraction regulates the amount of blood entering the chest from the abdomen and causes a damming up of the blood within the abdomen, as is shown by the development of huge venous sacs within the liver. This sphincteric action upon the inferior vena cava and the pressure exerted by the rest of the diaphragm upon the abdominal contents is therefore very considerable, and must be at least equal to that exerted upon the animal from without. Thus the pressure conditions prevailing within the abdomen of marine mammals approach those occurring in terrestrial mammals—in which the pressure within the abdomen, except perhaps during recumbency and sleep, is always greater than the pressure without (atmospheric pressure)—and during such active expiratory acts as spouting is probably considerably increased. These considerations seem to explain the reason for the existence of the sphincter muscles in aquatic mammals; they are well marked in the Whale (Struthers[32]), and in the Dolphin are connected with

sufficient to necessitate another kind of breathing (ext. gills), because in them no muscular diaphragm is present to relieve by its contraction the lung capillaries from this obliterating pressure.

the rudimentary pelvis by muscles similar to the ischio-anal muscles of Ungulates.[35]

This sphincteric condition of the diaphragm upon the inferior vena cava, and the presence of the large blood sacs in the liver of the Walrus, have already been described by Mr. Burne, and are beautifully shown in a specimen taken from a seal, which is preserved in the Museum of the Royal College of Surgeons of England and which the same author recently exhibited before the Zoological Society (Fig. 19). The existence of these remarkable modifications of structure can only be explained by the aquatic habits of these animals; and they bring home to us the important and far-reaching influence which the pressure conditions within the abdomen exercise, for in these animals one of its effects at least is gross and obvious.

THE FACTORS AT PLAY IN THE EVOLUTION OF THE PELVIC FLOOR.

If now we come to ask ourselves how it is these different orders of mammals present such striking differences as regards the structure of the closing apparatus of their pelves, in all of which an efficient closure exists, the various conditions at first sight seem inexplicable. Yet a certain order obtains, so that by an examination of a dissected pelvis it is possible to say from what sort of animal it came. And if we turn our eyes from the specimens before us to the natural history of the individuals to which they belong, we find corresponding and remarkable differences—differences which are specific and vital, upon which the preservation of the individual species depends.

Let us consider the Ungulates and Carnivora, and ask ourselves, How do they compare with each other? and, How being neighbours, living side by side, do they manage to exist?

The Ungulates are vegetarians: this is such a distinguishing feature that they are called "Herbivora." They are ill-adapted for attacking, for striking, for killing, for devouring other animals, for the simple reason that these accomplishments form no necessary part of their being, and because of their comparative defencelessness they usually roam in herds or else seek security in solitary and often mountainous places. What means of attack they possess is for the purpose of defence, for the preservation of themselves and their young in times of great peril, or is but the outcome of pure savagery, and is never for the obtaining of food. In the other the essential characteristic is that they are flesh eaters; this is so significant of them that they are called "Carnivora." The ancestors of the former obtained their food from the succulent vegetation of primeval forests (cf. Tapirs) and subsequently by grazing on prairies (cf. Horses); the ancestors of the latter, by preying upon other animals, of which the most suitable as victims, because of their comparative defencelessness, were the ancestors of the present-day Ungulates (and Rodents). Thus it was determined the former should be hunted because the latter became hunters and preyed upon them. The preservation of the former from their flesh-eating opponents could only be effected by escape, and this necessitated the individuals should be capable of rapid and prolonged flight, to which their whole structure is splendidly adapted. Thus they came to use their limbs for progression only, which have become proportionately longer, so that they could cover the ground more rapidly, and unnecessary parts, such as (the possession of) several digits, necessary for clawing or grasping, have been suppressed. They acquired an easy and unobstructed respiration, essential for speed, conditioned by a wide larynx (Sir Lauder Brunton §), an easily expanding thorax, and by a continual avoidance of all movements, such as striking, which by determining a marked increase of pressure within the abdominal cavity necessitates a holding of the breath. Thus their power of vocalisation is poor, for it is impossible to utter loud and continuous sound without a considerable and correspondingly prolonged increase of intra-abdomino-pelvic pressure, which implies a fixation of the abdomen as well as of the thorax, and the necessity to do this frequently and efficiently is conditioned by the possession of good musculatures enclosing the visceral mass. The horse indeed neighs, but rarely; the bull bellows, but infrequently. These are curious sounds, apparently not easily produced, and perhaps their peculiarity depends upon this difficulty; they are scarcely comparable to those omitted by the Carnivora (cf. Dog ‖), which in this way intimidate their prey (or their opponents), and thus gain an easier victory; but the Ungulates require no such means to be successful in obtaining food.

These underlying necessities of their existence were not required only occasionally but constantly; upon them the preservation of the species depended. The necessity for an internal pressure as low as possible—that is, as low as consistent with the general metabolism of the animal—and an ever-readiness for flight lead to the suppression of the primitive pubo-coccygei present in their earliest ancestors (cf. Hyrax), and explains the undeveloped state of their larynx, just as their constant vigilance and the necessity for an extensive field of vision determined the aperture of their pupil to become a horizontal slit so that they might view the whole horizon simultaneously. This suppression of the pubo-coccygei permitted an easy defæcation and allowed the act to take place without the interruption of their locomotion, defæcation occurring in them as well trotting as standing still, for the absence of these muscles permitted it to occur without straining—that is, without an increase of visceral pressure, to procure which the crouching attitude is so necessary in Carnivora and the Primates.

Yet the pressure within required for an adequate circulation and expiration is provided for by several devices. Thus, the pelvis of these animals, in relation to the abdomino-pelvic cavity, is very highly placed, being situated almost at its summit, and is very obliquely inclined, so that its outlet looks much more upwards than backwards. Their bodies are nearly always maintained with the long axis horizontal; they never crouch or sit, and if they rear they do so but rarely, and only momentarily. Thus there is not the same necessity for such a closure of the pelvis as occurs in Carnivora; for they avoid those postures of the body, for the maintenance of which a considerable increase of internal pressure is essential. Their abdominal viscera are supported by the well-developed abdominal wall musculature, which slopes downwards and forwards from the pelvis towards the diaphragm, upon the tonic contraction of both of which the internal pressure conditions depend. These musculatures control their respiration: inspiration being effected by the posterior recession of the diaphragm, and a corresponding displacement of the abdominal viscera and protrusion of the belly wall; whilst expiration is determined by the lessened contraction of the diaphragm and a replacement of the viscera by the abdominal wall (Keith). Thus the thoracic diaphragm and abdominal wall musculatures react against the weight of the viscera; and when the pressure within becomes of necessity higher than usual, e.g., during coughing, the pressure impulses which are transmitted upwards and backwards to the pelvis are prevented from escaping by the closing mechanism provided by the high development of the superficial perineal musculature.

The preservation of the Carnivora, on the other hand, depended on their devouring prey, and was only possible by successful stalking and slaughter. Stalking required cunning, and thus the higher psychical centres were stirred to greater activity; slaughter necessitated the use of the fore-limbs for striking purposes, and this in turn a fixation not only of the thorax but of the whole body. The necessity to hold the breath entailed by such fixation called the muscles constricting the glottis into greater prominence; the simultaneous necessity to convert the soft and supple abdomen into a comparatively rigid mass determined the further development of the pubo- and ilio-coccygei, the presence of which allowed a powerful and efficient vocalisation, and eventually permitted the assumption of the erect posture.

Can there be any doubt that the function of the caudo-pelvic muscles, which first definitely appeared in the Amphibia in association with the necessity for an increased visceral pressure, which evolved further during the Reptilian Era for the same end, and which in Carnivora have continued to evolve in association with the development of the

§ "In animals whose motions are chiefly those of running we find the ventricular bands (of the larynx) absent, or slightly developed. But in animals where the anterior extremities are used for striking, hugging, or climbing the vocal cords are strongly developed."—Valvular Action of Larynx, Journal of Anatomy and Physiology, vol. xvii., 1882-83, by Sir Lauder Brunton and Professor J. Theodore Cash.

‖ The loud, disturbing bark of the dog is a good example. In this case inspection shows how the impulse accompanying each bark is reflected against the perineal region—an observation for which I am indebted to Dr. James Collier.

fore-limb for striking purposes, and that of the larynx for powerful vocalisation, is really a pressure one, and that it reacts in association with the abdominal wall musculature and the thoracic diaphragm to this end? If this be so, the absence of the pubo- and ilio-coccygei in Ungulates is explained.

GEOLOGICAL RECORD AND CONCLUSION.

In support of such a conception of the evolution of the Ungulates is the remarkable richness of the geological record in the case of the ancestry of the horse. Not only is it known that the horse—like all the mammalia (Beddard)—evolved from small forms, but that it evolved from animals with five digits, and that these in the course of evolution have been suppressed. That this suppression has occurred as the result of change of habit is shown by the fact that in the early stages it was more advanced in the hind foot than in the fore, such as we can readily imagine to have been caused by the hind foot giving up grasping or clawing movements at an earlier period than the fore-foot. Thus in Eohippus the fore-foot had four digits, with a vestige of the first, whilst the hind foot had only three; it stood 11 inches in height at the shoulder and was more like a carnivorous animal than an ungulate (Lull). Owing to the increasing adaptation to speed—which like all changes was but slow—"after vast ages," the suppression of the extra digit of the fore-foot was effected, and from that time the retrogression in each has been the same. "Still," writes Lull, "it is curious to note that, among living horses, in instances of reversion to ancestral conditions, the fore-foot is more apt to exhibit well-developed atavistic toes, showing that in it the reminiscent tendencies are stronger." In connexion with this it is interesting to discover that in the Tapir, "the most ancient of existing forms referable to the Perissodactyla Order" (Beddard), the fore-foot has four digits, but the hind-foot only three. We have but the bones, and often but few of these, from which to gain an idea of the skeleton of past forms; but as the skeleton and the musculature—indeed the whole structure—go hand in hand, it is not difficult or unreasonable to suppose that changes in the soft parts were similarly affected.

The same examination and arguments may be applied to other orders of animals. In the case of the Rodents, to which Hyrax is so similar, we may suppose they escaped destruction by hiding, rather than fleeing, and to this end learnt to burrow. Such activity in them as in the Ungulates was not so necessary, perhaps explaining their small size; but it is significant to find that in those that are hunted, such as the rabbit and the hare, the pubo-coccygeus is only feebly developed or not to be found. In them, as in the Ungulates, the pelvic outlet is secured by the superficial sphincteric layer of muscle. Similarly, in the Guinea-pig the pubo-coccygeus is only present as a fine membranous-looking muscular sheet. Yet in others, which have taken to climbing, as the Squirrel, the pubo-coccygeus and ilio-coccygeus are almost as well developed as in Carnivora. So animal after animal can be instanced, showing the response of the pelvic-floor muscles to form an adequate closing apparatus for the pelvis, sufficient for the maintenance of the internal pressure conditions of the particular animal—conditions which vary from time to time and depend on many factors, all of which themselves depend on the habits and mode of life of that animal. Thus the caudo-pelvic muscles of pronograde mammals, like those of the non-mammalian vertebrates, exist for one end—namely, a pressure effect, for they form an integral part of the internal pressure-regulating mechanism; and thus, in a most beautiful way, is exhibited a principle, universal throughout the vertebrates and dominating their lives, a principle becoming ever more dominant as we ascend the series, and which, had we time to consider it, we should find had reached its climax in man.

It is now my pleasing duty to acknowledge my obligations. I have to thank the Museum Committee of this College for permission to work in the Research Laboratories here and for material; I am indebted to Professor Keith for much personal kindness, help, and encouragement with the work; also to Mr. Burne, especially for drawing my attention to the structural conditions in the viscera of aquatic mammals; to Mr. Beddard, F.R.S., Prosector to the Zoological Society, for material; and finally, Ladies and Gentlemen, I have to thank you for your kind attention.

LIST OF ANIMALS DISSECTED FOR LECTURE II.

Carnivora and Pronograde Primates.—Dog (*Canis familiaris*). Lynx (*Felis lynx*). Civet (*Viverra civetta*). Seal (*Phoca vitulina*). Monkeys (*Semnopethicus entellus* and *Macacus sp.*).

Rodents.—Porcupine, tree-climbing (*Erethizon dorsatum*); brush-tailed (*Atherura africana*). Rabbit (*Lepus cuniculus*). Guinea-pig (*Cavia porcellus*). Hare (*Lepus europaeus*). Squirrel (*Sciurus ludovicianus*). Coypu Rat (*Myopotamus coypus*).

Ungulates.—Horse (*Equus caballus*). Panolin Deer (*Cervus eldi*). Hyrax (*Procavia*).

Marsupialia.—Wallaby (*Macropus bennettii*).

Edentata.—Great Ant-eater (*Myrmecophaga jubata*).

Monotremes.—Ornithorhynchus (*Ornithorhynchus anatinus*). Echidna (*Tachyglossus aculeatus*).

TWO CASES OF POISONING BY COAL-GAS FROM A "GEYSER," ONE OF WHICH ENDED FATALLY WITH MENTAL SYMPTOMS.[1]

BY ARTHUR J. HALL, M.A., M.D. CANTAB., F.R.C.P. LOND.,

PHYSICIAN, SHEFFIELD ROYAL HOSPITAL; LECTURER ON PRACTICAL MEDICINE, UNIVERSITY OF SHEFFIELD.

ON August 28th, 1909, I was asked by Dr. K. Gordon, who was at that time acting as locum-tenens for a Sheffield medical man, to see with him a young woman presenting somewhat puzzling symptoms. The history was as follows.

The patient was a school teacher, aged 33 years. On the previous evening, about 9.30 P.M., Dr. Gordon had been hastily summoned and had found her lying unconscious in bed. The friends said that she had gone upstairs to have a hot bath and that soon after this they heard sounds as of someone groaning. The groans came from the bathroom, the door of which was locked. As they obtained no answer to their knocking and shouting, they burst open the door and found the patient lying unconscious in the bath with her head to one side, but not under water. They carried her to bed and sent for Dr. Gordon. On his arrival he found her deeply comatose, with stertorous breathing, limbs flaccid, no

[1] A paper read before the Northern Branch of the Medico-Psychological Society on April 19th, 1910.

cyanosis, no convulsions, and no pyrexia. Over the left lung râles were heard and high-pitched breath sounds. He was unable to satisfy himself as to the cause of the attack; the question of poisoning by carbon monoxide was considered, but nothing was found to indicate such a thing. The geyser in the bathroom was examined; it was properly turned off and had previously been regularly used for years without trouble. There was no smell of gas. The bad light in the bedroom at night made it difficult to see colour changes in the skin, but the face appeared rather pale than otherwise, and there were no means of examining the blood spectroscopically. She recovered complete consciousness at 7 A.M. next day. She remembered going dizzy after getting into the bath, then her sight failed and she remembered no more. There was a history that she had been getting anæmic lately, that 15 years ago she had a severe attack of chorea, and more recently a gathering in her left ear and an abscess that burst in the left side of the neck.

I saw the patient with Dr. Gordon later in the morning, and could then detect nothing definite the matter with her, except some fine crepitations over the upper left chest with impaired resonance and broncho-vesicular breathing. We ascertained from the landlady—for she was living in lodgings—that the patient had been out of sorts and overdone with her work, which had just begun again after the holidays, and that she was engaged to be married shortly. She was quite bright and well, and there seemed nothing upon which to base a definite diagnosis. Meanwhile, she was advised to stay away from work and have a complete rest.

Further developments of a very definite kind, however, soon came. On Sept. 6th, in the morning, I received an urgent message to go at once to the same address, and Dr. Gordon gave me the following history. It appeared that the man to whom our former patient was engaged had come over for the week-end to stay with his *fiancée*, and on this, the Monday, morning went to have a hot bath before leaving. As he seemed to be a long time in the bath they began to get anxious, and hearing no sounds they burst open the door. They found him lying unconscious in the bath; the bathroom smelt strongly of gas, and the geyser was turned on, but the light was out. On Dr. Gordon's arrival he found the man comatose, respiration had ceased entirely, and the pulse was almost imperceptible, but he was distinctly red instead of cyanosed. Realising that carbon monoxide poisoning was the cause, he took the necessary steps to deal with the case, and by dint of artificial respiration kept up for an hour, and hypodermic injections of strychnia and atropine the respirations returned and the pulse improved.

When I saw the patient shortly after, he was still comatose. The respirations were deep and slow, and the pulse was small and frequent. The lips were closed; the limbs were somewhat rigid. His colour was not strikingly red, but distinctly so, and in marked contrast to the usual cyanosis of asphyxia. Spectroscopic examination of the blood, which had a typical CO-hæmoglobin tint, showed the characteristic spectrum of carbon monoxide. He gradually regained consciousness and there appeared to be every prospect of his complete recovery.

Had this been the whole of the story it would hardly have called for comment or record, as similar results from defective geysers are not uncommon; but the sequel was unfortunately not so happy. On returning to consciousness the patient seemed quite dazed. This was naturally to be expected at first, but as time went on this dazed condition did not pass off, and although he had so far recovered by the next day as to be able to get up and come downstairs, his mental condition was found to be quite altered.

On Sept. 8th I was asked to see him again and found him sitting with his friends downstairs, apparently quite well, but on talking to him he was evidently confused. When asked the day of the week he hesitated for a long time, as though he were thinking about it and trying to remember, but he could not name it correctly. So also he had forgotten where he lived and named a place he had lived in years before; he did not know he was in Sheffield, but said in Manchester, where he had been previously. Unless spoken to he never said anything, but sat gazing in front of him. At night he was restless and tried to get out of bed. He was taken into the Royal Hospital under my care the same day, and a general examination showed no evidence of organic disease. He was kept in bed and his mental condition remained precisely the same as described above. On Sept. 9th he had some incontinence of urine during the night. He was not at all restless. On the 11th there was abdominal distension, and the incontinence of urine continued; the temperature also rose to 99° at night. On the 13th he received a letter which he appeared to be reading, but on being asked to read it aloud he could not do so, not even the address. When shown large print and asked to read it he frowned and appeared to wish to convey the idea that he could do so easily, but could not read more than the first word and then stopped, after which he went on staring vacantly at it without making any further advance, his eyebrows contracted, and a troubled look on his face.

This condition continued practically unchanged up to his death. The incontinence of both urine and fæces continued, and catheterisation had to be resorted to. The urine became alkaline and offensive, and later contained blood and pus. The temperature kept slightly raised, 99° to 101°. The pulse, which on admission was only 60, had reached 120 by the end of the first week, and remained about that rate up to death. On Sept. 15th the right knee-jerk was more marked than the left; toe extension was present on both sides; there was no clonus. On the 17th he was more drowsy, but slept badly at night. On the 21st he had occasional hiccough and involuntary twitching of the legs. His mental condition was more clear and he knew for the first time that he was in hospital. He died on Sept. 23rd, 17 days after the CO poisoning.

At the necropsy, made by Professor J. M. Beattie, a careful examination of the brain was made, but nothing was found abnormal to the naked eye except some slight cystic changes of the choroid plexuses. Unfortunately no microscopical examination was made.

This somewhat unusual sequela of poisoning by carbon-monoxide was complicated by some curious information afterwards obtained from the landlady, information which made it somewhat doubtful whether the mental symptoms were really due entirely to the poison. Thus, she said that when he was found in the bath there was no water in it and that he was sitting on the towel. As was stated above, the geyser gas tap was found turned on but not lighted, and the smell of gas was quite evident. The bathroom was very small, the window shut, and the escape flue of the geyser, which led through the wall to the outside, was, as the gas inspector found, practically occluded. The inspector thought it was quite possible that with this condition the gas after being lighted had been smothered out for lack of oxygen.

Naturally at the time, not knowing of the above facts, this seemed a reasonable explanation of the accident, but after the landlady's statement it seemed quite possible that the case was one of attempted suicide rather than accident. On the other hand, they assured us that prior to the occurrence he had seemed perfectly right and quite unlike his state afterwards.

The point, however, as to whether the deceased attempted suicide or not is somewhat doubtful. In a letter which Dr. Gordon kindly sent me he writes: "I saw B (the patient) when his *fiancée* became ill, several days before his second visit and mishap, and he struck me as a very sensible, level-headed man."

From the point of view of the psychologist this question seems to me a very important one in view of the after results in this case, but so far as sifting the evidence goes, it seems impossible to get further towards a solution of it. There is no doubt that mental symptoms do follow CO poisoning with considerable frequency and in great variety, both as to duration, severity, and type, even in persons previously healthy.

Dr. Alexander Scott of Glasgow recorded[2] a case in which the patient, after poisoning with gas from some ammonia works, remained semi-comatose for ten days, and on the fifteenth day became acutely maniacal for 24 hours, after which he relapsed into his previous condition for eight days longer. After this he began to improve, but his mental condition was completely altered, and except for occasional lucid intervals of a few minutes' duration, he remained continually listless and took no intelligent interest in his surroundings for more than three months after. I wrote to Dr. Scott as to the further history of this man, and he kindly furnished me with the following statement: "Shortly after the delivery of my lecture my patient was removed to an asylum, where he remained for three months and died from cerebral softening. Unfortunately a post-mortem examination was not allowed."

[2] Scott: THE LANCET, 1896, vol. i., p. 217.

Dr. Scott also quotes a case reported by Stockes[3] in which great prostration and mental weakness lasted for two months after poisoning. He likewise quotes a case privately communicated to him, in which the patient was maniacal for three days and quite insensible for eight days. He remained unable in any way to look after himself for two years, and even after that he was feeble-minded and could not undertake any responsible duties. Leppmann[4] has described a case of severe hysteria following poisoning, also one of cerebral hæmorrhage. Levin[5] reports a case in which persistent tachycardia, headache, and restlessness followed CO poisoning, although during the time the patient was in the poisoned atmosphere no severe toxic effects occurred. He questions whether the symptoms were due to the poisoning or to a pre-existing hysteria.

Izard[6] in a thesis for the doctorate gives a full account of the various nervous sequelæ of CO poisoning under the following heads: Motor: Hemiplegia, paraplegia, partial paralysis. Sensory: Subjective, pain; objective, hyperæsthesia, anæsthesia. Sensorial: Affections of sight and hearing, multiple sclerosis, hysteria, chorea, tetany. Intellect: Affections of memory, melancholia, mental confusion, chronic temporary mania, dementia, affections of speech.

Mott,[7] in a paper on carbon monoxide and nickel carbonyl poisoning, considers very fully the changes in the central nervous system produced by CO, and shows that, microscopically, very definite lesions of the brain can be demonstrated. The cortical vessels are dilated, but in the subcortical white matter the changes are more marked—viz., congestion, hæmorrhage, and the rupture of small vessels. Sometimes this rupture is into the brain substance, sometimes into the perivascular sheath. The capillary endothelium appears swollen and shows fatty changes. The most marked changes are seen in the white matter of the centrum ovale, especially in the occipital lobe.

The chief points of interest of my cases from the mental side seem to be: 1. Was this man's state of confusional insanity due to the action of CO alone on the cerebral tissue or was the mental condition beginning before the CO poisoning? 2. How does the CO act?

1. Mott[8] says: "In considering the effect of carbon monoxide poisoning being followed occasionally by mania, melancholia, confusion, and other mental symptoms, it must be remembered that many of the cases were suicidal, and therefore if not actually insane at the time probably possessed an insane and neuropathic temperament." That may be granted. But on the other hand, it is perfectly certain that some cases in which similar mental disturbances have followed CO poisoning were not cases of suicide, as, for example, that quoted above from Dr. Scott's paper, and therefore the power of the CO to produce these effects in some persons without their being insane at the time exists. Moreover, one does not (I speak here with much diffidence before those of far greater experience than myself on these subjects) find similar fatal mental symptoms in the average suicide who fails to carry out his purpose by some other means such as poison, injury, or drowning.

In my case, as we have seen, the question of suicide is somewhat complex. Whilst talking over this case with a well-known professor of jurisprudence the other day he said to me: "There is one golden rule to remember: Whenever an obscure death occurs in a person who is going to be married, it is *suicide*." In his opinion the rule should be applied in this case.

2. How does the CO act on the nervous system? There are two principal hypotheses: (*a*) That all the symptoms are produced by the anoxæmia due to the action of the CO on the oxyhæmoglobin of the red cells, with resulting deprivation of oxygen to the nervous tissue and vascular changes, hæmorrhages, thromboses, and degenerations; (*b*) Le Dosseur's theory[9] that the CO, having once saturated the red cells, becomes dissolved in the serum and attaches itself to the nerve cells and has a direct toxic effect on them. Which, if either, of these two views is correct remains to be proved.

A CASE OF

UNRUPTURED TUBAL PREGNANCY OF THIRTEEN MONTHS' DURATION; OPERATION AND RECOVERY.

BY JONAS MORRIS, M.R.C.S. ENG., L.R.C.P. LOND.,
ACTING SURGEON TO THE BRITISH HOSPITAL, BUENOS AIRES.

THIS case, which presents several interesting features, came under my observation on Oct. 12th, 1909. The notes of the case are as follows.

A married woman, aged 34 years, a Hungarian by birth, was admitted to the British Hospital, Buenos Aires, on Oct. 12th, 1909, complaining of a tumour in the abdomen, the cause of which was attributed by the patient to "a baby three months over time." From the previous history it appeared that the menses had always been regular. She had been married for 13 years and had had one child, a male, who was born in July, 1905, nine years after marriage. There had been no miscarriage. She had suffered for some years from a white discharge, which came on 15 days before each period. This condition persisted up to the first pregnancy and then disappeared.

The history of the present condition showed that on Sept. 17th, 1908, the menses ceased. Early in October morning sickness began and persisted up to February, 1909. In July there was a recurrence of the morning sickness at intervals during the whole month. In November the patient had a loss of blood per vaginam, passing a clot which she described as being like "a piece of lung." There was no history of passing any membrane. At this time her medical man, on being consulted, told the patient that she was not pregnant. In March "quickening" was first felt. The movements continued up to the month of June. About the same time (March) milk appeared in the breasts, continuing up to about the beginning of October, after which it disappeared. The swelling of the abdomen increased up to June, after which, according to what the patient states, it appeared to shrink. In February she consulted another medical man, who told her that she was pregnant. In June, about the time the patient was expecting her confinement to take place, she had a "show" of blood, together with bearing down pains. She called the midwife and had all preparations made for her confinement. During the pains she states that she felt the child "go down," and could feel what appeared to her to be the head above the pelvis on the left side.

On admission the patient was a well-nourished woman, with marked right internal strabismus. The circulatory and respiratory systems were normal; the breasts were flaccid, no secretion being present. The urine was acid, of specific gravity 1020; there was a deposit of mucus; albumin was present to the amount of 3 grammes per litre according to Esbach's albuminometer. On examination of the abdomen the lineæ albicantes were well marked. A tumour could be felt extending from the pelvis upwards to within 6 centimetres of the xiphisternum; it was pyriform in shape, the larger extremity being upwards and slightly to the right. In some parts the tumour presented a feeling of elasticity, whilst in others it presented distinct irregularities, hard and non-elastic. A well-marked irregularity existed on the left side on a level with the umbilicus. No thrill could be felt. In front, a little to the left of the middle line, a soft pyriform tumour could be felt extending about 7 centimetres above the symphysis pubis, slightly moveable from side to side, lying in front of the aforesaid tumour. This was presumably the uterus, as traction on the cervix uteri caused it to move. Per vaginam some whitish mucoid discharge was present. The os uteri was somewhat patulous and soft to the touch. There was a marked bulging in Douglas's pouch, which on bimanual examination gave a distinct sense of elasticity. Scarcely any movement in a vertical direction could be detected, as the part of the tumour in Douglas's pouch appeared to be fixed.

On Oct. 21st I performed laparotomy. The abdomen was opened in the middle line below the umbilicus. The tumour immediately presented itself at the opening, but owing to its large size and the number of adhesions present it was found impossible to remove it intact. In view of this the sac was incised and emptied of about 700 grammes of liquor

amnii mixed with meconium, giving the fluid a green colour. The incision into the sac having been enlarged, the fœtus was found lying with its back to the abdominal walls in position of complete flexion, the breech being upwards and to the right, the head downwards and to the left. Delivery was effected, breech first, through the incision. The cord, which was found completely thrombosed, was cut. The sac was next examined and found to be the dilated right Fallopian tube, unruptured. It was lying posterior to the uterus, having evidently fallen back in such a manner that its posterior surface became placed in apposition with the right postero-lateral surface of the uterus, to which it was densely adherent. On the posterior surface of the sac were several omental adhesions which had to be separated between ligatures. The adhesions with the

To illustrate a case of unruptured tubal pregnancy.

postero-lateral surface of the uterus were separated with some difficulty and consequent amount of oozing which, however, stopped on pressure. Finally, the adhesions in Douglas's pouch were separated, leaving the sac completely free, except for its connexion by a short pedicle with the right cornu of the uterus. A ligature having been passed round this the sac was removed. As there was some oozing consequent on the number of adhesions which had to be broken down, a long drainage-tube was passed into Douglas's pouch, and the abdominal wound was brought together by through-and-through sutures, except for about 4 centimetres at its inferior angle, where room was left for the tube. The operation occupied 45 minutes.

The patient stood the operation very well, the amount of shock being very little. She made an uneventful recovery and left the hospital on Dec. 1st, 1909. The last trace of albumin disappeared from the urine on Nov. 26th.

The fœtus was a fully developed male child (dead); the weight was 2650 grammes (about 5¾ pounds), and the length 49 centimetres. The nails were long and there was complete growth of hair on the head. No odour came from the specimen. Desquamation of cuticle was present on various parts of the body. A certain amount of lanugo and vernix caseosa was seen on the surface of the body. The sac, as already stated, was formed by the dilated right Fallopian tube, its walls being on an average 3-16ths of an inch in thickness. The placenta was situated on the posterior wall.

I refrain from making any comments on the case as the facilities for consulting the literature on the subject are not at my disposal, but I cannot help thinking that such cases must be of rare occurrence and of sufficient interest to merit publication. In conclusion, I wish to express my gratitude to my colleague, Dr. Welchli, for assisting me in taking the history of the case by acting as interpreter, as the patient spoke German only.

Buenos Aires.

INTRACRANIAL COMPLICATIONS OF MIDDLE-EAR DISEASE.[1]

BY A. J. HUTCHISON, M.A., M.B., C.M. GLASG.,
SURGEON TO THE BRIGHTON THROAT AND EAR HOSPITAL.

THE question is often asked, "What proportion of the general death-rate is due to middle-ear suppuration and its sequelæ?" Taking four series of consecutive post-mortem examinations in general hospitals, amounting together to 23,838 cases, it is found that 1 death in 198 resulted from middle-ear suppuration—i.e., practically 0·5 per cent. A second question often asked is, "What percentage of patients with middle-ear suppuration die of that disease or its results?" Several authors have attempted to find the answer, but they all admit that their investigations have been very unsatisfactory, owing to the elusiveness of the material. One author[2] states the death-rate at 2½ per cent.

The principal complications of middle-ear suppuration are: (1) meningitis; (2) intracranial abscess; and (3) sinus phlebitis and pyæmia. Of 973 cases reported by several writers, there were meningitis in 362 cases, abscess in 355, and sinus phlebitis in 256.

Four cases of intracranial complication of middle-ear suppuration have come under my care. Of these two were cases of temporo-sphenoidal abscess, the one not recognised during life, the other correctly diagnosed, opened, and drained, but ending fatally from septic encephalitis; the third was a case of extra-dural abscess, and the fourth one of lateral sinus thrombosis, the last two making complete recoveries. The cases were as follows, viz.:—

CASE 1.—The patient, aged 26 years, came to the Brighton Throat and Ear Hospital in November, 1903, complaining of pain in and discharge from the left ear, with some giddiness and headache. The symptoms were said to be of only a few weeks' duration. He refused operation then, but at the end of February, 1904, came into hospital, the discharge from the ear still continuing, but all the other symptoms being much improved. Some granulation tissue was curetted away from the perforation in the postero-superior segment of the membrane and from the adjacent bone. After-treatment consisted in cleansing the ear with peroxide of hydrogen, syringing, and light packing with antiseptic gauze. Earache, headache, and giddiness disappeared; the discharge gradually decreased, and the patient was discharged from the ward (to become an out-patient) on March 12th, 1904. During the night of March 13th or early morning of the 14th he suddenly became very ill and died in about 20 minutes.

At the post-mortem examination the roof of the antrum and tympanum was found to be carious and the dura mater there was discoloured. On the surface of the temporo-sphenoidal lobe in a position corresponding to this discoloured piece of dura mater was a soft yellow area of about the size of a shilling, and this led up to an abscess cavity of about the size of a walnut, with almost black walls, and full of greenish stinking pus. This cavity communicated with the descending horn of the lateral ventricle; and purulent fluid was found in the lateral, the third, and the fourth ventricles. The cerebellum, the pons, and the medulla were normal, and there was neither meningitis nor sinus thrombosis. The sudden death was probably caused by the rupture of the abscess into the lateral ventricle. During the patient's stay in hospital his condition appeared so satisfactory that no special examination was made of his nervous system.

CASE 2.—The patient, a girl aged 22 years, gave a history of suppuration in both ears since some illness in childhood. There were slight discharge from both ears and intermittent headache and earache, these being sometimes on the right, at other times on the left, side. The patient was very deaf and rather dull and stupid, but was able to earn a living. She was under treatment as an out-patient for some nine months. Then, as the earache in the right ear and the headache grew more persistent a radical mastoid operation was performed on that side. A small area of carious bone was removed from the roof of the antrum, but the exposed dura

[1] A paper read before the Brighton and Sussex Medico-Chirurgical Society on May 5th.

[2] Barker: University College Hospital, 1877–1888.

mater did not appear to be diseased. The antro-tympanic cavity was full of cholesteatoma. At first the patient made satisfactory progress. On the eighth day after the operation she complained of headache and vomited soon after her dinner, then was quite bright and comfortable. On the ninth day she again complained of headache and in the afternoon looked ill. Her pulse was found to be 60 per minute about 4 o'clock, at 5 o'clock it was only 50 per minute, and the patient was growing drowsy. About 8 P.M. the patient was very drowsy, the knee-jerks were increased, ankle clonus was present, the pulse was 50, and the right pupil was dilated and fixed, while the left was normal; there was no optic neuritis. The mastoid wound was then re-opened, more bone removed from the floor of the middle fossa, and a large abscess was found in the temporo-sphenoidal lobe. On opening the abscess a considerable quantity (unfortunately not measured) of stinking greenish fluid gushed out. A large drainage-tube was introduced. The right pupil immediately came down to normal size and next morning ankle clonus, &c., had disappeared. Two days later left hemiplegia, beginning at the face and extending to the foot, developed during the night. In order to relieve intracranial pressure bone was removed from the side of the skull over the temporo-sphenoidal region. This had no beneficial effect on the hemiplegia. The brain began to herniate through both this wound and that on the floor of the middle fossa and continued to do so for several days. The patient gradually sank and died on the twelfth day after the opening of the cerebral abscess.

CASE 3.—The patient, aged 24 years, was carried into the Brighton Throat and Ear Hospital in a comatose condition on March 18th, 1906. Practically no history could be obtained except that he had suffered from otorrhœa for a long time, that he had complained of earache and headache for three or four days, that he looked ill on March 17th, and was beginning to grow drowsy on the morning of the 18th. When brought to hospital he put his tongue out when ordered in a loud voice to do so, and answered "All right now" to questions. The head was slightly retracted and the neck stiff. Both ears were suppurating; in the right membrana tympani there was a large clean-cut perforation without any granulation tissue, while the fundus of the left ear was blocked with granulation tissue. A careful examination of the eyes, of the reflexes, &c., gave no information as to the probable site of the intracranial mischief; but as the fundus of the left ear was blocked with granulations, whereas the right ear was free, it was decided to open the left mastoid. The cortex was very dense. On opening the left mastoid antrum a drop of pus was found oozing slowly through the tegmen. The tegmen was therefore removed freely, and thus a large extradural abscess was opened. A large drainage-tube was introduced and the wound dressed. On removing the dressings next day pus was found between the dura mater and the squamous portion of the temporal bone. A disc of bone was accordingly removed in order to ensure free drainage. The patient made a slow but satisfactory recovery. When he was last seen (several months after leaving the hospital) the operation wound was quite healed, the ear dry, and the patient's health good.

CASE 4.—The patient, aged 48 years, had an attack of acute left middle-ear inflammation which came on during a bad cold in the head in the last week of November, 1909. Severe pain in the ear lasted a night, but was much relieved when the membrane ruptured and discharge commenced. As the pain, though less severe, still continued, the patient applied several very hot poultices over the ear and mastoid region, making the skin very red over these parts and even raising some blisters, thus blurring the clinical picture. On Dec. 3rd the following conditions were found—viz.: tenderness and slight swelling over the mastoid process; redness and slight bulging of the membrana tympani, in the postero-superior segment of which there was a small perforation; very little discharge; temperature 103·4° F. The patient was removed to a nursing home and a "Schwartze" operation performed. The bone of the mastoid process was soft and red, and contained here and there little pockets of pus, and pus was found in the antrum. The patient made fairly satisfactory progress for a week, but on the seventh day after operation she complained of pain in the left temple and to a less degree over the whole of the left side of the head, and of a tender swelling behind the angle of the jaw on the same side, and the temperature rose to 102°. By the evening the temperature had fallen to 99°, but the patient remained in a restless, irritable condition. On the tenth day the temperature rose to 104° and two rigors occurred. Examination of the heart, lungs, eyes, nerve reflexes, &c., revealed nothing abnormal. On the same evening the mastoid wound was reopened and the bone removed back to the lateral sinus. This was found to be full of thrombus which was just beginning to break down (a pure culture of streptococcus pyogenes was grown from this, and a vaccine prepared, of which four injections were subsequently given to the patient). The internal jugular vein was divided between ligatures, the lateral sinus incised, and the clot turned out. Free hæmorrhage occurred from the occipital end of the sinus; this was controlled by plugging. Normal saline solution was then syringed up the jugular vein, whereupon hæmorrhage began at the anterior end of the opened sinus. This was plugged and the ligature round the vein tied. The whole wound was then painted with tincture of iodine—a proceeding which was repeated nearly every day till healing was practically complete. The patient made an uneventful recovery, and is now in good health.

Brighton.

THE SPECIFICITY OF CANCER AND THE GENERAL PRINCIPLES OF ITS TREATMENT AND PROPHYLAXIS.[1]

BY ALEXANDER THEODORE BRAND, M.D., C.M. ABERD., V.D.,

EX-PRESIDENT, EAST YORKS AND NORTH LINCOLN BRANCH, BRITISH MEDICAL ASSOCIATION; FELLOW OF THE ROYAL SOCIETY OF MEDICINE.

THE treatment of disease is at all times beset with difficulty even when the cause is well known, and this difficulty is greatly enhanced in the case of maladies whose cause is still undetermined. In the latter class treatment can be only empiric. The cause of cancer has not, so far, been proved to demonstration, and unfortunately no remedy of any kind, even empiric, has been discovered; but though the cause has not yet been demonstrated by the production of the originating agent (and such is not remarkable since we are merely on the threshold of the knowledge of the causation of specific disease), still it is logically deducible from the well-known facts relating to the disease.

No disease more plainly bears upon itself the impress of specificity than cancer; indeed, this is one of its chief characteristics. Its constant primary local origin in practically any situation; its invariable extension by auto-infection, evidenced by its widespread dissemination by metastasis; its constant relation to a "condition precedent";[1] the innumerable so-called "coincidences" which clearly point to what would, in any other diseased condition, be considered infection; and the countless successful inoculations which have been made, all testify to its true specific nature—i.e., to its being as typically infective a process as syphilis or tuberculosis.

Although analogy is quite incapable of proving anything, being merely a "resemblance in relations," yet even analogy is not wanting, for cancer is strikingly analogous to such parasitic diseases as syphilis, tuberculosis, and pyæmia, in spite of the fact that it possesses one peculiar idiosyncrasy of its own, inasmuch as its metastases are formed by proliferation of the transported cells of the primary focus. In all other similar diseases the infective agent is transported free, while in cancer it is conveyed encapsuled in a tissue cell. This is only another example of the extraordinary variety of parasites and their ways.

Strange to say, some non-believers in its exogenesis openly assert that cancer is a parasitic disease, but they allege that it is the cancer cell itself which is the parasite. They do not appear to be able to appreciate the obvious logical *sequitur* that, since no somatic cell can, *per se*, be a pathogenic parasite, there must of necessity be an intracellular influence

[1] The "condition precedent" is a term introduced to indicate that state of vulnerability which must exist before an individual can be successfully attacked by the cancer parasite. It is induced by degeneration of tissue from any cause, more especially from obsolescence of organs, senescence, and senility, chronic disease, continued irritation, traumatism, and by congenital susceptibility.—A. T. B.

which endues it with its malign parasitic power. In other words, there must be an intracellular parasite, and all parasites are extrinsic.

Why the extrinsic origin of cancer is not universally accepted is to me incomprehensible in the face of evident facts; but the sooner it becomes generally received the sooner is the search for the causative agent likely to be crowned with success, and the stigma of its unsuccessful treatment to be removed from the practice of medicine. The concentration of research, based upon the logical hypothesis of exogenesis, must be more likely to be successful than the misdirected efforts of those who spend time and cerebral energy, not to speak of the great waste of money, in endeavouring to prove that a specific disease can possibly have an intrinsic origin, efforts which amount simply to beating the air.

It is generally admitted that all specific diseases, *except cancer*, arise by exogenesis—i.e., by infection from without—and that there is a known or suspected infective agent or parasite in each case which, so far as our present knowledge goes, is a micro-organism, either a microphyte or a protozoon, and that these diseases are communicated directly from individual to individual, or indirectly by inanimate objects, or through an intermediate host. With regard to cancer, I am convinced of its origin also by exogenesis, and that the infective agent resides in the invaded cells, although it has hitherto escaped detection.

I do not propose here to discuss the interesting problem why the hypothetical intracellular parasite of cancer has not been discovered, but I would remind you that the *Treponema pallidum*, responsible for syphilis, has only very recently been isolated, and that the parasite of small-pox and its bovine modification vaccinia (as well as that of many other specific diseases) still remains *perdu*.

That the infective agent of cancer resides in the invaded cell appears to me to be indisputable, since a single cell from a cancerous tumour is capable of reproducing the disease in another host, as has been proved by very many successful experiments, and an infected cell in the same host is capable of establishing a fresh focus of disease in another situation, as is evidenced by the formation of metastases, and by the reappearance of the disease in, or near, a surgical cicatrix from cells left behind, or introduced into the wound by the surgeon's knife, which has set them free from the originating growth.

Further evidence of the existence of an intracellular malignant agent, or parasite, is derived from the fact that the parenchyma cells of a carcinoma have been observed by Ehrlich and Apolant to impart a malignant stimulus to the surrounding connective tissue cells, so giving rise to a true sarcoma. From this evidence it may also be deduced that one and the same species of parasite is sufficient to originate any and every variety of malignant neoplasm, such variety being determined by the nature of the tissue attacked, and limited only by the anatomical diversity of the tissues themselves. Hence the urgent necessity which exists for the detection of the elusive pathogenic principle, both in the invaded cells and in the lymph and blood.

The exact date of attack in cancer cannot be determined, for, unfortunately, there is no known initial or prodromal symptomatology, and the interval between invasion and extension by auto-infective dissemination is consequently unknown, but it is believed to vary with the situation and tissue of the primary focus and that it may be very short. It is obvious that if the date of infection could be known at the time, and if the site were accessible, immediate excision or other destruction of the invaded part would be the ideal method of treatment, for such might be confidently expected to be absolutely successful, just as syphilis can be successfully averted by the immediate destruction of its causative parasite at the site of inoculation. Such data, however, with regard to cancer, in our present state of knowledge, are available only in the case of experimental or deliberate inoculation.

The bar to success in treatment is that it is never called for until the disease has given unequivocal evidence of its existence as a distinct tumour, and even where appearances might suggest an early and purely local invasion, widely disseminated extension, hopelessly beyond the surgeon's reach, has in all probability already occurred. It should, therefore, be a surgical axiom that if any inaccessible foci—e.g., infected lymphatic glands—are known or suspected to exist, as metastases of an accessible primary neoplasm, operation with a view to the removal of the latter is not only inadvisable but unjustifiable, for such a procedure would be utterly futile for the eradication of the disease. Not only, indeed, would operation in such circumstances be futile and unscientific, but it would probably be the actual cause of increase in the activity of the malignant process, by setting free, and scattering broadcast, infected cells hitherto confined, so that the last state of the patient would be worse than the first, and even life itself would be materially shortened. The presence of inaccessible foci does not, however, negative purely palliative operative procedures, such as the relief of œdema of the arm by lymphangioplasty, as devised by Sampson Handley, or the removal of necrosed and offensive tissues.

Unless distant extension is obvious free excision of the accessible diseased area, including infected lymphatic vessels and glands and adjacent structures—e.g., muscles, and especially fascia—may be attempted as *the first line of treatment* (*vis a fronte*), the surgeon bearing in mind that every single infected cell left behind or set free by his knife is a potential agent in causing a local and general recrudescence of the disease.

Although very exceptional cases have been recorded where tumours, undoubtedly malignant, have disappeared spontaneously, and although surgical removal of such tumours has apparently cured the disease in some cases, it is more than doubtful if any operative treatment of accessible malignant neoplasms is ever successful in the complete eradication of cancer; for by the time that a tumour has been discovered far-reaching infection has almost certainly already taken place. But for the incidence of fatal intercurrent disease, the malignant process must have inevitably reasserted itself sooner or later and eventually claimed its victim.

It is a marked characteristic of cancer, and one which it shares with syphilis, that it may remain quiescent for a time. Thus, a distant metastatic focus may remain dormant for an indefinite period, the victim being lulled into a false sense of security, to light up at last into fatal activity, while the final site of the disease may be so remote from the original focus as to mislead the surgeon as to its true nature.

As a concrete example of this I may quote a case of Sir Hector Cameron's. In 1894 he removed the left mamma from the patient of a medical friend. In 1903 this patient began to complain of so-called "rheumatic" pain in her left hip and thigh, which became so severe as to cause her to go to bed and have medical attendance. One day, on getting out of bed, the left femur spontaneously fractured. Her medical attendant could find no trace of cancer in any other part of her body, but the patient died from gradual exhaustion without any evidence of farther dissemination in lungs, liver, or bone. Here some infective particle, lymph conveyed, had metastatically resided in the medulla of the femur for nine years, making no sign, until at last waking into activity by quick growth gave rise to pressure, pain, destruction of bone, spontaneous fracture, and death from exhaustion. There can be no reasonable doubt but that if this patient had died during the interval from intercurrent disease—e.g., pneumonia—she would have been declared cured by operation of her original cancerous disease. Many other instances might be adduced where recurrence, subsequent to operation on the breast for malignant disease, has occurred in other situations—e.g., the vertebræ, brain, &c.—and after even longer periods of quiescence, but that just quoted will serve as an example.

This period of dormancy suggests that all infected cells are not equally active—i.e., that the hypothetical intracellular parasite is not always in the same state of development, some cells containing it in an intermediate form, which form remains quiescent until some unknown stimulus or time and circumstances favour its further evolution. Such a hypothesis would explain many otherwise inexplicable clinical facts relative to cancer.

It is evident, therefore, that want of success after surgical treatment must be attributed either to incomplete removal or to the occurrence of distant dissemination prior to operation.

Unsatisfactory as surgical treatment is in cases of accessible primary disease, there can be no hope from the surgeon where the neoplasm is inaccessible from the first or where it has shown itself to have become so after operation.

Dark indeed must the prospect appear to the man who believes cancer to be a constitutional disease with local manifestations and having an intrinsic origin, for even the surgeon can do nothing for its removal. After all, the surgeon can only be expected to deal with what he can see, and temporarily stave off impending death threatened by mechanical causes; he cannot reach the cause. Cancer is practically ineradicable by surgical means alone, for the reason already stated. If cancer is ever to be successfully treated, the cause itself must be attacked, and this can be done only by specific means. This constitutes *the second line of treatment (vis a tergo)*.

The surgeon confronted with a fully developed Hunterian ulcer is powerless to avert constitutional dissemination by the knife—indeed, it has already occurred. In like manner he cannot expect to eradicate cancer which has already become constitutional by local excision of its visible manifestation. The physician, on the other hand, in the case of syphilis, can view the local indication of the disease with equanimity, for he knows that he is able to combat constitutional disease successfully by proved specific remedies.

Cancer being as truly specific a disease as syphilis, and since the latter yields to internal specific treatment, it is reasonable to assume that the former will likewise be amenable to the same. In such treatment appears to lie the only hope of the victim of cancer, and well will it be for him when it has been established that this disease is due to an extrinsic cause, for recovery may then be hopefully looked for from appropriate remedies. Should the infective agent prove to be a protozoon, as is the case in syphilis, malaria, &c., and my belief is that the probability is in favour of such a parasite, then a parasiticide is indicated, similar in lethal action to those found effectual in these diseases. Among the methods of exhibiting such parasiticide kataphoresis of accessible neoplasms would doubtless commend itself.

The parasiticide specific for cancer must be sought for by experiment both on man and the lower animals; and I should imagine that investigators would find no more willing, nay zealous, coöperators than the human subjects of cancer themselves.

On the other hand, should the causal agent be found to be a bacterium, success may follow the exhibition of a cancer vaccine, prepared after the methods of Wright; or of an anti-cancerous serum. Until such serum can be procured from an individual cured of, or rendered immune to, the disease, the effect of auto-serum might be tried. This may contain a self-generated antitoxin; or, if it contains the toxin itself, its injection in small amount may act as a vaccine and stimulate the leucocytes to increased phagocytic activity.

From the foregoing considerations I would submit that the successful treatment of cancer will consist in the removal by surgical means of accessible tumours, more especially those threatening life from mechanical causes, combined with the internal administration of specific remedies, the latter being relied upon to check the further spread of disease and neutralise that already existing, by destroying the causal parasite; while inoperable disease, whether accessible or inaccessible from the first, can only be treated by specific remedies and such non-operative mechanical means as fulguration, X rays, radium emanations, kataphoresis, &c.

No less important, or even more important, than the curative treatment of cancer is its prophylaxis. It is a truism that "prevention is better than cure," although this naturally is not the dominant sentiment of the sufferer from the disease.

Everything that tends to the encouragement of the "condition precedent" should be avoided. We cannot, indeed, stay the flight of time, that *edax rerum* which brings in its wake senescence, senility, and the obsolescence of organs, which play so important a part in the incidence of cancer, but these may be greatly mitigated by a strict observance of all the well-known laws of health.

Cremation of the cancerous cadaver is imperative, since such would remove a very obvious risk of perpetuation of the cause of the disease when earth burial is resorted to—e.g., by the action of earthworms, which convey soil from a depth of 6 to 8 feet to the surface, and by the contamination, by percolation, of the sources of water-supply. All dressings of cancerous wounds, all discharges and dejecta from cancerous patients should be destroyed, preferably by fire. There should be thorough disinfection of all rooms and houses inhabited by those suffering from, or who have died from, cancer. Intimate personal contact with the diseased should be avoided as far as possible. Personal cleanliness should be scrupulously observed, especially in the washing of the hands before eating, and in the preparation of food. There should be perfect sterilisation of all water and food partaken of, especially when the latter is eaten in an uncooked condition; and the contamination of any food by the lower animals, or by flies, should be prevented.

If there is any truth in the allegation that the earthworm is an intermediate host, and that the soil is one *habitat* (water being another) of the parasite, the mere idea of eating raw vegetables, however well scrubbed and apparently clean, becomes repulsive, and is calculated to induce one to ponder over the desirability or otherwise of total abstinence from all uncooked fruits and vegetables which lie on or in the surface of the ground.

Mr. J. Bland-Sutton, in his recent work "Cancer Clinically Considered," says:—

> The frequency with which cancer attacks the large intestine is in favour of those who believe that cancer is due to a micro-parasite, probably something which is taken in with uncooked food or with water. Indeed, I feel so strongly on this matter that for many years I have avoided eating all sorts of uncooked vegetables. Much as I enjoy salad with my chicken, or my cheese, I do not touch it. However clean your celery may appear to be, if you pull aside the stalks immediately round the centre, which is about the only part worth eating, you will see that there remains some dirt which has not been washed away. One feels deeply thankful that most of the food eaten by mankind is cooked. Partially cooked or "underdone" meat carries penalties in the way of entozoa, and Metchnikoff says that "entozoa may serve as gates of entry for the hypothetical parasites of carcinoma." Food and water are essential to life, and it is undeniable that they are the frequent purveyors of disease, and that minute animal parasites are our daily messmates and table companions, though their presence is sublimely ignored by us. In Behla's opinion the probable vehicle of infection in cases of cancer occurring in Luckau in Germany was the uncooked vegetables.

Finally, notification of all cases of cancer should be enforced.

Driffield.

ON THE DEMONSTRATION AND STUDY OF SPORES IN THE SCHIZOMYCETES.

BY A. F. STANLEY KENT,

PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF BRISTOL.

THE demonstration of spores within the cell body of the schizomycetes has been attempted in different ways by different workers. At the present time, however, and even by modern methods, the process is tedious and uncertain, and, as is often the case with methods which do not depend upon accurately known chemical and physical processes, the preparation of satisfactory specimens calls for an excessive expenditure of time and care. Moreover, some of the methods which have been proposed result in a considerable amount of damage being done to the rest of the cell—a damage which may seriously impair the usefulness of the preparations, whilst investigators working upon spore formation find the prolonged methods necessary a great drawback.

Bearing these facts in mind, and happening to be working on the subject some few years ago, I considered the various processes used and the explanations given of their supposed rôle, when it occurred to me that the old idea of there being an envelope, or film, of a fatty nature in the neighbourhood of the spore, shutting it off from evaporation and from contact with aqueous solutions, whilst providing some explanation of the difficulty of decolourising already stained spores, might also give some indication of a method for enabling the stain to penetrate more easily. My experiments were often interrupted, but the indications given above being followed, a method was ultimately elaborated which enabled the more easily stainable spores to be coloured readily, whilst in the case of those which usually are coloured only with difficulty, the process is rendered easier.

The method at first consisted in the solution of the staining agent in a fatty solvent, and some success was obtained in this way, but soon another procedure was adopted and a different principle employed. The peculiarity of the method consisted in the employment of an alkali for

the purpose of rendering the resisting envelope of the spore permeable and readily penetrated by the staining solution. The desired result was found to be actually brought about by the alkali employed, and the resulting preparations showed the spores sharply stained, whilst the cell body was uninjured and might readily be tinged with a counter stain if necessary.

Briefly, then, the process consists in preparing a film in the usual manner and fixing it by heat or by other means. Solution of sodium hydrate is then flowed over the film and allowed to act for some seconds, after which the still wet (and alkaline) film is flooded with carbol-fuchsin solution and heated as usual. This heating, which adds considerably to the intensity of the staining, need not be at all prolonged, a few minutes being amply sufficient. It will be found that a precipitate is produced by the soda solution in the carbol-fuchsin stain, but this may be neglected, as it will to some extent disappear as the temperature rises, and in any case does not appear to damage the preparation.

The ordinary 25 per cent. hydrochloric acid is next flowed over the film and allowed to act for a second or two, then washed thoroughly off and the film flooded with 1 per cent. aqueous solution of methylene blue, which may be slightly heated if an intense stain is required. Thereafter nothing remains but to wash, dry and mount as usual.

This method has given good results in my hands and has been used in some research work carried out in the University of Bristol by Mr. A. E. Lechmere, who tells me that he has found it of service.

The exact strength of the soda solution which gives the best and most constant results is being ascertained, but it has been found possible to vary the strength within wide limits without spoiling the result.

Bristol.

A CASE OF CEPHALIC TETANUS (KOPF-TETANUS OF ROSE).

BY C. V. KEBBELL, M.R.C.S. ENG., L.R.C.P. LOND.,
HOUSE PHYSICIAN TO THE ROYAL BERKSHIRE HOSPITAL, READING.

THE patient, a boy 5 years old, was admitted to the Royal Berkshire Hospital under the care of Mr. W. J. Foster, assistant surgeon to the hospital, on Sept. 22nd, 1909, as the result of an injury occasioned by a fall from a wagon. A large flap of the scalp had been torn from the skull, exposing a portion of bare bone about one square inch in extent, situated over the parietal region of the right side in the neighbourhood of the parietal eminence. The whole area was covered with mud, which was ingrained into the tissues. Apart from this there was no evidence, on admission, of any cerebral disturbances or fractured bone. On the 29th it was noted that the child's condition was satisfactory and the wound was granulating up. On the following day, however (the 30th), slight facial paralysis became evident on the right side. Four days later this paresis was more marked, and slight head retraction with rigidity of the arms and legs was noticed. The child lay quietly in bed but resisted movement of his limbs. The possibility of septic infection of the meninges or a cerebral abscess was discussed, and it was decided to trephine.

The operation was performed by Mr. Foster, and an area of bone was removed at a point three-quarters of an inch above and behind the right external auditory meatus. The meninges bulged and pulsation was slight. No exudation was found on incising the dura mater, and a grooved director passed into the cerebral tissue and downwards towards the base of the brain located no pus. On the day following the operation (Oct. 5th) three spasmodic attacks occurred, during which the patient was quite conscious. There was also now some rigidity of the abdominal muscles between these attacks, and tetanus was diagnosed. Ten cubic centimetres of the antitetanic serum were injected, and the child was transferred to the isolation block.

I saw the patient on Oct. 7th. He was quite intelligent and took interest in his new surroundings. There was marked right-sided paralysis of the face. The masseter on both sides was very tense, and the interval between the upper and the lower teeth was just sufficient to admit the handle of an ordinary scalpel. The pupils were equal and rather dilated. Respiratory movements were embarrassed and "stuffy." The abdominal muscles were very rigid, the recti presenting a board-like resistance; the arms could be freely moved, but movement of the legs, which were kept flexed, was resisted. The knee-jerks could not be satisfactorily obtained, and there was no Babinski's sign. In the evening of the same day I was called up to find a spasmodic attack in full effect. The body was arched (opisthotonos), the abdominal muscles were tightly stretched, the face and lips were blue, and the pupils were widely dilated. The jaws were firmly clenched, and the child was conscious and evidently terrified at his condition. As it was urgently necessary to relax the spasm I administered chloroform. The patient objected to the smell of the anæsthetic, and the spasm for a few seconds increased in intensity, relaxing, however, again after a short interval. The abdominal muscles became flaccid, the colour improved, and the child slept for one hour afterwards. One minim of the injectio morphinæ hypodermica was given subcutaneously. Towards early morning of the next day (Oct. 8th) it was again necessary to induce anæsthesia, and several spasmodic attacks occurred during the day, making the patient very exhausted. He sweated profusely after each one, and the pulse showed a tendency to intermit. Brandy (half a teaspoonful four-hourly) was ordered, and a mixture consisting of potassii bromidi gr. v., chloral hydratis gr. ii., aquam menthæ piperitæ ad ℥ii. every four hours was prescribed. Ten cubic centimetres of the serum were injected in the evening. This occasioned a spasm and so was completed under chloroform. On Oct. 9th eight spasms were noted, three severe enough to call for anæsthesia. The effect of the inhalation of amyl nitrite was tried, but without much success. Oxygen was of use in improving the patient's colour, when the intensity of an attack lessened. The antitoxin was again given on this day. The usual procedures of darkening the room and absolute quiet were enforced, but although some of the attacks could be attributed to external stimulus, others occurred without any evident ascertainable cause. On the 10th and 11th antitoxin was repeated, and four spasmodic attacks occurred on either day. It was necessary to give nutrient enemata for some days as it was now difficult to get the child to take nourishment, owing to a tendency of the pharyngeal muscles toward spasm when swallowing.

On Oct. 13th, eight days from the onset of the first spasmodic seizure and 14 from the day on which facial paralysis was first seen, I noted that the severity and frequency of the spasms were less, though at intervals a sudden jerking of the body with clenching of the jaw would occur. The condition of the right side of the face continued about the same. During the next week improvement continued, and there was only one severe spasmodic attack. The occasional clenching of the jaw was still present, but the mouth could be opened wider. The scalp wound was slowly granulating up. No alteration in the facial paresis could be seen. The child was bright and intelligent, and interested in his own improvement. Tinctura strophanthi (1 minim) was added, and chloral was omitted from the mixture, as the pulse tended to be weak. The only complaint was of some pain in the throat on swallowing. After Oct. 22nd no twitchings or spasms occurred. Some rigidity of the jaw muscles continued till Jan. 1st, after which date the mouth could be fully opened. The muscles of the right side of the face did not regain their power, however, for a longer period still, and it was not until the middle of January, a little over three months from the onset of symptoms, that they could be said to be again quite normal. The child has been seen as an out-patient quite recently, and was in excellent health.

The interesting point in the above case is the association of facial paralysis with tetanus. This condition is described by Professor Osler under the name of "cephalic tetanus or Kopf-tetanus of Rose." This, he states, "originates usually from a wound on one side of the head, and is characterised by stiffness of the muscles of the jaw, and paralysis of the facial muscles on the same side as the wound, with difficulty in swallowing." All these points were displayed in the above case. Rose and Carless state that the paralysis is due to an ascending neuritis of the facial nerve which becomes compressed in the aqueduct of Fallopius. The mortality in the acute forms is given as four recoveries out of 45 cases. In the chronic forms eight out of 32 succumbed. The condition is uncommon. Osler states that the use of the antitetanic serum

is disappointing in man. Altogether five injections of 10 cubic centimetres were given in this case. Improvement appeared to follow the fifth injection, but it is difficult to say whether it was due to the beneficial action of the serum or to a natural tendency toward recovery.

The origin of the paralysis of the facial muscles may be suggested as due to other causes apart from tetanus. An isolated facial palsy, due to involvement of the cerebral cortex or internal nucleus, as a result of injury is uncommon. There is usually hemiplegia as well. Damage to the nucleus of the seventh nerve from hæmorrhage is likewise unusual. There were no signs of concussion or affection of other nerves to suggest a fracture of the base of the skull. A very localised patch of meningitis involving the seventh nerve, or hæmorrhage, affecting the face centre only from contre-coup, might be possibilities. There was no evidence of any bruising or damage at the level of the stylo-mastoid foramen to occasion an injury of the nerve there. There were no signs of ear disease, or involvement of the eighth nerve, and paralysis of the face of this duration due to cold is not common, so far as I have noted, in children. After considering all the above points, I think the diagnosis was correct, and that this was undoubtedly an unusual form of infection with the tetanus bacilli—cephalic tetanus.

My thanks are due to Mr. Foster, who very kindly gave me permission to publish the particulars of this case.

The Pancreatic (Cammidge) Reaction.

A MEETING of this section was held on May 24th, Dr. J. MITCHELL BRUCE being in the chair.

Dr. P. J. CAMMIDGE read a paper entitled "A Consideration of the Results of the Pancreatic (Cammidge) Reaction in 1475 Cases." The results of the analysis of over 1500 specimens of urine from 1475 cases were considered, particularly with reference to the so-called pancreatic reaction. They were divided into nine groups, according to the pathological findings and clinical condition:—(1) Acute or subacute pancreatitis, 17; (2) chronic pancreatitis, 859; (3) pancreatic calculi, 4; (4) pancreatic cysts, 4; (5) pancreatic infantilism, 1; (6) cancer of the pancreas, 73; (7) miscellaneous, 467; (8) normal, 50; (9) cases re-examined after operation, 55. The conclusion arrived at was that, while the "pancreatic" reaction in the urine was not pathognomonic, its presence was strongly suggestive of active degenerative changes in the pancreas, and when taken in conjunction with the history, symptoms, and an analysis of the fæces, the findings are of very considerable clinical value. Clinical experience and the results of experiments point to the reaction being due to the destruction of substances with a glyco-nucleo-proteid content, and, since the pancreas contains nearly five times as much pentose as any other organ of the body, calculated as percentage of the dry weight, and it was more loosely combined than the corresponding sugar in other tissues, the reaction was obtained with much greater frequency, and more constantly in lesions involving degenerative changes of that organ than in others. The affections that were likely to give rise to a positive reaction were usually so readily differentiated from pancreatic disease clinically, and by an examination of the fæces, that there was little or no risk of confusion. No reaction was obtained in most affections in which the pancreas was not involved, also in quiescent cirrhosis of the gland, some cases of pancreatic calculi and cysts, and in 67 per cent. of cases of cancer of the pancreas, since in those there was no active degeneration of the gland substance to set free the glyco-nucleo-proteid content of the cells, unless there was also a secondary inflammatory change due to pressure effects or obstruction of the duct. In conclusion, Dr. Cammidge said that the published experience of many observers, both clinical and experimental, tended to confirm those conclusions and to show the clinical value of the test and its dependence upon inflammatory and destructive lesions of the pancreas.

Dr. CAMMIDGE also read a paper on the Diagnostic Value of an Analysis of the Fæces in Disease of the Pancreas.—In the ensuing discussion Dr. MITCHELL BRUCE, Dr. H. D. ROLLESTON, and Dr. A. F. HERTZ took part, and Dr. CAMMIDGE replied.

MEDICAL SOCIETY OF LONDON.

Annual Oration and Conversazione.

A MEETING of this society was held on May 23rd, Dr. SAMUEL WEST, the President, being in the chair.

The annual oration was delivered by Mr. W. H. BATTLE, who took as his subject Internal (Intraperitoneal) Injuries. He said that if it were possible to ascertain the exact part of the body struck by the force which caused the injury, then one could make an approximate guess as to the organ ruptured, for it was generally lying beneath, and incision over that area gave direct access to the damaged structure. In all cases it was advisable to follow a certain routine in the examination of the patient. Ascertain when the last meal was taken, when the bladder was emptied, and if the patient was in good health before the accident. Inquire as to the position and extent of pain, and then examine the abdomen carefully for dulness and see if that is fixed or shifting. They will then have found out if there is rigidity of the muscular wall, whether it is general or local, and would know the amount of tenderness, its position and extent. The state of the pulse and also the temperature must be noted. From the practical point of view, they need not consider those cases which were admitted with intense shock from which they never rallied, patients in whom there was evidently a gross lesion but one which it was beyond surgical skill to attempt to remedy. The others could be arranged in fairly typical groups as they presented themselves clinically. In the first of those there were shock, acute abdominal pain with great tenderness over the part struck, and board-like rigidity of the abdominal wall. All those symptoms were present, but they varied somewhat in their intensity; at one time shock was the main thing, at another time it was the pain, and so on. With those there should be present a certain amount of localised dulness on percussion. In the second group there was no evident shock, and perhaps the patient walked to the hospital or went home, congratulating himself that he has had a "narrow escape." He may have vomited soon after the accident which made him feel sick, but there were no marks of injury on the abdominal wall, or they were but slight. He had considerable local pain, and there was rigidity of muscle sometimes confined to the side of the abdomen which was struck. There was tenderness on pressure and perhaps localised dulness, but he felt that he would soon get over it. In a third group the symptoms were rather indefinite; there was a history of abdominal injury, probably of the kind which sometimes produces a rupture of the intestine, but the shock was trifling, there was no vomiting, local pain was slight or absent, there was little tenderness, no rigidity of muscle, whilst percussion gave no change in note. After a variable time there might be a rising pulse with that change in facial aspect which indicated to the experienced eye the presence of grave peritoneal inflammation. It might not be easy to say at what moment that commenced, but "a change had taken place." It might develop after an attack of vomiting. In some instances where there was a definite history of the kick of a horse it would be judicious to operate at once, as recommended by Mr. Bernard Pitts, without waiting for symptoms. Should the escape of intestinal contents be very restricted, possibly in consequence of the smallness of the perforation, the symptoms might be limited to occasional sickness, with uneasiness in the abdomen, gradual distension and general tenderness, caused by a slowly extending inflammation of the peritoneum which might become localised, and result in the formation of an abscess. It must be remembered that a general meteorism might follow an injury to the abdomen without any rupture of the intestine or internal organ. A rigid condition of the abdominal muscles was a very important sign; it practically always meant serious underlying damage. Cases in which it

was present might in rare instances recover, but it was a sign which should be regarded as of great value, and in most as an urgent indication for operation. Dulness on percussion had been ascribed to escape of intestinal contents; this might be so, but it was rare to find much feculent fluid present when the abdomen was opened soon after an injury, although blood might be found which had come from a rupture of the mesentery or a tear of the omentum. If there was a history of localised contusion, such as that produced by a kick, and in addition to dulness under the part struck there was also fluid in one or both flanks, the mesentery was torn, and the indications for operation were evident to repair the injury and to prevent further bleeding, which might have placed the gut in danger of gangrene by deprivation of its blood-supply. When the injury had been less localised, such as that resulting from a fall or from being run over, it was possible that there might be a complication in the shape of rupture of one of the solid viscera, in addition to damage of the bowel and its mesentery. It had been observed that local tenderness was usual, but there might also be a sharp superficial tenderness extending from that towards a dependent part, indicating the direction taken by fluid of great irritative properties in its course to the flank or to the pelvis. Another symptom of importance was a marked rise of temperature within a short time of the injury. Mr. Battle considered that the loss of liver dulness as a sign of ruptured intestine was useless. It was rarely seen. Emphysema of the sub-peritoneal tissue was met with mostly in cases of rupture of the duodenum during the course of an operation for that lesion. The mortality was less when early operation was performed, but the best results were obtained when it was done between 7 to 12 hours after the accident. By operation in cases of ruptured intestine was understood abdominal section, a search for the injured gut, and its repair by suturing. In some it might be necessary to excise the contused and lacerated part and perform an anastomosis. Mr. Battle, in discussing rupture of the spleen, said that Dr. White-Hopkins, who had spent some years in Sarawak, had kindly permitted him to show them a weapon which he (Mr. Battle) called the "lethal cross," but the real name of which was "Larang" (meaning forbidden) in Malay. It was carried with the shaft up the arm of a long sleeve, clutched between the second and third fingers at the cross, leaving the knob extending. It could not be seen in consequence of the sleeve. The assassin waited for his victim at night, and accosting him dealt him a sudden and unexpected blow in the abdomen, and was not particular as to the position in which he struck. The victim without a groan fell dead on the spot. His pockets were rifled, and nothing more was known of his assailant.

The conversazione which followed the oration was attended by a great company of friends and members of the society, the official reception by the President taking place on the spacious landing between the library and the lecture hall. In the course of the evening Sir William S. Church was admitted an honorary member of the society.

EDINBURGH OBSTETRICAL SOCIETY.

Suprapubic Transverse Fascial Incision.—Bacillus Coli Infection of the Urinary Tract in Pregnancy.

A MEETING of this society was held on May 11th, Dr. F. W. N. HAULTAIN, the President, being in the chair.

Professor J. A. C. KYNOCH (Dundee) read a paper on Suprapubic Transverse Fascial Incision in Gynæcological Cœliotomy. The linea alba, he said, although the weakest part of the abdominal wall, is still the favourite line of incision, doubtless on account of its sparse vascular and nerve supply. Many operators are quite satisfied with the results. Howard Kelly, with an experience of over 2000 cœliotomies through the linea alba, has no reason to distrust it on the ground that the cicatricial union is less firm and secure than in those cases where the incision is lateral to the median line. To lessen the tendency to hernia other operators have employed an extra-median incision along the linea semilunaris; but Mikulicz has shown that such an incision, dividing the terminal branches of intercostal nerves, may result in paralysis and atrophy of the corresponding rectus muscle and thus favour the development of subsequent hernia. Dr. Kynoch has followed Pfannenstiel's method of slightly curved transverse incision about six centimetres above the pubes, through the skin and anterior sheath of both recti muscles; the anterior sheaths are bluntly dissected off the recti muscles, the recti are drawn aside, and the peritoneum is divided externally to the linea alba. After closing the wound the result of such an incision is that the transverse fascial wound is protected by intact muscle. The advantages claimed are chiefly the avoidance of post-operative hernia; the reports of Pfannenstiel, Doederlein, Menge, and others support this. The field of operation, especially the lateral and anterior part of the pelvis, is very accessible; the muscles are readily drawn asunder. Patients can rise sooner, as the intra-abdominal pressure does not to any extent affect the skin and fascial incision. This method is suitable for small tumours, cysts of moderate size, non-suppurative diseases of the appendages, and ventro-fixation of the uterus. Cases suspected of being infective are unsuitable. With few exceptions it is the method of opening the abdomen most frequently employed in German cliniques, and in many it is used for large tumours.—The PRESIDENT, Dr. A. H. F. BARBOUR, and Dr. W. FORDYCE discussed the paper, and Professor KYNOCH replied.

Dr. E. NAPIER BURNETT (Newcastle-on-Tyne) read a paper on Bacillus Coli Infection of the Urinary Tract complicating Pregnancy. After detailing four cases met with in his practice, Dr. Burnett stated that the acute disease often begins with rigors and a high temperature, accompanied with diffuse abdominal pain which soon becomes restricted to the right renal region; nausea and vomiting are not infrequent. The tongue is furred and constipation is usually present. Bladder symptoms, such as frequent micturition and dysuria, may be present, or only renal disturbance with few, if any, bladder symptoms. The urine is scanty and high-coloured. The abdominal muscles are rigid on the right side. The patient complains of pain possibly in three sites: most commonly over McBurney's point, over the bladder if that organ is affected, and, what is characteristic though less frequently present, extreme hyperæsthesia over a wide area in the region of the right kidney. Per vaginam, the bladder may be tender over the whole of the posterior wall, but especially over the trigone area. In many cases there is found a very tender spot just at the site of entrance of the right ureter into the bladder; the ureter may be thickened or dilated and readily palpable. The temperature may rise to 104° F. and fall in the morning to 99°; after a few days it may remain continuously high, indicating some involvement of renal tissue or of the opposite urinary tract. The patient with continuous high temperature develops a poisoned look, and more or less delirium may be present. The urine may have no characteristic smell, certainly no fæcal odour and no ammoniacal odour, as the B. coli has no power to split urea. The urine is most frequently turbid, due partly to mucus from the associated catarrh and also to flakes of lymph, shreds of epithelium, and pus cells. In simple cases with no inflammatory lesion and where the organism is not very abundant the urine may be perfectly clear. The urine is invariably acid, at least when the B. coli is present in pure culture, but if the infection is mixed with staphylococci or streptococci then the urinary reaction may be neutral or alkaline. The reaction of the urine does not depend on the site of the inflammation, but on the nature of the organism causing the infection. Albumin in small quantity is usually present from the admixture of pus or blood. The only method of definitely distinguishing the source of pus is a careful study of the clinical symptoms, with a cystoscopic examination and ureteral catheterisation. The course of the acute disease, if untreated, extends to several weeks, with a deepening toxæmia and repeated rigors, and possible abortion. In chronic cases the onset is more insidious; malaise is present, with muscular pains and persistent irregular temperature; bladder symptoms may be slight or absent. Pain and tenderness of the structures overlying the kidney and ureter are always present, but not nearly so marked as in acute cases. Headaches and general ill-health, with some albuminuria, may lead to the diagnosis of a pre-eclamptic state unless a careful examination of the urine is made. Slight cases are often overlooked. A pregnant woman complaining of intermittent attacks of lumbago with griping pains, especially over the right side, should have her urine carefully examined for B. coli infection. In the acute form the disease may be mistaken for acute appendicitis; one of Dr. Burnett's cases had been advised by a surgeon to be

operated on for appendicitis, and in two others he had seen the abdomen opened for appendicitis when a healthy appendix was found and the cases proved afterwards to be B. coli pyelitis. Tenderness over McBurney's point should not be considered pathognomonic of appendicitis. The condition may also be mistaken for acute intestinal obstruction, acute cholecystitis, malaria, pneumonia and pleurisy, or renal and ureteral stone. The treatment consists in rest in bed, attention to the bowels, bland diet, and diluent drinks. The most efficient drugs are alkalies; the citrates and acetates of potassium and sodium, when given in large doses frequently, exert a distinct control over the disease and cause a rapid subsidence of the most acute symptoms. Even in chronic cases the administration of these salts produces a marked diminution of the bacilluria. Urotropin and helmitol seem to have little effect on the disease if it is due to a pure culture of B. coli; but if mixed infection is present these drugs are of distinct value and ought to be used freely. Salol, sodium benzoate, and boric acid are not so satisfactory in their results. Serum treatment has not produced very decided results; one observer obtained valuable results in 12 cases from a vaccine prepared according to Wright's directions. A recent line of treatment is douching the pelvis of the kidney with an antiseptic through a ureteral catheter. In very severe acute cases where the ordinary palliative treatment has been unavailing, the pregnancy should be ended by operation rather than have recourse to a nephrotomy.—The PRESIDENT, Dr. JOHN THOMSON, Dr. BARBOUR, Dr. H. M. CHURCH, and Dr. FORDYCE made remarks on the paper, and Dr. BURNETT replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY.

Exhibition of Specimens.

A MEETING of this section was held on April 29th, Dr. T. H. MILROY, the President, being in the chair.

Professor JOHNSON SYMINGTON exhibited a number of skiagrams illustrating the Development of the Teeth in Primates, and also the relation of the teeth to the maxillary antrum.

Dr. L. L. CASSIDY exhibited a specimen of Superfœtation taken from a cat. It showed in one horn of the uterus a well-developed embryo 5 inches long and 6 or 7 weeks old. It possessed a fully formed placenta, an umbilical cord 4 inches long, and membranes complete. The other horn contained a much smaller fœtus 2 inches long, which was enveloped in its own bag of membranes. The uterine body was 1 inch long, ½ inch broad, and 1-16th inch in thickness. A septum divided it into two parts, extending to the external os. Decidua lined both horns. The right ovary showed a well-marked true corpus luteum, which was obviously of recent date, and accounted for the second embryo. The left ovary had a true corpus luteum, which was distinctly older than the one on the right side. The interest of the specimen lay in the fact that there were two embryos, one occupying each horn, and showing a great difference in period of growth. The smaller by no means represented a "blighted ovum," as both microscopically and on section it appeared quite normal. Dr. Cassidy said that superfœtation was of not infrequent occurrence amongst the lower mammals. Kroon[1] relates a case of a goat bred on Sept. 14th, 1897, œstrum and copulation recurring 52 days later. 152 days later she expelled three fully formed embryos, two living and one dead. Next day, when the membranes were expelled, three more perfectly formed, but imperfectly developed, embryos were discovered. Tapken, quoted by De Bruin, gives a case of superfœtation in a sow which was bred on Feb. 22nd, 1890. Œstrum and copulation occurred 14 days later. In the following June she gave birth to seven live pigs, and 14 days later to nine live and three dead pigs. Reasoning from these cases in mammals where a double uterus existed superfœtation seemed not alone possible, but extremely probable. Obstetrical literature contained several recorded cases of what presumably were instances of superfœtation, but whether true superfœtation occurred in the normal human uterus was very doubtful. In the 38 recorded cases of bicornuate uteri in women there was no case mentioned of superfœtation having occurred.

Mr. SETON PRINGLE read a note on a case of Complete Transposition of the Viscera. The condition was found in a man, aged 27 years, who was the subject of extensive cancer of the rectum. He opened the abdomen for the purpose of fully examining the extent of the disease, and, if removal was out of the question, of performing a colotomy. He found a transposition of all the abdominal organs, and as removal was impossible he performed colotomy, fixing a knuckle of the iliac colon in an incision in the right inguinal region. The heart was situated in the right thorax, the apex beat being in the fifth right intercostal space, 1¾ inches inside the nipple line.

Professor A. CAMPBELL GEDDES showed specimens and lantern slides of Developmental and Acquired Abnormalities met with in the dissecting-room during the winter session 1909–10. The first of these was an abnormal nasal duct, which opened into the middle instead of into the inferior meatus of the nose. On dissection it was found that there was a thin fibrous cord occupying the normal position of the duct. No record of a similar abnormality had been discovered in the literature. Other specimens were abnormal bicuspid teeth, an abnormal right lung, and several abnormal livers, one of which possessed no quadrate lobe, the ligamentum teres passing backwards immediately superior to the gall-bladder. At the close of his demonstration Professor Geddes showed a series of photographs to illustrate the mechanical effects of a massive pleural effusion.—Professor SYMINGTON said with reference to the pleural effusion, that in his opinion there was a very serious defect in the conducting of post-mortem examinations. It seemed to him that a great deal could be learned if some hardening fluid was injected and the organs were fixed in position. The object of the pathologist was to get the organs out of the body, and there was little attention paid to the topography of the body under pathological conditions.—Dr. THOMAS G. MOORHEAD said that extreme difficulty was found in carrying out Professor Symington's suggestion with regard to post-mortem examinations, which were generally done in a hurry, with friends waiting outside the door to inter the remains. As far as possible they aimed at letting the patient die with the fluid removed. When they did make use of a hardening agent it was found to defeat one of the main objects of a post-mortem examination—the finding of the cause of the pathological condition.

Dr. N. C. RUTHERFORD showed lantern slides of a Human Embryo of the Fifth Week. Such features as the proto-vertebral markings, the closing cervical sinus, the state of development and rotation of the limbs, the commencing appearance of the middle digit on the left side, indicated the age of the specimen as almost exactly the middle of the fifth week. He was of opinion that the embryo had no exact counterpart among those collected by Keibel and Hochstetter.

COMPETITION OPEN TO MEDICAL STUDENTS.—The Society of Medical Phonographers offers a prize of one guinea for competition amongst medical students for the best answers to three questions in medicine and surgery which are intended to appear in the August, October, and December issues of the *Phonographic Record of Clinical Teaching and Medical Science* (the organ of the society). The sole qualifications for entry for the above competition are membership of the Society of Medical Phonographers and ability to read shorthand (Pitman's system). Answers to the questions may be sent in in ordinary writing, typewriting, or shorthand at the option of the candidates. The above competition will take place if not less than four student members enter for it. Entries must be received on or before July 7th by the honorary secretary of the society, Dr. A. Hill Joseph, 10, Cantelupe-road, Bexhill-on-Sea, who will be glad to receive applications for membership. There will be no entrance fee. Student members of the Society of Medical Phonographers pay a subscription of 5*s.* per annum, in return for which they receive the *Phonographic Record of Clinical Teaching and Medical Science* as well as other literature issued by the society. Members of the profession pay a subscription of 7*s.* 6*d.* per annum. It is proposed later to institute another competition in anatomy and physiology.

Reviews and Notices of Books.

The Laws of Heredity. By G. ARCHDALL REID, M.B. Edin., F.R.S.E. London: Methuen and Co. Pp. 548. Price 21*s.* net.

Dr. Archdall Reid has attempted a very big thing in the work which lies before us. He has attempted to cover in one treatise the methods employed and the results achieved by the various schools who are working at the problem of heredity to-day. Do not let us give a false impression of the book. It is not the work of a compiler. The "laws of heredity" are not the various laws which have been formed by other people—Weismann, Mendel, Galton, and Pearson: they are the fundamental principles of heredity as conceived by Dr. Reid. So far from being a mere compilation the individuality of the author is writ large on every page of the book. We do not mean that it is our opinion that he has failed to attach due significance to the work of other men. So far from this being the case, he has an admiration for the writings of the logicians of the nineteenth century, the magnitude of which is reflected in the number of passages quoted, for instance, from the works of Mill, Jevons, and Whewell. Of many of his contemporary workers, on the other hand, Dr. Reid has a poor opinion. For the Mendelian workers and for the biometrical school he has some very hard words.

His two attitudes—to eminent logicians on the one hand and to present workers on the other—correspond to the two headings under which the ideas and material embodied in this book may be conveniently classified—namely, constructive and destructive. In the constructive parts he supports his own theories by ample quotations from other thinkers. In the destructive parts he dissects the experimentalists, the Mendelians, the biometricians, and the mutationists of the present day. It is our opinion that both sections of the work are of deep interest and value; but the value of the constructive part is very different from that of the critical.

Let us deal with the destructive or critical section of the work first. This is valuable, because in our opinion Dr. Reid really is a great critic. He has a piercing eye for disproportion, and he owes his power as a critic to the fact that he has not received a biological training in any of our universities or great scientific institutions. We recall a controversy in one of the monthly journals in which the following passage of arms occurred. A critic had asserted that Dr. Reid with all his astuteness was not a trained thinker. To this Dr. Reid replied that his critic with all his training was not an astute thinker. This reply was not only witty, but profoundly and valuably true. The author of "The Laws of Heredity" owes his astuteness in great part to the fact that he has not received the training to which the young man who decides to devote his life to the study of vital processes is compelled to submit, not only before he has taken his degree, but afterwards as well. He views the phenomena of heredity from the properly distant vantage ground of a man who accepts any relevant evidence without first inquiring the precise nature of the method by which it has been collected. The Mendelian thinks of heredity in terms of unit characters, segregation, and allelomorphs. The biometrician does not think about the facts at all until he has marshalled them on a correlation table. Members of these schools are too close to the phenomena they investigate, and too fond of the method by which they investigate them, to be able to detach themselves sufficiently from either, and thus to be in a position from which the whole range of hereditary phenomena at present known to us can be seen. We think that Dr. Reid's claim that he can take this comprehensive view of the subject-matter of his book is justified.

Let us glance at the two subjects which Dr. Reid has examined critically and with results which deeply concern the medical practitioner and the professional biologist—namely, the question of the inheritance of acquired characters and the Mendelian theory of heredity. Workers familiar with hereditary processes have long realised that the controversy which has raged over the question whether acquired as well as innate characters are inherited is a fictitious one in the sense that it has resulted from the use of terms which have conveyed the ideas they were intended to convey very imperfectly. Indeed, so ill-chosen have the terms used in this controversy been that it is not surprising to hear the view expressed that it is no more than a dispute as to the meaning of terms. Dr. Reid's achievement has been to discern the real point at issue and to clothe it in a phraseology which bears a closer relation to actuality than, for instance, the worn-out terms "acquired" and "innate." We are not by any means of the opinion that Dr. Reid's statement of the problem is final. But as a provisional clearing of the ground we think it serves a very useful purpose. The distinction between innate and acquired characters is a foolish one, because all characters are acquired and they are also all innate. The characters of an organism do not differ from one another in the degree of their innateness (if the term may be allowed), because all characters depend for their existence on the response made by an inherited or innate potentiality in the germ to an external stimulus. Every character of an organism that we can think of is acquired at some stage during the process of development. This is obviously so; the germ cell possesses none of the characters which distinguish the organism which develops from it. It may be objected that the germ cell possesses them *in potentiâ*. Precisely. It does. And this is only another way of saying that a character is acquired during development as the result of the response by an innate potentiality to an external stimulus.

Characters differ from one another according to the nature of the stimuli which are necessary to call them forth. These, according to Dr. Reid, are Nutriment, Use, and Injury. What we mean when we speak of innate characters are characters which arise in response to the stimulus of nutriment. What we mean when we speak of acquired characters are those which arise in response to the stimulus of use or of injury. If we hold that an oarsman who doubles the size of the muscles of his back will have a son whose back muscles will, even if he himself does not row, start with the strength acquired by his father—if we believe this, we have to believe that a character which appears in one generation in response to the stimulus of use appears in the next in response to the stimulus of nutriment. It is transferred from one category to another. Dr. Reid says not only that this does not happen, but that it would be a most disadvantageous thing if it did. A character which develops only if, and to the extent to which, it is wanted is a much more convenient thing than one which develops to its fullest extent anyhow, that is to say, if it receives the nutriment necessary for its development. The possessor of a character of the former type is like a man with £50,000 in the bank and a cheque-book; a possessor of the latter type only is like a man doomed to carry that sum about him in gold.

Now with regard to Dr. Reid's critique of the Mendelian hypothesis. It is well known that perhaps the most interesting application of the Mendelian principles of inheritance is the attempt which has been made to interpret the phenomena of sex by the conceptions of unit characters and segregation. The series, as read by the Mendelian, begins with

varietal, non-sexual characters, and culminates in the sexual ones. Dr. Reid's view is expressed epigrammatically by him as follows. Mendelians, he says, have suggested that the inheritance of sexual characters is Mendelian; we shall be much nearer the truth, he holds, if we say that the inheritance of Mendelian characters is sexual. He reads the series of the Mendelian backwards—from the Mendelian's point of view. He thinks the Mendelian has got hold of the wrong end of the stick. Sexual characters are older than Mendelian ones, which occur almost exclusively in the domestic state. The mode of inheritance of sexual characters is the starting point; Mendelian phenomena are anomalous hereditary processes which have nothing to do with the main line of racial descent; they owe their existence to the transference, in the domesticated state, of the alternative mode of inheritance which was primarily evolved in connexion with sexual characters to isolated varietal characters, most of which are closely associated with secondary sexual characters. What is the mode of inheritance of sexual characters? Why do Mendelian characters occur only in domesticated breeds? Why are latent characters very rarely, if ever, revealed when natural varieties are crossed? These are questions the answers supplied to which by Dr. Reid form some of the best reading in his book. What is the function of sex? In his answer to this Dr. Reid proceeds, in our opinion, far in advance of established facts.

This brings us to a consideration of the constructive part of the book. Dr. Reid is very sanguine about the value of the results which can be achieved by thinking. Those who are equally sanguine will enjoy this part of the work. "The method of work on which I insist," says Dr. Reid, "is no new thing. It is the method which has been proclaimed as the only right one by every authority who has both thought and expressed himself on the subject; it is the one which has been followed by every great scientific worker; it is the one by which the truth of every law of nature known to us has been established. At the risk of tiresome reiteration this method of work may be indicated as follows:—When, as in the study of heredity and evolution, we wish to establish the relations between facts that occur in sequences (i.e., when we wish to discover chains of cause and effect), we must formulate hypotheses. But hypotheses are mere guesses until they have been tested and found to be true. They can be tested only by making deductive inferences of consequences from them and appealing to reality to ascertain if these consequences actually follow. If a hypothesis enables us to predict correctly in this way, then it is in all probability true; and it is the more certainly true (and useful) in proportion to the number of different correct predictions it enables us to make—in proportion as it accords with the whole universe of relevant truth. Moreover, such deductive appeals to reality not only enable us to test hypotheses and so convert them into laws, they not only enable us to bring within the range of each real law masses of data which had not been used for the corresponding hypothesis, but they enable us to perceive the relations between the several laws, and so, by linking the laws together, to advance towards that harmony of knowledge which is one of the principal aims of science." For our own part, a distrust of the ratiocinative faculty, begotten of a deep interest in the process itself of the interpretation of natural phenomena, and of a sufficient familiarity with its history, prevents us from sharing this sanguineness. But those who think as Dr. Reid does may be less remote from the truth.

In his vindication of the value of deduction Dr. Reid says: "Scientific deduction, like scientific induction, differs from our common use of the process only in the greater precautions we take to make it accurate. It would be strange if a process, so useful and necessary in the ordinary affairs of life, should become valueless and dangerous the moment we endeavoured to use it with care, and if men, to become scientific, must cease to be rational." Certainly it would be strange. Great changes when they occur are strange. There are signs that this change may be not far off. Indeed, one of the fundamental tenets of the philosophy of one of our greatest modern philosophers—M. Henri Bergson—is that the rational faculty which has been evolved to deal with the practical affairs of everyday life is entirely unsuited for prosecuting the quest for truth. We can imagine no more valuable mental exercise than the attempt to master the point of view set forth in Dr. Reid's "Laws of Heredity" and that in M. Bergson's "L'Evolution Créatrice."

The constructive part of Dr. Reid's book is interesting because it represents, to our mind, the maximum that can be achieved by painstaking thinking, and because it is the last attempt to base an explanation of the process of evolution on the doctrine of Natural Selection. Just as Dr. Reid does all that he can with Reason, so he does all that can be done with Natural Selection—which, in his belief, is practically everything. Adaptation is, he says, the anchor around which the thoughts of the student of evolution must ever swing. He has taken the step from which Darwin shrank, and has made Natural Selection, if not the cause of variation, at any rate that which determines its amplitude and extent. The function of sex is elucidated by showing the useful part played by bi-sexual descent. If Natural Selection is valid, Dr. Reid will have demonstrated its validity; if it is not, Dr. Reid will be responsible for its explosion. For he has led that doctrine to its logical conclusion.

Dr. Reid draws a distinction between facts patent and obscure. The former can be seen by everyone, the latter can only be revealed by the exercise of difficult and tedious experiment, and he is critical of those who lay undue stress on the facts brought to light by the latter method. He thinks it unfortunate for the experimenters to have to spend so much time in finding things out in these cumbersome ways, but allows that the particular facts cannot be found out in any other way. Dr. Reid here loses sight of the point that scientific men do not always employ the methods with which they grow familiar, because they want to discover the truth, but sometimes because they like those particular methods. If Dr. Reid discovered that the truth could be swiftly and surely reached by the process of Mendelian analysis, which is not likely, he would not prosecute Mendelian studies. The error into which Dr. Reid falls here is a result of that utilitarian aspect of vital activity to which the doctrine of Natural Selection makes an irresistible appeal. We consider this to be the defect in his position, and we wish to remind the reader that there are many intelligent men who do not, for instance, regard reason as the sole, or even always a suitable, instrument for elucidating the truth, while there are others equally intelligent to whom the whole mechanistic view of life which underlies the doctrine of Natural Selection is extremely repulsive. But be this as it may, Dr. Reid is the most authoritative medical writer on heredity, and no one who wishes to keep abreast of current thought can afford to be without "The Laws of Heredity."

There is an appendix, entitled "An Attempt to Represent Diagrammatically some of the Ideas connected with Inheritance," by Professor H. H. Turner. It is written with the idea of making the theses embodied in the book interesting to mathematicians.

Gynécologie Médicale: Traitement Médical des Maladies des Femmes. By Professor ALBERT ROBIN and Dr. PAUL DALCHÉ. Third edition, revised and enlarged. Paris: Vigot Frères. Price 12 francs.

THE authors of this work believe, and to a large extent we agree with them, that the medical treatment of gynæcological cases has become somewhat obscured of late years by the enormous strides which have been made in the surgical treatment of these affections. They maintain that there is still room for the medical treatment of many of these cases and that the treatment of the various diseases of women should not be allowed to become purely surgical in character. Further than this, a good knowledge of gynæcology is essential for the general practitioner, and he must be acquainted with the various means of treating such cases without the assistance of the surgeon. Certainly, if we may judge by the size of this book, medical gynæcology is a subject of considerable importance, and yet when we examine what the book really contains we are led to the conclusion that the authors might have compressed what they have to say into a much smaller compass.

The first part of the book deals with what they term "Fausses Utérines," that is to say, the various affections of other organs of the body which can simulate uterine disease or can cause symptoms referable to the pelvic organs but not pelvic in origin. It is, of course, well known to every practitioner of experience that pelvic symptoms may accompany a variety of other diseases; for example, we may instance the effect of the nervous system upon menstruation, the influence of heart disease in producing hæmorrhage from the uterus, of anæmia in causing amenorrhœa, of the acute specific fevers in the production of endometritis, and of the abuse of alcohol and of pelvic congestion the result of constipation in aggravating ovarian pain. When we consider, however, how relatively small a part these pelvic symptoms play in the various diseases we have mentioned, and how every patient who is at all out of health is likely to suffer some slight derangement of the functions of the pelvic organs, it appears to us hardly worth while to devote, as the authors have done, some 134 pages to a consideration of these conditions. The authors may feel that it is necessary for the French practitioner to have his attention more especially called to these facts, but their importance can well be exaggerated, and to English students their relative insignificance is well known.

After the section devoted to the "Fausses Utérines" the authors discuss menstruation and its accidents, including a consideration of puberty, the treatment of dysmenorrhœa and amenorrhœa, and the menopause. There is also a chapter on the treatment by ovarian extract of a large number of varying affections. Apparently the authors recommend this form of treatment in such different disorders as anæmia and menorrhagia, chlorosis, Graves's disease, obesity, and chronic rheumatism, as well as in various forms of mental disturbance. Our own experience of this therapeutic measure has not been very favourable.

The next section deals with the different maladies of the vulva, the vagina, the uterus and its appendages, and details very fully indeed all the therapeutic remedies which can be employed in dealing with them. Some 50 pages are devoted to a consideration of so-called metritis. It is a little difficult to determine exactly what the authors mean by the term metritis. Their pathology is a little out of date, and we find that they quote, apparently with approval, such views as those of Aran, who attributed metritis to constipation, and Gaillard Thomas, who thought it due to feebleness of the constitution or to deprivation of air and exercise. The authors, like many other writers on gynæcology, use the terms endometritis and metritis in a very loose and unscientific manner, and as they give them such a very wide meaning it is not surprising that their therapeutic measures are exceedingly various.

It would have increased the value of the work if a little more attention had been paid to modern pathology, and if more precision and selection had been exercised in the sections dealing with the supposed etiology of these different affections. It is interesting to note in this connexion that in the report of the in-patient gynæcological department of a large London hospital for the year 1908 not a single case appears to have been diagnosed or treated as metritis. No doubt this may be merely a question of terms, but it serves to point an interesting contrast between the teaching of the authors of this work and that of the well-known gynæcologist who has charge of the department we have alluded to.

The last part of the book contains a very long and detailed description of the different methods of treating affections of the pelvic organs by hydrotherapy. Every variety of water is discussed in detail and all the methods in which it may be employed, and while much of this section is interesting it can be of but little utility to the practitioner.

The whole book appears to us to have been written without a due sense of proportion: the value of the medical treatment of pelvic affections is exaggerated, and the authors base many of their recommendations upon a pathological foundation which is largely supposititious and not in accord with modern teaching.

La Période Post-opératoire: Soins, Suites, et Accidents. Par Dr. SALVA MERCADÉ, Ancien Interne Lauréat des Hôpitaux de Paris. With 82 figures. Paris: Masson et Cie. 1910. Pp. 553. Price 12 francs.

THE aim and scope of this book, which deals with the after-course and care of patients recovering from operations, are most excellent. It ought to prove of utility to those in general practice who have such patients left in their charge after a specialist has been called in for the operation. The arrangement of the various subjects is good, the writing is clear, and the get-up of the book is attractive. Professor Lannelongue introduces the author and his subject by remarking that the various treatises on systematic and operative surgery leave a gap which this book is designed to fill.

The first chapter is a somewhat meagre general account of the condition and care of the patient after an operation. It is of questionable value to insert in a brief summary such a statement as that "if in spite of all these measures post-operative anuria persists, nephrostomy should be performed without hesitation." The complications due to anæsthetics and antiseptics are considered in detail. Chloroform is mentioned as the most frequently used general anæsthetic; anæsthetic vomiting is described without discussing how it is to be distinguished from vomiting due to peritonitis or intestinal obstruction; acidosis, acetonuria, and late chloroform poisoning are all separately described as if they had no connexion, and the treatment of these conditions by the injection of alkalies is not mentioned. Bronchitis is said to be rare after ether, but pneumonia common, and no distinction is made between the closed and open methods of giving this anæsthetic. The fourth chapter treats of the local and general complications after operations, and here as elsewhere there is a lack of precise directions for treatment, which should be the first aim of the book. Much stress is laid upon the injection of collargol in septic conditions, but the use of vaccines and serums is omitted. The remaining chapters describe the course and complications following the various procedures of regional surgery. It is possible that these are a good representation of French methods, but they certainly teem with

matter requiring criticism chiefly on the score of omission from our point of view. For instance, reference is absent or scanty with regard to the following: keratitis after the removal of the Gasserian ganglion; nasal feeding after operations for cleft palate; gland removal in cancer of the tongue; the necessity for peptonisation or citration of milk used for feeding patients after stomach operations; the relation of hæmorrhage after gastro-enterostomy to the use of anastomosis forceps; the advantages of the Fowler position after gastric operations; the treatment of ruptured gastric ulcers and the occurrence of subphrenic abscesses; the use of Paul's tube in colostomy; the occurrence of urinary fistula, mania, and retention of urine after prostatectomy; and the posture of abduction necessary after excision of the hip. Comparatively rare or doubtful operative sequelæ—e.g., the occurrence of exanthemata and the atrophy of the testes after removal of tonsils, acute dilatation of the stomach after laparotomy, and kraurosis vulvæ after hysterectomy—are discussed at disproportionate length. To say (see p. 416) that after prostatectomy the bladder functions are perfectly resumed and that the patients pass urine well and never suffer from a recurrence of their former symptoms is, we venture to think, an unfairly optimistic statement, for which no doubt certain English surgeons are in large degree responsible.

We have pointed out frankly what we consider omissions; in spite of them the book is of real value, which no doubt will be enhanced by revision and additions in a subsequent edition.

Urgent Surgery. By FELIX LEJARS, Professeur Agrégé à la Faculté de Médecine de Paris, Chirurgien de l'Hôpital Saint-Antoine, Membre de la Société de Chirurgie. Translated from the sixth French edition by WILLIAM S. DICKIE, F.R.C.S. Eng., Surgeon, North Riding Infirmary, Middlesbrough; Consulting Surgeon, Middlesbrough Union Infirmary; Consulting Surgeon, Eston Hospital. With 20 full-page plates and 994 illustrations. Vol. I., Introductory, Head, Neck, Chest, Spine, Abdomen. Bristol: John Wright and Sons, Limited. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1909. Pp. 617. Price 25*s.* net.

WE have on several occasions spoken very favourably of the well-known work of Lejars, "Chirurgie d'Urgence," and we extend a cordial welcome to this presentation of the work in an English dress. The excellence of the text, the clearness of description, the fulness of the suggestions for treatment, and the abundance of illustrations should ensure the success of the book in this country. In emergencies the technique of an operation may have to be learnt with but little time for preparation, and though the skilled operating surgeon is ready for all that may come before him, those who have had but little experience in the practice of surgery will find great value in having a trustworthy text-book to consult in moments of need; and they can have none more trustworthy than the work before us. The mere fact that the original has reached the sixth edition within a few years will show how great has been the success the work has attained in the country of its origin, and this success has been well deserved. We would especially draw attention to the completeness with which the subjects are treated. We may quote as an instance of this the account of the equipment of the surgeon, and the description which is given of the method of procedure in a case of extreme urgency with a complete lack of necessaries. Illustrations are given of what may be thought simple matters, such as how the nails should be cleansed for an operation and how a basin of lotion should be held. The volume under review contains only half of the original, the remainder being about to appear in the second volume. We have here an account of the urgent surgery of the head, neck, thorax, pharynx, and abdomen. It is, of course, by no means easy to draw a sharp line between surgery that is urgent and that which is not, but we think Lejars has acted wisely in interpreting urgency somewhat widely. For the translation we have nothing but praise. The English is idiomatic and betrays rarely its origin.

A Manual of Diseases of the Nose and Throat. By C. G. COAKLEY, A.M., M.D., Professor of Laryngology, University and Bellevue Hospital Medical College, New York. Fourth edition, revised and enlarged. With 126 figures and 7 coloured plates. London: Henry Kimpton. 1909. Pp. 604. Price 14*s.* net.

NO book arrives at its fourth edition without a reason, and this manual has merits which will recommend it to the student of laryngology. The first two chapters deal with the anatomy and physiology of the upper respiratory tract. Antisepsis is the theme of the third chapter, one which we hope is less necessary every edition, as the younger members of the profession learn the lessons of asepsis and antisepsis so much more thoroughly than was the case 20 years since. Nasal obstruction is dealt with in the fourth chapter briefly, more as a grouping together of all possible causes than as a complete dissertation on the subject, for the various diseased conditions of which nasal obstruction is a symptom are naturally discussed seriatim. The next 50 pages are occupied by the different forms of rhinitis; the section on hypertrophic rhinitis might be enlarged with advantage, for it is the form most commonly seen by the general practitioner. The only operation on the septum alluded to is that of submucous resection, which is not sufficient, for there exist many deformities which may be corrected by simpler and easier procedures. Diseases of the antrum are illustrated by several coloured plates showing the effects of transillumination on diseased and healthy antra. Diseases of the pharynx, tonsils, and the adjacent parts are very clearly described, and a decided preference is expressed for excision of the tonsils. Diphtheria, tuberculosis, and syphilis of the nose, pharynx, and larynx are dealt with in a very able manner, as are all the various pathological lesions of the larynx. There is at the end of the book a chapter on therapeutics which will be found of great assistance to practitioners.

Dr. Coakley's book is of the right size for the practitioner, it is clearly written, not too deep, and essentially practical.

Operations on the Ear: The Operations for Suppurative Otitis Media and its Intracranial Complications. By B. HEINE, Professor of Otology in the University, and Director of the Otological Polyclinic in Königsberg, Prussia. Translated and edited from the second German edition by W. LOMBARD MURPHY, M.B., B.C. Cantab., F.R.C.S. Irel., Surgeon to the Throat and Nose Department, St. Vincent's Hospital, Dublin. With 56 illustrations. London: Baillière, Tindall, and Cox. 1908. Pp. 204.

Professor Heine, besides detailing the various operations on the ear, goes also fully into the indications for each operation. The first series of operative procedures is that affecting the tympanic membrane, where a transverse incision is recommended. In describing the operation for removal of the ossicles it is advised that the ear be not cleansed immediately before the operation, but syringed, then swabbed with sublimate solution, and packed with iodoform gauze. This seems likely to leave an operation cavity unnecessarily septic, especially as the immediate after-treatment advised, subsequent to removal of extravasated blood, is merely packing with iodoform gauze; but in respect to the small value of the operation Professor Heine is in agreement with the majority of aural surgeons. Under operations on the mastoid process full

descriptions of the two procedures most commonly in use—opening of the antrum for acute mastoid disease and the radical operation—are well and clearly described, though here again the use of a strong antiseptic to the cavity is omitted in accordance with a prevailing custom in many parts, at least on the continent, which would explain the relatively great frequency of post-operative labyrinthitis abroad. The frequency of fistulous openings into the external semicircular canal is pointed out, and a strongly worded opinion is given as to the advisability of leaving these fistulæ untouched when the symptoms show no indication of general labyrinthine infection. Professor Heine also considers that labyrinthine operations cannot be termed safe, but that there is always a risk to the patient.

Sinus thrombosis and pyæmia are much more fully detailed than is usual, and some very pertinent remarks are made on the subjects, but the suggestion to expose the sinus in every case of suppurative otitis media when a sudden rise of temperature occurs and where the exanthemata can be excluded is too sweeping. Professor Heine advocates the non-removal of benign thrombus, but treats the sinus like an abscess, with incision and plugging. He also takes a very unbiased view as to the advisability or otherwise of tying the jugular vein as a regular rule in septic thrombosis of the sinus, but is fully in favour of exposing the bulb when necessary. The operations for cranial abscess and for meningitis complete the book.

To those who wish to have a good *résumé* of the views of German aural surgeons with regard to operations on the ear we can recommend the present treatise as a very comprehensive one, but it may be remarked that there is no reference to the work of any British aural surgeon. The translation is fairly good, and the matter is presented in a very interesting way.

LIBRARY TABLE.

Constipation and Intestinal Obstruction (Obstipation). By SAMUEL GOODWIN GANT, M.D., LL.D., Professor of Diseases of the Rectum and Anus in the New York Post-Graduate Medical School and Hospital. With 250 original illustrations. London and Philadelphia: W. B. Saunders Company. 1909. Pp. 559. Price 25*s.* net.—It might be thought in these days of pills and aperient mineral waters that there was little risk of under-estimating the importance of constipation. But with the public all forms of constipation, whatever the origin, are treated by means of some aperient, more or less drastic, and only too many medical men hold similar views. There is, therefore, ample scope for a work which deals fully with what may be called the non-medicinal treatment of constipation, and in this work Dr. Gant describes adequately those methods of treatment of constipation which do not consist in the administration of drugs; thus we find described the employment of diet, hydrotherapy, exercise, and massage. The book also deals with the surgical treatment of all forms of intestinal obstruction, both acute and chronic, arising from mechanical causes; and thus many intestinal operations are described. An adequate number of illustrations is provided, some of them borrowed from the author's treatise on the rectum, and altogether we can speak very favourably of the work. We commend it to the attention of those members of the profession who are dissatisfied with the drug treatment of habitual constipation.

The Laws of Life and Health. By ALEXANDER BRYCE, M.D. Glasg. London: Melrose. 1910. Pp. 421. Price 7*s.* 6*d.* net.—There are few things which show more plainly the altruism of the medical profession than the constant stream of books written by medical men on the broad subject of how to keep well. Possibly in a few hundred more years Western nations will attain to the enlightened state of matters existing, according to travellers, in China and Persia, where medical men are retained not so much to serve in case of illness but to keep their clients in a state of good health. Only recently we reviewed a book by an American physician upon this subject, and the book before us deals with the same matter. Shortly, it may be said that the author has taken the "six non-naturals" of mediæval physicians—namely, food, exercise, rest, the excretions, air, and the passions. Each chapter has for a heading one of the laws mentioned in the title. Some of these are very general, but are dealt with more in detail in the chapter to which they belong, and every chapter is provided with a tabulated summary at its finish. Taken as a whole the book is a good one, but in places it bears evidence of hasty writing. For instance, on p. 106 Dr. Bryce says: "One per cent. of sherry in the stomach contents entirely stops digestion, a result which is probably due to the acid content." We cannot consider this statement as accurate. Again, on p. 48, in talking of eggs he says: "One-tenth is shell, six-tenths is white of egg or pure egg albumin, and three-tenths is yolk." Why should the water be entirely ignored? One of the best chapters is that on rest, which includes a discussion of rest for the eyes and ears as well as for the body and mind in general. Another chapter containing much sound advice is that upon cheerfulness, although many of the precepts may be found by those who endeavour to practise them counsels of perfection. In the next edition the misprint on p. xviii. of the introduction, where Sir Rubert Boyce appears as Sir Rupert Boyce, should be corrected.

The Police Officer's Guide to the Children's Act, 1908. By W. B. GENTLE, Chief Constable of Brighton, and C. A. RAWLINGS, solicitor. London: Effingham Wilson. 1909. Pp. 32. Price 1*s.* 6*d.* net.—This little pamphlet gives in a simple tabulated form the salient points of the "Children Act, 1908." The Act is a complicated affair, and its provisions cover very diverse ground. This abstract has therefore been drawn up for the assistance of police officers, and forms a clear and simple guide which should undoubtedly be of great value to those officials. It would also be useful to police surgeons and to general practitioners, who should, if they are wise, always procure copies of, or guides to, new Acts of Parliament which affect questions of offences against women and children. There is an addendum to the volume by Mr. C. A. Rawlings of a similar tabular form dealing with other Acts, including the Midwives Act, 1902, the Prevention of Cruelty to Children Act, 1904, and the Motor Car Act, 1906, all of which are of interest to medical men.

Jahreskurse für Ärztliche Fortbildung. In 12 monthly parts. Price 16 marks per annum. Munich: J. F. Lehmann.—The April number is devoted to a consideration of the recent advances in syphilology and diseases of the kidneys. Professor Neisser and Professor Siebert give a most excellent *résumé* of the former subject. The causation of syphilis by the spirochæta pallida is first considered. A very simple method of demonstrating the spirochætæ is by the use of Chinese ink. The organisms show up as light filaments against the dark background thus provided. The inoculation of apes has produced syphilis exactly similar to that in human beings except that the deep visceral lesions are not found. The uselessness of excision of the primary chancre to prevent the dissemination of disease has been experimentally demonstrated in animals, in which it is proved that constitutional infection occurs before the primary lesion becomes manifest. As regards the prevention of syphilis, dilute solutions of mercurial salts are held to be much more efficacious than Metchnikoff's original calomel ointment. The most valuable part of this section is that dealing with Wassermann's reaction. The method by which it is carried out and the principles underlying it are

explained with masterly simplicity. In spite of the fact that certain other diseases—e.g., frambœsia, leprosy, malaria, and scarlet fever—also give a positive reaction, this test is held to be of the utmost importance in the diagnosis of syphilis, especially in its late and latent forms. In the primary stages it may be obtained in about 70 per cent., in the secondary stages in 94 per cent., and in the tertiary stage in about 78 per cent. of cases known to be affected with the disease. The manner in which a positive reaction can be followed by a negative as the result of energetic mercurial treatment is of great interest and value in estimating the effectiveness of a cure. The value of the reaction in relation to the marriage of syphilitics, the employment of wet-nurses, and the detection of hereditary syphilis is critically considered. A full list of references to the literature on this subject is added. The section on Albuminuria and Nephritis by Professor Klemperer deals chiefly with the distinction between functional and organic affections, the question of salt-free diet in the treatment of nephritis, and a consideration of the more recently invented diuretics.

Guide to the Libraries of London. By REGINALD ARTHUR RYE. Goldsmiths' Librarian of the University of London. London: University of London. 1910. Pp. 206. Price 2*s.* 6*d.* net.; 2*s.* 10*d.* post free.—This the second edition of this excellent "Guide to the Libraries of London" is more than double the size of the earlier edition, and in concise yet not too brief manner indicates what each library in London contains on its shelves and to what extent those shelves are open to the use of the public. The book deals with general libraries, special libraries, and libraries of educational institutions, and will be found useful both to the general reader and to the student of special subjects. The author has kept very strictly to his intention of writing a general guide, and has not allowed any predilections for manuscripts or early printed volumes to take up space to the detriment of the value of all-round information. By the way, is it correct to say that the archives of the diocese of London are kept at Fulham Palace? Surely the series of episcopal registers have long been kept in St. Paul's Cathedral. The volume contains 16 photographs, which mostly represent the interiors of the different libraries of the metropolis.

JOURNALS AND MAGAZINES.

The Quarterly Journal of Microscopical Science. Edited by Sir RAY LANKESTER, K.C.B., F.R.S., with the coöperation of ADAM SEDGWICK, M.A., F.R.S., SYDNEY J. HICKSON, M.A., F.R.S., and E. A. MINCHIN, M.A. London: J. and A. Churchill. No. 217 (Vol. LV., Part I.), New Series. April, 1910. Price 10*s.*—The contents of this number are: 1. On the Anatomy and Systematic Position of Incisura (Scissurella) Lytteltonensis, by Gilbert C. Bourne, Linacre Professor of Comparative Anatomy in the University of Oxford, with five plates. Certain characters were noted as long ago as 1893 by E. A. Smith in Scissurella lytteltonensis which have led C. Hedley to form a new genus on account of the brevity of the slit in the shell, the absence of raised rims or keels on either side of the slit, the subterminal apex, the absence of spiral sculpture, and the remarkable solidity of the shell. He proposed for the new genus the name Incisura. Professor Bourne thinks this genus should stand, and in support of this view gives a full description of the anatomy of the Incisura lytteltonensis which is found on the seaweed Cystophora in rock pools in Lyttelton Harbour in Tasmania. 2. The Eye of Pecten, by W. J. Dakin, M.Sc., Assistant Lecturer in Zoology, University of Belfast, with two plates and two text-figures, which is referred to at some length on p. 1488 of our present issue. 3. Observations on Certain Blood Parasites of Fishes occurring in Rovigno, by Professor E. A. Minchin and H. M. Woodcock, D.Sc., with three plates. The authors state that the objects of this paper are twofold. The first is the description of a hæmogregarine and a trypanosome occurring in a species of gurnard (Trigla lineata) common in the Northern Adriatic. The hæmogregarine they regard as a new species, which they propose to call Hæmogregarina rovignensis. The second object they have in view is the comparison of the minute structure of the nucleus of the above-mentioned hæmogregarine with that of the trophonucleus of a trypanosome. They think, and give reasons for their opinion, that they are of two very different types. The former they find to be characterised by its chromatic reticulum with chromatic grains or masses more or less frequently distributed upon it. In the latter the greater part, or nearly all, of the chromatin is, as it were, condensed around a plastinoid basis, the whole forming the conspicuous karyosome, and in the centre of the plastinoid area is a definite granule, the intranuclear centrosome. 4. On Ganymedes Anaspidis, a gregarine from the digestive tract of Anaspidis tasmaniæ (Thompson), by Julian S. Huxley, with a plate and five text-figures. 5. The Fœtal Membranes of the Vertebrates, by A. A. W. Hubrecht.

Looking Back.

FROM

THE LANCET, *SATURDAY*, May 26th, 1832.

PROPOSAL TO FRANK ALL MEDICAL PERIODICALS.

To the Editor of THE LANCET.

SIR,—I observed in the title-page of the *Cholera Gazette*, "FRANKED to any part of the kingdom." Now it is not my wish or intention to quarrel with this piece of liberality, deeming it a very proper facility for circulating a publication which certainly *ought* to possess great value; but, Sir, as there are several weekly and monthly periodicals, wholly devoted to the purposes of disseminating equally, not to say more, useful medical information, I should very much like to know, why this boon of FRANKED might not be extended to them also? As the desire of doing good solely, no doubt, influenced this free transit of the Gazette, would not an extension of this privilege be eminently beneficial to science, and consequently to health? Pray turn your attention to this point; and, as you are so capable of taking an enlarged and enlightened view of subjects in general, see if you cannot so unfold my meagre suggestion, as to show at once its justice and reasonableness in such a manner as to secure, if not its adoption, at least the hearty exertions of the profession for ultimately securing it. Being a metropolitan, no advantage would accrue to myself, but my "country cousins" would feel it by the earlier receipt of their mental food.

I am, Sir,

AN INVALID SUBSCRIBER TO THE LANCET.

ROYAL FREE HOSPITAL.—The death, after a few days' illness, is announced of Mr. J. S. Barber, who recently resigned the post of senior dispenser to the Royal Free Hospital, which he had held for the remarkably long period of 59 years. On the occasion of his retirement from active work the committee of the hospital granted Mr. Barber a substantial pension in recognition of his long and faithful service, and the members of the committee and the medical and nursing staff also presented him with testimonials as tokens of their esteem. All connected with the Royal Free Hospital much regret that Mr. Barber has not been spared longer to enjoy his well-earned rest from active work.

THE LANCET.

LONDON: SATURDAY, MAY 28, 1910.

The Toll of the Mine.

ONCE more there has been chronicled a ghastly sacrifice of human life following upon the explosion and firing of a coal-pit. The circumstances of the recent disaster at the Wellington pit at Whitehaven, in Cumberland, are of a more harrowing and distressful kind than any that can be recalled in the previous history of colliery explosions. There were entombed 136 men and boys, to rescue whom appeared impossible, and ultimately the awful duty was imposed upon their comrades of sealing the mine up by means of a brick wall in order to arrest the progress of the fire, and thus to cut off the supply of oxygen necessary as much for human life as for the combustion of fuel. The exact fate of the men who thus perished is still unknown. We can only believe that the end was a merciful one, that agony yielded soon to unconsciousness by the breathing of anæsthetic gases, amongst which carbon monoxide may be fairly reckoned to have been present in overpowering volumes. A serious consideration, and one which in the interest of human life cannot be shirked, is whether this terrible disaster was the result of human error or indifference, or whether it had its origin in circumstances beyond human control. The explosion could not have occurred without its initiatory spark, and whether this was the lighting of a match, the impact of a pick, or some electric leakage will doubtless form the subject of official inquiry; but the best evidence on these points is not available, any witnesses who might have been able to throw a light upon the cause having been silenced for ever. Instances have often illustrated what a disregard, bred of familiarity with an uneventful routine, workmen develop for the terrific potentialities around them, and which may be let loose by a very simple breach of regulations. The neglect to use the nail-brush has poisoned many a worker in the lead industries, and the lighting of a lucifer match in the coal-pit has probably cost many lives. Men do not realise the danger of such proceedings until it is brought home in a dreadful way; too many are apparently oblivious of the regulations which have been drawn up for the protection of their lives and those of their fellows. We welcome, therefore, with particular gladness the reconstitution of the Royal Commission on Mines, which has just been announced, and note with pleasure the strong *personnel* of which it is composed.

Science has done much to minimise the dangers of the mine. Grave questions have received the earnest consideration of the very ablest scientific minds of the country, and sets of rules have been drawn up as a result of these serious studies, the strict observance of which, without the slightest doubt, has averted vast disasters. Science cannot, however, force an absolute regard for the precautions which she indicates, and which are essential in those industries in which lurk potential dangers. But science may go as far as to outline what can be done when, despite every conceivable human effort, the worst, for a mysterious reason, has happened. In this connexion we have in mind the very valuable report of Dr. JOHN HALDANE, to which we drew attention in these columns 14 years ago, on the occasion of its being presented to Parliament, and we are glad to see that Dr. HALDANE is one of the reconstituted Commission. Preventive measures relating to both "gassy" and dusty mines had already received careful consideration, and their practical enforcement was assured as far as anything that is human can be assured. Dr. HALDANE, however, dealt with the case where all preventive measures had failed to bring safety, and deduced from his practical inquiry the kind of methods which should be adopted in order that the loss of life in colliery explosions and fires might be reduced. His suggestions as to the saving of life after colliery explosions and fires have received universal approval, and their observance undoubtedly would reduce the terrors of mine disasters. We should be very glad to be assured, from the evidence that certainly will be demanded by the Royal Commission, that the machinery which is provided for the protection of the miner's life is kept in a rigorously efficient state. We cannot be certain that the suggestions have been adopted universally or backed with real effort, and our feeling on this point is accentuated by reading in the newspaper accounts of the Whitehaven disaster that a rescue party arrived by special train, bringing with them "their smoke helmets and other apparatus for dealing with the gases." From this account, therefore, it would appear that the rescue apparatus was not ready at hand. It would in any case have proved useless in this great subterranean fire, but the circumstances might easily have been such that the immediate availability of life-saving apparatus—smoke helmets and cylinders of oxygen, for example—would have meant all the difference between life and death to many miners.

An interesting observation has been made to the effect that the atmospheric conditions just preceding the day of the explosion presented the same general features as have been observed on the occasions of the majority of the worst mining explosions. During the day, that is to say, the barometer continued to rise, and over the Whitehaven district it reached its highest point (30¼ inches). The question was once asked in our columns, "Are colliery warnings observed?" which, somewhat to our surprise, received an answer from the Press Association, who informed us that colliery warnings were not issued by any Government Department, but by the Press Association. This association had, in fact, supplied warnings as the occasion arose for 24 years. The warnings were first introduced in 1881, when there were no new modern laws, and the result was a diminution in frequency of great colliery disasters, and for many years, said the Press Association, "there has not been a single catastrophe which can be compared with any of the numerous serious calamities of a generation ago, when we so often had to lament the loss of from 100 to 350 men in individual explosions." If the warnings have from the first played a not unimportant

part in the extremely satisfactory progress that has been made in the saving of human life in the mine, the question of the continued observance of these warnings assumes grave importance. We trust that this point will receive consideration when an inquiry into the Whitehaven disaster is opened, a disaster of tragic bulk. As long as man finds it indispensable to his existence to extract potentialities from the earth's great storehouse, so long will he have to face certain risks in adapting these potentialities to his use. But human effort can do much to reduce these risks, and the toll of the mine should grow lighter and not heavier as scientific advance is measured.

The Late King and Medical Work.

BY a habit of our minds we associate national advancement with the names of Kings and Princes. We speak of the Augustan Age, the Elizabethan Age, and the Victorian Age. It is a strange use of words thus to assign a whole epoch to a single life. For we know well that the forces which guide and urge mankind are not in one man, but in all. It took a century of teeming English life to make the Elizabethan Age; neither was that age made by England alone, but by the invention of printing, the discovery of America, and the Renaissance. France and Spain and Italy all lent a hand to shape "the spacious times of great ELIZABETH." Slowly, and in darkness, the forces which make history are formed and gather strength, and at last come into action, controlling and governing the Sovereign and his people. Yet in this custom of naming the world's phases after its Kings and Queens there is more than convention. The Sovereign is more than a mere patron of the arts and sciences. Indeed, men are beginning to be tired of the ordinary talk about Royal patronage. A hundred years ago it was the fashion to have patrons for everything: for a book, a picture, a bit of scientific work. A man could not publish a treatise without a long and high-flown dedication of his writings to this or that member of the nobility; he must describe his patron as the best support and encouragement that any man could ever wish to have. That was the fashion: and at the present time we are well rid of it. The old flattery and subservience are gone, and nobody wants them back. We no longer tell the aristocracy that they are of the utmost value to the arts and sciences: neither do we represent the Sovereign as personally responsible for the intellectual advancement of ourselves.

None the less, he is more than a spectator of the life of his people. For, by the fact that he is KING, all that is in our lives is writ large on his life. We move, each of us, in what we call our set, or our circle; but the set and circle of the KING are his kingdom and his colonies. Our sayings and doings touch a few hundreds or thousands of people, for whom we work; but the sayings and doings of the KING touch all people, for he works for all. We enjoy the loyalty of our colleagues, we maintain the traditions and the honour of our profession; but the KING enjoys the loyalty of his Empire, and maintains the traditions and the honour of our race. Our offences are known to our neighbours, but his offences to the world. Thus magnified, watched, and reported, he is raised above the lines of other men's lives; his example, his way of taking pleasure and of bearing pain, his likes and dislikes, his attitude towards GOD and man, all have a profound influence on the tone and the character of the nation. There was a time when it was believed that the Royal touch healed bodily diseases; and in the body politic the Royal touch works to-day. We still believe, and are justified in believing, that the Sovereign leads the fortunes of his times. Though he does not create the improvement of his people, nor make discoveries in science, nor initiate reforms, nor decide the changing fortunes of Church and State, yet he remains at the head of all advancement, all reform. To him ultimately we do refer and submit our work; and all who work for his people are in a sense working for him. Where have our thoughts been these last few weeks but with the KING? If loyalty to the Throne be not a reality, then what of our lives is real? London with its miles of solid crowd supplied the answer last Friday.

In the service for the burial of the dead KING EDWARD VII. became "this our brother." Well, that is what he had always tried to be. He had kept carefully in touch with all that we were doing; he had always been so keen over our work, so heartily interested in all that was of interest to us, and so quick in sympathy. Neither was it only the quickness of his sympathy that we remember, but its amazing width. He understood everybody, even the rich, who are harder to understand than the poor. He influenced for good the national love of sport; he helped to keep it wholesome and honourable. All sorts and conditions of men, rich and poor, young and old, wise and foolish, are the better for the example of his broad humanity. To us medical men the loss came with special sharpness, for we knew his steady interest in our work. He was always glad to learn how we were getting on; he was, one might say, inquisitive to hear the latest news of our science and our art. That old quotation, *Nihil humani a me alienum puto*, was singularly true of him; with a sort of restless interest in his fellow men he taught himself all that the world was doing; he was able to estimate its hopes and fears, its pleasures, pains, and achievements. And our labour was perhaps that which he chiefly liked and respected. The King's Hospital Fund is but one instance of the help that he gave to our work, for he has shown to our profession many other proofs of his goodwill for us. So far as he could he followed, with careful attention, the development, in the last half-century, of the medical sciences, and their application in practice. No man better understood the uphill strain of the medical man's life, its anxieties and its happiness. In the times of his own illness he was a good patient, brave and hopeful, and bearing pain well, courteous to all about him, and grateful to them. What he thought of our profession's services to himself he said, seven years ago, at the opening of the new buildings of the London Hospital: "I wish to record my deep feeling of gratitude to this hospital, which at the time of my severe illness provided me with so distinguished a surgeon as Sir FREDERICK TREVES, with an anæsthetist in Dr. HEWITT, and with two such nurses, Nurse HAINES and Nurse TARR, whose unceasing attention I cannot sufficiently praise. I declare this building open, and may GOD'S blessing rest on all who come to it for aid and on all who work in it." On his own

work assuredly GOD'S blessing rests; and may it rest in no less abundance on the heavy and incessant work of our present KING.

The Rôle of Comparative Anatomy in Medical Research.

A CENTURY of progress has completely altered the attitude of medical men to the study of comparative anatomy. At the close of the eighteenth century the generation raised under the HUNTERS and the MONROS gave it a chief place in the medical curriculum. At the beginning of the twentieth century we find it given a secondary place; indeed, there are many who would remove it from the medical curriculum altogether. This remarkable change in attitude is not due to fickleness in our medical leaders; it is a result of the revolution which CUVIER, DARWIN, OWEN, and HUXLEY effected in the minds of comparative anatomists. HARVEY, HUNTER, and MONRO were physiologists who used the study of anatomy as the means of ascertaining function, but their pupils and traditions were carried away in that great flood of morphology and evolution which swept the biological world in the nineteenth century, and the study of function sank out of sight. Comparative anatomy, so far as medical men were concerned, was emasculated. Hence the present attitude towards it. But there are distinct signs of a return to the methods and aims of the older anatomists; and we may cite the Hunterian Lectures[1] of Dr. R. H. PARAMORE on "The Evolution of the Pelvic Floor" as an instance. There have been numerous and excellent studies of the musculature of the mammalian pelvis of late years; we may instance the monographs of HOLL, of LARTSCHNEIDER, and of THOMPSON. They are concerned with the exact disposition of the muscles, their development and genetic relations; the part they play in the economy of the animal—the subject most worthy of study—is scarcely noticed. Dr. PARAMORE has made the study of function the first aim of his inquiry. In tracing the rise and development of the pelvic musculature in the various forms of fishes, its modification in amphibians, reptiles, and mammals, his attention is always directed to the life habits of the animals studied; the key to the modifications of the pelvic musculature can be thus obtained. He is able to show conclusively that the levator ani is not, as is now usually taught, a modification of the flexor muscles of the tail, but is, and always has been, part of that ventral sheet of musculature (represented in man by the rectus abdominis) which is concerned in regulating the pressure within the abdomen and in supporting the contents of that cavity.

The problem of the origin of the levator ani is, therefore, in Dr. PARAMORE'S opinion, part of the larger question, What are the origin and function of the musculature of the abdominal parietes? The subject is one which has received much attention of late, particularly in England. Dr. LEONARD HILL has demonstrated the importance of the abdominal musculature in regulating the amount of blood in that cavity; the musculature has a circulatory function. The lectures[2] of Professor A. KEITH served to again direct attention to the part the abdominal muscles play in the mechanism of respiration and in supporting the abdominal viscera. The researches of Dr. HENRY HEAD, Dr. JAMES MACKENZIE, and others, particularly of Professor C. S. SHERRINGTON, have partly revealed to us the complex nerve mechanism which coördinates the action of the parietes of the abdomen with the state of the contained viscera. The importance of such investigations for clinical work cannot be over-estimated. Dr. PARAMORE'S lectures serve to broaden the basis on which our knowledge may be further extended.

The rôle of comparative anatomy in medical research is not to furnish the final evidence of physiological truths; these can be obtained only by observations on living animals in which definite lesions have been established either by design or by disease. Comparative anatomy is suggestive rather than conclusive. The existence of a muscular connexion between the auricles and ventricles in the hearts of the lower vertebrates led to the search for, and discovery of, the auriculo-ventricular bundle in the human heart. Comparative anatomy suggested it as the path for auricular impulses; experiment demonstrated that this was so, and thus the pathology for Stokes-Adams disease was established. A remarkable instance came to our knowlege the other day, leading to the discovery, as yet unpublished, of a new structure in the human brain. The anatomist saw it first in fishes, and following it throughout the animal kingdom learned its existence in the human central nervous system.

It will be observed that Dr. PARAMORE pays particular attention to certain forms of fishes—the Selachian or Shark order and the Dipnoi. At first sight it seems a "far cry" from the dog-fish to man. But thanks largely to the labours of the late FRANCIS BALFOUR, we recognise that the stem from which man has sprung has remarkably close relations with that low vertebrate stock which our humble friend—the dog-fish—has served to perpetuate through long geological periods. The condition of hare-lip and cleft palate is evidently a heritage from the Selachian stock The existence of a representative of the fourth chamber in the human heart was postulated on BALFOUR'S researches on the Selachian embryo; proof of the correctness of the suggestion is furnished by Professor KEITH'S lectures on "Malformations of the Heart."[4] The Dipnoi are also likely to yield most valuable suggestions. Professor G. ELLIOT SMITH[4] found in their brains the commencement of that most characteristic and wonderful of all human structures—the cerebral cortex. The splendid researches of Professor GRAHAM KERR of Glasgow on the development of the Dipnoi will, in course of time, yield results directly applicable to man. Those familiar with the physiological series of specimens in the Museum of the Royal College of Surgeons of England are aware how fully HUNTER had realised that the study of the lower vertebrate forms provided sure keys to the more abstruse problems of human physiology. The official lectures delivered recently before that College by Professor KEITH and Dr. PARAMORE are excellent records of work done on that very line.

Annotations.

"Ne quid nimis."

THE SALARIES OF WHOLE-TIME MEDICAL OFFICERS OF HEALTH.

WHATEVER may be the economical value of health and physical efficiency to the community, a large number of the sanitary authorities in the country seem to assess the services of their official health adviser at such an absurdly low figure that we are led to wonder whether, if the employment of a medical officer of health was not a statutory obligation, certain sanitary authorities would make any such appointment. It seems, in fact, as if some sanitary authorities were so obsessed with the idea of economy that they are quite unable to breathe the atmosphere of sanitary educational advance which is permeating our national social existence of the present time. Otherwise it is difficult to understand how the Walsall town council, which has been nominally appointed to govern a population of about 100,000, can for a moment believe it reasonable or equitable to expect a medical officer of health to carry out his duties as a whole-time officer for the slender income of £400. But not only is this the proposal which is actually being made, but the officer elected, if there are any candidates, will be expected, in addition, to act as police surgeon and as school medical officer, while all fees received by him for post-mortem examinations or for furnishing evidence in law courts are to be paid to the borough fund. Although the stipend is to be raised annually by £25 until £500 per annum has been reached, we can hardly believe that the Local Government Board will be likely to sanction the initial salary, and if the town council adheres to its unfortunate proposal it is to be hoped that the appointment will not receive official recognition. It appears that owing to the illness of the present medical officer of health the council has been content to leave the work largely in the hands of the chief sanitary inspector, which means perhaps that in its opinion questions of preventive medicine rank merely with questions of filth nuisance. The sum suggested would be none too great if offered for the supervision of the medical inspection of the school children of a population such as Walsall has, and we are left to wonder how much it is proposed to give the officers who actually carry out the inspectorial work. Walsall is made up largely of a working-class population of a character which needs constant supervision by the department over which the medical officer of health presides. With the enormous addition of work which devolves upon the health department under the Housing and Town Planning Act as well as under much recent legislation—such as the Midwives Act, and regulations in connexion with the reduction of infantile mortality—it is really quite impossible that the responsibilities can be properly undertaken by an officer who has to defray all his own travelling expenses out of such an inadequate stipend as £400 per annum. We are afraid that the council may not have had the multiple duties of a present-day medical officer of health and school medical officer of a town with 100,000 people explained to it, as otherwise how could such a salary be proposed? The town clerk of Walsall, we believe, is paid £1000 and the gas manager £650. Such a proposition is tantamount to a relative degradation of the status of the public health, and perhaps the Local Government Board and the Board of Education will be able to dissuade the Walsall town council from pursuing its project further. It would be better to keep the office of medical officer of health and school medical officer separate than to amalgamate them in a large town such as Walsall for a total salary of £400. Both these offices should be held by men exercising considerable influence, and this will be rendered impossible under the Walsall proposal.

THE TARNOWSKA TRIAL.

IN a recent discussion on the European State system and its dominating factors a Scandinavian publicist professed to give the following as not only his own opinion but that of many of his compatriots: "The Latin civilisation is effete; the Teutonic has reached its culmination and is now on the descending curve of the parabola; the future belongs to the Slav." To this sweeping generalisation it was objected by another interlocutor that the Slav had taken so kindly to Southern and Western vices that his power of regenerating or rehabilitating his lapsed or lapsing brethren of the south or west was seriously impaired. The Scandinavian replied that the indulgence in these vices was but a passing phase, to disappear under the health-giving, bracing effect of representative institutions, from which the Slav would emerge as a new civilising force, with virtues and, in time, with vices of his own. It was this last admission that gave an opportune turn to the conversation, inspired, as it was, by the strange trial now closed at Venice, in which the protagonist Madame Tarnowska (a Russian lady with an Irish strain in her progeniture) and the two subordinates who "played up to her," Donato Prilukoff and Nicola Naumow, were criminal types, unfamiliar even to Italian or German tribunals, premonitory, moreover, of what the forensic and the law-giving mind may yet have to encounter as new departures to be dealt with when the Slav comes to his own. For wellnigh three months the sombre drama has evolved itself before the assizes at Venice, prosecution and defence, reinforced by the amplest expert opinion, exhausting their resources under a presiding judge of exceptional ability and experience; till at length, after a comprehensive and elaborate summing up, the jury of 12 Venetian citizens has emitted a verdict which seems to have satisfied no one—least of all the "man in the street"—whose hisses and howls of indignation were audible even by the convicted trio as they passed from the dock to the cells. It is impossible to recapitulate here the long, the complicated, story which has dragged its slow length through the journals, Italian and Continental, for the space of 12 weeks. Suffice it to state that in Madame Tarnowska has been revealed a character in some respects quite novel in the annals of crime—a woman in whom sensual instincts of the most imperious and compelling force co-existed with a cool, calculating judgment which acknowledged seemingly every restraint, except that of conscience. "La donna fatale," as the Italian press denominates her, combined with the impulsive pleasure-seeking of a Cleopatra the stern purpose and the remorseless energy of a Clytemnestra or a Lady Macbeth, bending to her will an able, circumspect, and prosperous barrister like Prilukoff till, from sheer devotion to her, he abandoned wife, household, and career to become her tool, and not only her tool, but her sympathising assessor in her schemes for money-making and sensual indulgence, almost equalling herself in fertility of expedient and clandestine device for the gratification of both. Coöperating with her in her plan to get rid of her husband, seemingly a kindly, weak man, he had to see himself practically superseded by another infatuated devotee in her service, the youth Naumow, over whom she yielded such a spell that we find him prepared not only to be the assassin (which he actually came to be) of his dear friend her husband, but pledging himself to commit suicide if, by so doing, he could protect her in any way or baffle the retributive justice she dreaded. It is in the slavish response of

these two—Prilukoff and Naumow—to her imperious, if often-shifting, methods that much of the interest in the drama centres—a response that exercised the resources of the eminent psychiatrists retained for their defence in endeavouring to account for it. Both, particularly Naumow, were addicted to powerful sedatives and stimulants, alternately antagonising each other, their effects impairing the resisting force of either victim to that yet more subtle and coercing "sedative *cum* stimulant" embodied in Madame Tarnowska herself, who, even at a distance of many days' journey, could by the telegraph or the telephone, command their presence or their coöperation at whatever the self-sacrifice imposed on them. Playing the part of a Circe or (by proxy) a Clytemnestra, she could be as overwhelmingly seductive as the one or as *ἀνδρόβουλος* (man-minded, to quote the Æschylean epithet) as the other, till she made the astute barrister an accomplice in the assassination effected by the cultured youth on his friend her husband—both barrister and youth, moreover, being ready to "get rid of each other" by any means if only to secure the chief place in her affections. In her case, as in theirs, the experts in psychiatry left no argument untried to minimise "responsibility," and the vocabulary of their *métier*, when the official report of the *cause célèbre* is published, will be found to have added to its resources a terminology which would have proved strange to the arch-priest of psycho-criminology, Cesare Lombroso himself. That report must see the light before a scientific appreciation of the pleading *pro et contra* is practicable. Meanwhile the verdict which condemns Prilukoff to ten years' imprisonment, Madame Tarnowska to eight years and three months, and Naumow to three years is accepted as "provisional" merely, till the Court of Cassation, to which the trio have appealed, retraverses the whole evidence. But pending that Court's decision the Italian press, with few exceptions, is convinced of the inadequacy of the punishment, quoting the well-known exclamation of its Dean, Antonio Gallenga, when a "belva umana" (human wild beast) escaped the penalty of the coolest and most atrocious of murders with a limited term of imprisonment: "Accursed be the man who invented 'attenuating circumstances.'"

THE TRAINING OF NURSEMAIDS.

THE Women's Industrial Council has for some time past been endeavouring to induce public bodies to adopt a scheme of training working-class girls as nurses for children. With the object of affording a practical demonstration of a scheme for this purpose it is proposed to rent a house which will be opened as a day-nursery for the children of mothers who are obliged to go out to work, and this nursery will be used for the training of working-class girls in the proper care of children. The girls will live in the house, and in addition to their training in infant management under the matron, will receive practical teaching in housework, cookery, laundry-work, needlework, and so forth, under a trained domestic economy teacher. It is also proposed to include in the scheme "infant consultations" for those mothers who are able to look after their own babies, and an evening club for working girls of the neighbourhood. It is, of course, recognised that such a home cannot be entirely self-supporting, and it is estimated that the initial expenses of fitting up and furnishing a house with accommodation for 20 girls and their teachers will necessitate an expenditure of £1000. It is to be hoped that the scheme will not be allowed to fail from lack of financial support, and we are glad to notice that it has already received the approval of many men and women interested in reforms which have for their object the social welfare. On Monday, June 6th, at 5 P.M., a drawing-room meeting will be held at 25, Cavendish-square, London, W., by the kind permission of Lady Horsley, when the objects of a crèche which the Women's Industrial Council is starting at Hackney will be explained. On June 2nd Miss Evelyn March Phillips will deliver a lecture on "Old Italian Villa Gardens," with lantern illustrations, at the house of Lord and Lady Brassey, 24, Park Lane, at 8.30 P.M., in aid of the funds for the crèche. Apart from the undoubted benefit to the community as a whole which would result from the active operation of a scheme of this kind, the individual benefit to the girls themselves in fostering the domestic instinct and love of children, which are too often starved owing to modern industrial conditions, should also be great. Further particulars can be obtained from the secretary to the council, 7, John-street, Adelphi, London, W.C.

THE EYE OF THE SCALLOP.

A LONG and interesting article by the demonstrator of zoology in Belfast, Mr. W. J. Dakin, on the Eye of the Pecten Jacobæus or Scallop, appears in the last number of the *Quarterly Journal of Microscopical Science*, in which we see Nature making an early essay, trying her 'prentice hand in a bivalve mollusc at the greatly perfected eye of the mammal. Mr. Dakin's researches were pursued at Naples and also at the Port Erin biological station. He used, and gives the composition of, a great variety of staining fluids. The eyes of Pecten occur on the free border of the middle fold of the mantle edge of both valves; a larger number are present on the upper mantle lobe—that is, more on the left valve than on the right, the left valve being the uppermost. The eyes vary in size. Anomalies are not uncommon, as, for example, the fusion of two eyes and defective pigmentation. Each eye has a short stalk, and appears, as Poli pointed out, to be a modified tentacle. The stalk is composed of connective tissue and is covered by an epithelial layer, both continuous with that of the mouth. A few unstriated muscular fibres permit slight movements to be made, which are in strong contrast with the free movement of the tentacles. In addition the stalk contains blood-vessels and a nerve. At the end of the modified tentacle the stalk swells slightly and is occupied by the optic vesicle. The surface of the swelling is covered by a pigment mantle composed of pigmented columnar epithelium, which is replaced by unpigmented columnar epithelium over an area corresponding to the cornea. The cells of the cornea rest upon a pellucid, finely laminated true cornea. Immediately behind, and in contact with the posterior surface of the pellucid cornea-like structure, is the circular biconvex lens, of which the distal surface is nearly flat. The space in which the lens is suspended is bounded in the fore part by the connective tissue wall of the optic vesicle, the subcorneal layer of the same, and behind by the septum, which is a connective tissue membrane separating the dioptric part of the eye from the retina. The lens is composed of cells of irregular form and variable size, usually flattened near the surface, elsewhere often pyriform with a long process. The retina covers half the interior of the optic vesicle. It is made up of two layers of recipient cells innervated by two branches of an optic nerve, an anterior layer of distal sense cells having each a comblike margin with their interstitial supporting cells, and an inner layer of rod cells and their continuations, the rods also having interstitial supporting cells and an axial neuro-fibril. The distal surface of the retina is bounded by a single layer of cells, the distal sense cells, the outer ends of which are directed towards the septum, and are broad and bear ciliа-like processes, so that a space exists between septum and cell layer, which is crossed by the nerve fibres from the

distal nerve, and filled by the processes of the cylindrical distal cells; their lower ends are rounded and in some instances appear to end in a short-pointed process. The cell contents are finely granular. Between the cells pass branches of the distal nerve, which can be traced with care through the septum, but with difficulty beyond; they probably terminate in the cells, not by becoming continuous with the cilia-like process, but as an axial fibril running towards the base. The rod cells lie in a matrix of tissue containing oil globules. The retina also possesses bipolar nerve cells which are interstitial supporting cells. Below the rod matrix which underlies the rods is a limiting basement membrane. Beneath the retinal layers is the tapetum, consisting of polyhedral cells reflecting a silvery light. Finally, there is a pigment layer corresponding in position to the choroid. The retina is innervated by two branches of an optic nerve which passes down the centre of the eye stalk and arises from the visceral ganglion. The retina of pecten is of the inverted type, like that of the vertebrate eye, the recipient bodies or rods being directed away from the light. The retina is made up of two series of recipient cells innervated by two branches of an optic nerve, an outer layer of distal sense cells, and an inner layer of rod cells; both layers possess interstitial supporting cells. The illustrations show the optic nerve dividing near the capsule into two branches, one of which continues its course to the sclerotic, whilst the other passes to a point midway between the cornea and the back of the capsule, then penetrates the capsule, and, running in front of the retina, gradually thins out by giving off branches which enter the retina and terminate in the anterior sense cells and the posterior layer of rods. It is curious to see so highly organised a structure in one of the lamellibranchs.

HOSPITALS IN SHIPS AT SEA.

THERE has reached us, in the reports of the International Medical Congress[1] held at Budapest, a very interesting paper on the Hospital Establishment of Passenger Ships by Dr. Dupuy and Dr. Villejean, who know their subject, as they have both been to sea in the French Emigration Service. They give us excellent plans of the hospital establishments on board French ships of all kinds, from the sailing schooner *Notre Dame du Salut*, hospital ship for the fishermen of St. Pierre and Newfoundland, to the *Loire*, with her large accommodation for sick convicts, and the extensive range of hospital cabins in the new ships *La France* and *La Plata*. The writers note and lament that the French law demands fewer beds than do the laws of other nations, but in view of the efforts made and being made by shipowners, this is no time for despair. In their latest plan, that of the hospitals in *La Plata*, one of a group of four new ships, we find 20 beds for women, 22 for men, besides an isolation hospital with 10 beds for men and 8 for women—all on the upper deck, and apparently at the fore-end of the superstructure, while on the deck above the medical officer has his consulting-room which in emergency can be used for an operating-room. Besides all this, most recent French ships seem to have one or two cabins for lunatics. It would be a pity to press just now, as the authors desire, for an increase of the beds required to be provided from 2½ to 6 for each hundred of passengers and crew, especially when shipowners are paying more attention to sanitation, and illness at sea is decreasing, as shown by the statistics of our own and other navies. It would be better to utilise the money which more beds would cost for purposes of sanitation and endeavour to keep the passengers from using even the existing beds. Dr. Dupuy and Dr. Villejean have made a thorough and most careful study of the whole question, as is shown by the tale of the improvements they desire, including a special operating-room, a mortuary, also to serve as post-mortem room, and a bacteriological laboratory. This last need, we may say, is met in Germany by a recent order that every passenger ship going abroad shall carry a microscope and a bacteriological equipment. These are contained in a nickelled box, some 18 × 12 × 9 inches, and besides the microscope and the slides there are enclosed stains, tubes of media, capillary and other glass tubes, and so on. We are thoroughly in accord with the authors in their desire for a steam disinfector on board every ship, and for better lodging for the hospital attendants than they usually get; and we are much obliged to them for telling us how great are the advances recently made in the French Mercantile Marine.

[1] Section XXI., 2me Fascicule at pp. xiv. and 212.

A SIMPLE TEST FOR BLEACHED FLOUR.

THE bleaching of flour by chemical oxidising agents has been condemned by more than one physiological authority on the ground that the process interferes with the nutritive value of the protein. The public in its silly and ignorant craving for a spotlessly white loaf encourages the practice. The intelligent man will not regard the whiteness of the loaf as an evidence of its purity. Fortunately, it is within the power of all to apply a simple test for flour that has been bleached. Wheaten flour possesses a natural yellow colouring matter which is soluble in petrol and therefore if a little unbleached flour is shaken up with petrol it imparts to the spirit a yellow colour. Bleached flour similarly treated leaves the spirit quite white. About half an ounce of flour shaken with two fluid ounces of petrol suffices. The test should, of course, be conducted away from any flame, since petrol is highly inflammable.

ACUTE PULMONARY ŒDEMA AS A TERMINAL EVENT IN EPILEPSY.

ACUTE pulmonary œdema has not received much attention until recently and is unmentioned in many text-books. In the *American Journal of Medical Sciences* for March Dr. A. P. Ohlmacher reported five cases in which it was a terminal event in epilepsy. It occurred under various conditions—accompanying a single major fit and soon followed by death; after a single attack with death at a longer interval; after series of fits not reaching the status epilepticus, and hastening the status epilepticus to a fatal termination. Dr. Ohlmacher suggests that in the not uncommon cases in which epileptics are found dead in bed death is due to pulmonary œdema after one or more fits rather than to mechanical asphyxia by the bed-clothes, as is commonly believed. The following are two of his cases. A female, aged 19 years, was admitted into the Ohio Hospital for Epileptics in 1896. She had suffered from fits since the age of 17 years. There were seldom more than one or two fits in the 24 hours, but a month rarely passed without a major attack. She was sane and above the average epileptic in intelligence, and her general health was good. On April 8th, 1899, she went to bed in her usual health at 8 P.M. Half an hour later a major attack occurred. When seen soon after the fit began she lay unconscious on her back; the breathing was loud and stertorous; a thin foamy fluid escaped from her mouth and nose. At times the fluid was pinkish, and when she was turned on her side a gush amounting to about two ounces would follow. The respirations were from 16 to 20 and coarse râles were audible at a distance from the chest. The skin was cold and clammy and the pulse was of good volume and only slightly accelerated. The breathing became short and gasping and death took place at 10 P.M., 1½ hours after a single epileptic attack. At the necropsy large gushes of frothy fluid escaped

from the mouth whenever the body was moved. The lungs were waterlogged and bubbly serum flowed from them when they were incised. The thymus, lymphatic glands, and spleen were enlarged. In another case, a man, aged 22 years, the subject of grand mal and incipient epileptic dementia, while in his usual health, after eating a hearty supper, had a fit and fell forcibly on his head. He did not breathe properly after the convulsive phase of the attack, and when seen by the resident physician there was urgent dyspnœa with frothy fluid escaping from the mouth. The breathing became more laboured and death occurred 20 minutes after the attack. At the necropsy foamy blood-stained fluid gushed from the mouth and nose when pressure was applied to the chest. The lungs weighed as much as 2170 grammes, and on section showed reddish, œdematous infiltration. The thymus, tonsils, lymphatic glands, and spleen were enlarged. In all the five cases similar changes to those described were found at the necropsy, and there was neither renal nor cardiac disease. Dr. Ohlmacher concludes that acute pulmonary œdema occurs in epilepsy which is associated with the status lymphaticus. As to the frequency of acute pulmonary œdema in epilepsy, the statistics of the Ohio Hospital show that in 1903–05 203 epileptics died. In 41 cases death followed a single epileptic attack or was otherwise sudden; for example, the patient was found dead in bed. Of these 41 cases œdema of the lungs was found in 13. In the same period 41 patients succumbed to the status epilepticus, and œdema of the lungs was found in 15.

THE SALE OF POISONS.

THE administration of the penal clauses of the Pharmacy Acts is one of the most important duties of the Pharmaceutical Society, and at the society's sixty-ninth annual meeting some interesting details of the work which the carrying out of this duty entails were given. Last year the council investigated 1360 cases of alleged infringements of the Acts, but in only 155 instances was it found necessary to institute legal proceedings. In the vast majority of these cases the offences consisted of the sale of poisons by unqualified persons or the keeping open shop for the sale of poisons, while in a few cases the offence was the non-observance of the formalities which the law requires to be fulfilled in selling poisons. With very few exceptions the society was successful in recovering a penalty of £5 from each offender. The society's law costs last year amounted to £835 6*s*. 10*d*., an increase of no less than £500 on the previous year, and as the President remarked in his address to the members, this expenditure is very satisfactory from one point of view, but very unsatisfactory from another. On the one hand, it points to an endeavour by the council to administer with reasonable vigour the statutes relating to the sale of poisons and the conduct of chemists' shops. "On the other hand," said the President, "it scarcely seems fitting to make the members of the society bear the whole cost of fulfilling this valuable public duty. The 1360 cases taken up last year were equivalent to so many arrests of public dangers, yet for this police duty the general community, and a large minority of the pharmaceutical body, contribute nothing." During the year the society was unsuccessful in an important appeal case, the High Court deciding that it is not illegal for an unqualified person to call his place of business a "pharmacy," notwithstanding that it is an offence for such a person to call himself a "pharmacist." Referring to this decision the President said that the position in regard to the use of place names which are mere variants of professional titles could not be permitted to remain as it is, and he intimated that it was the intention of the council to take steps to secure, if possible, the removal of the anomaly. After the administration of the law relating to the sale of poisons, the next most important duty of the society is the conducting of the pharmaceutical examinations. The two functions are, in fact, closely related, for the main purpose of the examinations is to ensure that persons who keep open shop for the sale of poisons shall be qualified by training to be entrusted with the handling of potent drugs. Some idea of the searching character of the qualifying examination may be obtained from the fact that of 1060 candidates who were examined last year only 397, or barely 38 per cent., were successful. The large percentage of failures is due, to an appreciable extent, to deficiency in training. The remedy for this is to make it essential that every candidate before being allowed to enter for the examination should have undergone a recognised systematic course of instruction in the subjects in which he is examined. Until the coming into force of the new Poisons and Pharmacy Act on April 1st last year the council, however, had no power to enforce the training of candidates, but that Act empowered the society to make by-laws: (1) requiring persons desirous of presenting themselves for examination to produce satisfactory evidence that they had received a sufficient preliminary practical training in the subjects; and (2) providing for periods of time and courses of study in connexion with the qualifying examination, and dividing such examination into two parts. According to the annual report, which was adopted at the society's last meeting, the council now has under consideration the formulation of such by-laws. The board of examiners has been asked to advise as to the establishment of a compulsory course of systematic training, and the report will be referred to a special committee, which will probably deem it advisable to take into consultation those engaged in the teaching of pharmacy. Another way in which the new Act empowers the society to make better provision for ensuring that the sale of poisons shall be under more efficient control is by requiring that in every shop kept open for the sale of poisons the certificate of the qualified person in charge shall be conspicuously displayed. Last year 4244 shops were inspected with the view of ascertaining whether the law in this respect was being obeyed, and in a small proportion of instances only was it found that the requirements of the new Act were not complied with. A year's experience of the working of the new regulations seems to show that the sale of poisons is now capable of being placed under better control than was formerly the case.

THE PART PLAYED BY NON-TUBERCULOUS MEAT IN THE DIFFUSION OF TUBERCULOSIS.

THE danger of contracting tuberculosis from consuming the flesh of a tuberculous animal is now well recognised. At a meeting of the Académie de Médecine of Paris on April 5th, M. G. Linossier and M. G. H. Lemoine showed that similar danger may arise from consumption of the infected flesh of non-tuberculous animals—a fact which has not previously received attention. In investigating the effect on the kidneys of guinea-pigs of the subcutaneous injection of macerated beef they were surprised at the number of the animals which died from tuberculosis. Nothing similar occurred among animals which were given subcutaneous injections of serum, milk, or white of egg. The beef used was bought in good shops and had been submitted to veterinary inspection at the abattoirs. It certainly was not tuberculous. The conclusion was that it must have been accidentally contaminated. The researches of Decker show that there is great diffusion of tubercle bacilli at the abattoirs.

Of 13 butchers' knives he found that 10 were contaminated with tubercle bacilli and of 9 inspectors' knives 3. On the ground and the walls of the slaughtering rooms the bacilli were found in 6 out of 25 experiments. Evidently the beef used in the injections had been contaminated at the abattoir by contact with the knives or hands of the butchers, the ground, or even with organs condemned as tuberculous by the inspectors. In order to verify this hypothesis a piece of rib beef and a piece of sirloin were taken from animals affected with pulmonary tuberculosis. Here the chances of contamination of the healthy muscles with tuberculous matter in cutting up the carcass would be great, and if this occurred the bacilli ought to be found only on the surface of the meat. This was found to be so. 16 guinea-pigs were inoculated with macerated portions taken from the surface of the two pieces of meat. 11 died from tuberculosis in from six weeks to two months. The remaining five died within eight days from an intoxication which was found to follow not only injections made from meat but from all animal foods such as eggs, milk, &c. Six guinea-pigs were inoculated from the central part of the meat. Four died within eight days and none died from tuberculosis. Finally, 16 guinea-pigs were inoculated with the same meat after it had been placed in an oven at a temperature of 180° C. sufficiently long to cook it to a depth of 3 millimetres. None died from tuberculosis. It follows that even slight cooking prevents any danger of contracting tuberculosis from sound meat, but the danger exists if meat is consumed raw, as it sometimes is for therapeutic purposes. M. Linossier and M. Lemoine suggest that measures should be taken in abattoirs to prevent all contact, direct or mediate, between sound meat and tuberculous organs.

THE ROYAL COMMISSION ON MINES.

THE announcement that the King, on the recommendation of the Secretary of State for the Home Department, has approved of the reconstitution of the Royal Commission on Mines, for the purpose of inquiring into the health and safety of persons employed in metalliferous mines and quarries, will be received with general approval. We may be sure that the question of rescue apparatus will occupy much of the attention of the Commission. The new Commission will be composed as follows: Sir Henry Hardinge Cunynghame, K.C.B., Vice-President of the Institute of Engineers and Assistant Under-Secretary to the Home Office (chairman); Mr. R. A. S. Redmayne, F.R.S., Chief Inspector of Mines; Dr. J. S. Haldane, F.R.S.; Mr. John S. Ainsworth, M.P.; Mr. R. M. Greaves; Mr. R. A. Thomas, general manager of the Dolcoath Mine, Cornwall; Mr. R. T. Jones, secretary of the North Wales Quarrymen's Union; Mr. William Lewney, secretary of the Furness Iron Ore Miners' and Quarrymen's Union; and Mr. U. Lovett, secretary of the National Union of Quarrymen. Mr. T. E. Bettany and Mr. G. W. Chrystal will act as joint secretaries of the Commission.

WE understand that Sir Thomas Barlow, President of the Royal College of Physicians of London, has been nominated by the selection committee to be the President of the International Medical Congress, which meets in London in 1913. Dr. W. P. Herringham has been nominated to be the General Secretary. The nominations will go before the general committee for confirmation.

Mr. J. Herbert Parsons, D.Sc., F.R.C.S. Eng., will deliver an address on Some Effects of Bright Light upon the Eyes, at the meeting of the Ophthalmic Section of the American Medical Association at St. Louis, Mo., on Wednesday, June 8th.

Mr. D'Arcy Power has been elected a corresponding member of the Budapest Royal Society of Medicine, the oldest scientific body in Hungary, in recognition of his services as honorary secretary of the National Committee for Great Britain and Ireland of the Sixteenth International Medical Congress.

MOTORING NOTES.

BY C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

Wind Shields and Wet Weather.

GLASS wind screens are immensely convenient, but though few care to dispense with them they have disadvantages, and, of course, if an accident occurs they may form an added danger. A common trouble is clouding in wet or cold weather, and to obviate this inconvenience the folding wind screen has been introduced. Practically it is impossible to drive with the front glass fully up in wet weather, and the usual divided screen when the top half is down gives very little protection against rain. The "Pioneer" is a divided screen, the top glass of which is automatically raised by telescopic tubes fitted with springs and regulated to the required line of vision by thumb screws, which can be set at such an angle that the vision is not impeded, while the occupants of the front seats are protected. Messrs. Lowe, Bevan, and Co., of Birmingham, who are the inventors of this device, also manufacture the "Kenilworth" and the "Perfection" screens, which also provide fair protection without view obstruction to the other passengers. Messrs. Auster of Birmingham, Messrs. Morgan and Co., Limited, of 10, Old Bond-street, London, and the Gordon Carriage Works of Peckham, among others, turn out excellent divided screens, the feature of which is that the bottom half can be regulated at any angle required, and the upper part fixed in an upright position or angled towards the steering wheel. Another pattern provides an oval opening in the upper half, which is exactly in the line of the driver's vision. On some straight shields a sort of squegee is fitted, and by means of an easily reached handle the glass can be cleaned if it becomes cloudy. Moistening the glass with glycerine, or painting on a mixture of equal parts of alcohol and glycerine, or wiping with a cloth dipped in paraffin all serve to maintain clearness and transparency, as most chauffeurs know.

Some Points on Hoods.

On cars with the Cromwell type of screen it is well to specify when ordering a Cape-cart hood that a "five stick" should be supplied. Otherwise the makers fit on the ordinary four-stick pattern, and with these hoods the fore support projects across the entrance to the front seats, and then the driver will discover that entrance and exit from the front seat needs a certain acrobatic skill and is not a dignified proceeding. The five-stick hood allows ample room. The usual material for a Cape-cart hood is a double layer of a kind of drill, and between the two a sheet of fine mackintosh is generally placed. This material looks well, but if the hood if frequently lowered the inner mackintosh is apt to crack, and then at that part it is no longer waterproof. A much better wearing substance is a chemically treated canvas, this is thicker, does not crack, and is always rainproof. Leather hoods, like those on horse-drawn vehicles, need attention if cracking is to be prevented. Most saddlers keep a special preparation which, if occasionally rubbed in, will obviate fissures.

A Simple Pocket Tyre-tester.

The care of the tyres is an important point, and there can be no doubt that correct inflation of tyres does more than anything else to prolong the lives of these expensive articles. Most tyre gauges are expensive and somewhat cumbersome, and many motorists will welcome the Twitchell tyre-tester, for which Messrs. Brown Brothers, Limited, of Great Eastern-street, London, have taken over the agency for the United Kingdom. The device consists of a small cylinder, at one end of which is a pin for depressing the plunger of the tyre which is to be tested; at the other extremity is a rod on which is marked the pressure in pounds; the air in the

tyre blows out this piston, which thus shows the pressure in the tube in pounds. The instrument is so small that it can be carried in the waistcoat pocket; it is accurate, simple, cannot get out of order, and can be applied in two seconds. I believe that many large motor companies are very favourably disposed towards its use.

The Budget.

The Finance Bill in its last shape contains none of the changes which seem to have been expected in some quarters regarding motors. It enacts that the medical profession shall pay, for cars used for professional use, 1 guinea if the horse-power be under 6½, 1½ guineas if under 12 horse-power, 2 guineas if under 16 horse-power. The only addition is that licences taken out for the year are to cease to have effect on June 30th, and that new ones will have to be taken out on July 1st, but allowance will be made for any duty paid for any period prior to July 1st.

THE LATE KING EDWARD VII.

MANY tributes to the memory of the late King Edward VII. and addresses of condolence with the Queen-Mother and King George V. have been paid during the last week by medical bodies and institutions, in addition to those which we have already recorded or which are mentioned by our correspondents.

At the meeting of the General Medical Council on May 24th, on a motion from the chair, the members all standing, it was agreed unanimously that a humble address to the King should be adopted by the Council and transmitted through the Secretary of State for the Home Department. The sympathy of the Council in the sudden grief which has fallen upon the Royal House and all subjects of the Crown was expressed in the opening sentences of the President's Address, and will, in response to a motion which was carried by acclamation, be printed in the minutes of the Council.

The Royal Colleges of Physicians and of Surgeons, Ireland, have both adopted addresses of condolence with King George and the Queen-Mother.

At an extraordinary meeting of the Royal College of Physicians of Edinburgh held on May 12th Dr. W. Allan Jamieson, the President, proposed the two following addresses, which were unanimously agreed to by the Fellows, upstanding:—

To the King's Most Excellent Majesty.

MAY IT PLEASE YOUR MAJESTY,—We, the President and Fellows of the Royal College of Physicians of Edinburgh, humbly approach Your Majesty to express our profound sympathy in the great bereavement which has been suffered by Your Majesty, Your Royal Consort, the Queen Mother, and the other Members of the Royal Family in the death of our much beloved Sovereign, King Edward.

With the nation at large we mourn the loss of one whose life was so conspicuously devoted to the maintenance of peace, not only witbin the confines of the Empire over which he ruled, but throughout the world.

This influence was achieved in great measure by his unfailing tact, his accurate knowledge of mankind, his geniality of disposition, his gift of recollection and recognition of individuals, and his conspicuous devotion to the discharge of every duty.

To us as members of the medical profession King Edward's active interest in the health of his subjects comes specially home. The influence of his work, as Prince of Wales, on behalf of the London hospitals was felt far beyond London, while the great interest he took in the subjects of cancer and consumption will, we believe, yield abundant fruit in the future.

We most loyally and heartily congratulate your Majesty on your accession to the Throne, and we confidently anticipate that your wide experience of travel and consequent familiarity with all parts of your dominions and their inhabitants will specially appeal to a nation which loves a sailor king.

We hail with satisfaction your love for the country, for field sports, and for quiet domesticity, as a means of directing the trend of thought towards that simpler existence and plainer life on which we, as medical men, lay so much stress.

In assuring your Majesty of our most loyal and dutiful allegiance we warmly express the hope that with your Gracious Queen Consort you may long be spared to reign over a happy and prosperous empire.

Signed in name and under the seal of the Royal College of Physicians of Edinburgh this the Twelfth day of May, One thousand nine hundred and ten year.

Unto Her Majesty Queen Alexandra.

MAY IT PLEASE YOUR MAJESTY,—We, the President, Vice-Presidents and Fellows of the Royal College of Physicians of Edinburgh, desire to convey to Your Majesty our truest sympathy in the sad and unlooked-for bereavement Your Majesty has sustained. We rejoice in the thought that King Edward was spared acute pain or prolonged and exhausting suffering, and that Almighty God so tenderly took him into His keeping. Your Majesty's address has touched every heart, and we are sure that your wishes therein expressed will be most faithfully and loyally obeyed. It is our earnest hope that Your Majesty may be long spared to a peaceful and much-honoured life among a devoted people.

An eminently practical way of showing honour to the memory of King Edward VII. was that adopted by the chairman and governors of St. George's Hospital, of which the late King was patron. Having in respectful and grateful remembrance the interest which his late Majesty, as founder of the King's Hospital Fund and as patron of a hundred and more hospitals, was pleased to take in all medical charities throughout his kingdom, they decided "as a slight and humble token of respect to the late King and to mark their loyal sympathy with His Gracious Majesty the King," to invite representatives of the larger voluntary London hospitals to be present at Hyde Park Corner during the procession, and for the memorial service in the hospital chapel.

At an extraordinary meeting of the Court of Governors of Middlesex Hospital held on May 13th, under the presidency of the Duke of Northumberland, an address to the King was unanimously passed which contained a reference to the fact that it was largely due to the sympathy and interest which King Edward VII. displayed in every effort made for the alleviation of suffering and the encouragement of scientific research that the Middlesex Hospital cancer charity was established upon its present basis. An address to the Queen-Mother was also adopted at the same meeting.

At a meeting of the board of the Royal Free Hospital held on May 13th, of which his late Majesty was patron, Major Ricardo, the chairman, referred to the great loss which had been sustained by the death of His Majesty King Edward VII., and moved that an address be presented to the King and also to the Queen-Mother.

At an adjourned general meeting of the members of the Royal Institution held on May 23rd, Sir James Crichton-Browne, treasurer and Vice-President, in the chair, a resolution of condolence on the lamented death of his Majesty King Edward VII., the patron of the Royal Institution, was passed unanimously.

The Council of the Royal Sanitary Institute has presented to the King an address on behalf of the members of the Institute, "humbly expressing profound sorrow for the grievous loss which His Majesty and his subjects have sustained by the death of King Edward VII." The address refers to the interest which was always shown by His late Majesty in the physical and social welfare of his subjects.

On May 25th the Royal Meteorological Society adopted an address of condolence and homage for presentation to the King.

At a meeting of the Reading Pathological Society, held at the Royal Berksbire Hospital on May 12th, a resolution which will be sent to the King was unanimously passed. It is a curious coincidence that the Reading Pathological Society was founded in the same year that His late Majesty King Edward VII. was born—viz., 1841.

MEDICINE AND THE LAW.

Browne v. *Honan and Others.*

AN action recently heard by Mr. Justice Jelf and a common jury illustrates the difficulties with which relatives and friends have to contend in cases of mental trouble which do not go beyond the "borderland," but in which they are driven by circumstances to interfere. The plaintiff sued Mr. Honan and two other defendants, keeping a nursing home, for damages for alleged false imprisonment. He had gone to the office of the defendant Honan and complained that he thought he was going mad, and through the intervention and assistance of Honan, who was far from being on intimate terms with him, was placed in a nursing home kept by the other defendants. He was not certified as insane and was not detained by any compulsion in the home, for after being there for a short time he left and went to his flat, afterwards returning to the home, where he had voluntarily made a payment of £6 6*s.* for his own maintenance. In the witness-box he made allegations of hypnotism having been practised on him, but his counsel, at the conclusion of his examination, withdrew the case so far as it concerned the keepers of the nursing home and offered no further evidence. After Mr. Honan had given

evidence denying the charge of hypnotism the jury agreed with the judge that the case should be ended, and found a verdict for the defendants, in whose favour judgment was accordingly given.

Registration of a Death due to a Cause Unknown.

Attention has been called recently to the death of a schoolboy in whose case a medical man was called in after he had been ill for some time and who did not then apparently have time to examine and prescribe. At all events, the gentleman in question, on his return a few hours later, found the patient dead and certified as to the cause of death as follows: "Not known; pneumothorax ten hours; heart failure." Upon this certificate the death was registered without the coroner being communicated with, and the body was buried. It certainly seems strange that a death the cause of which was "unknown" to the medical man who attended the case should have been registered, and, as our contemporary, *Truth*, suggests, further inquiry would be desirable. The registrar was unfortunate in overlooking, as perhaps he did, the word "unknown," and was misled by the form of a certificate intended to express ignorance as to the cause of the symptoms mentioned, but medical practitioners may be reminded that it is open to them to refuse to give a certificate and to leave the coroner to inquire the nature of the case and the cause of refusal.

Falsely Pretending to be a Registered Medical Practitioner.

At the North London police-court recently a man named Henry Werner was prosecuted by the Medical Defence Union for falsely pretending that he was a registered medical practitioner. An unusual feature in the case consisted in the fact that Werner not only attended a man who had taken poison, but after his death gave evidence at the inquest which followed, and when questioned by the coroner replied that he was a registered medical practitioner. At the close of the inquest he signed the expense sheet and received the usual guinea fee of a medical witness. The Medical Defence Union, whose secretary, Dr. A. G. Bateman, noticed the case in the paper, sent one of its officials to call at the address given, and this gentleman asked for "Dr." Werner, who prescribed for him and charged him 5*s.* for so doing. It was further stated that an advertisement appearing in the *Pelican* described the defendant as "Dr. Werner, the celebrated French Specialist." Whatever may be implied by the description "a French Specialist," the defendant does not appear to have alleged any foreign qualification to practise medicine, but only stated through his advocate that he had had "considerable experience on the Continent," and that he thought he was entitled to practise as a medical man in England. It may be observed with regard to such cases that experience on the Continent is not likely to suggest to anyone that foreigners are entitled to practise medicine at will in countries the qualifications of which they do not possess. Mr. Hedderwick, the magistrate who heard the case, called attention to its serious nature and inflicted a fine of £20 with £5 5*s.* costs. The penalty does not appear to be the heaviest to which the acts of the defendant laid him open, but it may serve as a warning to others, and the Medical Defence Union is to be congratulated on the issue, although the thought may occur that a case in which there has been loss of life, and in which an untrue reply has beyond contradiction been made to a coroner as to the essential qualification of a witness, merits the attention and care of the Treasury, instead of which it has been left to a private agency to bring the delinquent to justice.

The Question of Responsibility for Medical Attendance.

At the Liskeard (Cornwall) county court recently Messrs. Hingston, Carter, and Pearse, surgeons, of Liskeard, claimed £14 13*s.* from Mr. H. Scharien of Mayfield, Sussex, for professional attendance upon his daughter. Evidence showed that Miss Scharien, who was staying at Morvah, became ill, and the landlady wrote to the defendant asking if she could call in a medical man, and he instructed her to do so. For the defence it was contended that Mr. Scharien was not liable for his daughter, who was 35 years of age, and he also denied that he had written to the landlady telling her to get medical attention for his daughter. His honour, Judge Granger, K.C., said this was a case which ought to be taken notice of in Cornwall. Numerous invalids were sent there, and care should be taken that persons who sent invalids should give an authority for obtaining medical attendance. His honour added that evidence showed that the defendant had instructed the landlady to employ a medical man, and he gave judgment for the plaintiffs, with costs.

VITAL STATISTICS.

THE VITAL STATISTICS OF ENGLAND, WALES, AND LONDON FOR 1909.

THE annual summary of marriages, births, and deaths in England and Wales and in London was issued on May 24th by the Registrar-General. The marriages in England and Wales during 1909 numbered 260,259, corresponding to a rate of 14·6 persons married per 1000 of the population at all ages. This rate was 0·3 per 1000 below the corresponding rate in 1908 and 1·1 below the average rate in the ten years 1899–1908. The births registered numbered 914,621, and were in the proportion of 25·6 per 1000 of the population at all ages. This rate was 0·9 per 1000 below the rate in 1908, and was lower than the rate in any other year on record, while compared with the average in the ten years 1899–1908 the birth-rate in 1909 showed a decrease of 2·2 per 1000. The deaths registered numbered 518,075, and were in the proportion of 14·5 per 1000 of the population. This rate was 0·2 per 1000 below the rate in 1908, and was lower than the rate in any other year on record. Compared with the average in the ten years 1899–1908 the death-rate showed a decrease of 1·6 per 1000. The diminution of infantile mortality more than counterbalanced an increase in mortality at the other extreme of life.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 9095 births and 4482 deaths were registered during the week ending May 14th. The annual rate of mortality in these towns, which had been 13·7, 13·1, and 13·1 per 1000 in the three preceding weeks, rose again to 13·8 in the week under notice, and was equal to the average annual death-rate in these towns during the first six weeks of the current quarter; in London the death-rate during the same period averaged 13·7 per 1000. The lowest recorded annual rates of mortality during the week in these 77 towns were 4·9 in King's Norton, 5·5 in Walthamstow, 6·2 in Devonport, and 6·5 in Handsworth (Staffs); the rates in the other towns ranged upwards, however, to 19·1 in West Bromwich, 19·7 in Manchester, 20·3 in Merthyr Tydfil, 20·4 in Burnley, and 21·5 in Huddersfield. In London the recorded death-rate in the week under notice was equal to 13·9 per 1000. The 4482 deaths registered in the 77 towns showed an increase of 224 on the low number returned in the previous week, and included 407 which were referred to the principal epidemic diseases, against 364 and 386 in the two preceding weeks; of these 407 deaths, 146 resulted from measles, 138 from whooping-cough, 49 from diarrhœa, 37 from diphtheria, 24 from scarlet fever, 12 from enteric fever, and 1 from small-pox. The mean annual rate of mortality in the 77 towns in the week under notice from these epidemic diseases was equal to 1·3 per 1000, against 1·2 and 1·1 in the two preceding weeks. No death from any of these diseases was registered last week in Rhondda, Derby, Southampton, Norwich, Wigan, or in nine other smaller towns; the annual rates therefrom ranged upwards, however, to 2·9 in Manchester, 3·9 in Burnley, and 5·9 in Bootle and in Merthyr Tydfil. The fatal cases of measles in the 77 towns, which had increased from 97 to 116 in the three preceding weeks, further rose to 146 in the week under notice; they caused annual death-rates equal to 2·0 in Stockport and in Dewsbury, 4·4 in Bootle, and 5·2 in Merthyr Tydfil. The deaths from whooping-cough, which had been 138 and 161 in the two preceding weeks, declined to 138 in the week under notice; the highest death-rates from this disease during the week were 1·2 in Plymouth, in King's Norton, and in Liverpool, 1·3 in Newport (Mon.), 1·5 in Manchester, and 2·4 in Burnley. The 49 deaths from diarrhœa also showed an increase upon recent weekly numbers. The 37 deaths attributed to diphtheria were 7 above the number in the previous week; they included 11 in London, 3 in Portsmouth, 3 in Leeds, and 2 in Stoke-on-Trent and in Liverpool. The fatal cases of scarlet fever, which had been 20 and 24 in the two preceding weeks, were again 24 in the week under notice, and

included 3 each in London, in Manchester, and in Liverpool, 2 in Birmingham, and 2 in Coventry. The 12 deaths referred to enteric fever included 3 in Manchester, 2 in London, and 2 in Portsmouth. The fatal case of small-pox belonged to South Shields. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily declined in the 30 preceding weeks from 2810 to 1506, further fell to 1476 during the week; 177 new cases of this disease were admitted to these hospitals during the week, against 192 and 197 in the two preceding weeks. Of the 1299 deaths registered in London during the week under notice 233 were referred to pneumonia and other diseases of the respiratory system, against 244 and 211 in the two preceding weeks; these 233 deaths were 19 below the corrected average number in the corresponding week of the five years 1905–09. The causes of 50, or 1·1 per cent., of the deaths registered in the 77 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death registered during the week were duly certified in London, Leeds, Bristol, West Ham, Bradford, Hull, and in 49 other smaller towns; the 50 uncertified causes of death in the 77 towns in the week under notice included 7 in Birmingham, 5 in Warrington, 4 in Manchester, 4 in Gateshead, and 3 in Stoke-on-Trent and in St. Helens.

In 77 of the largest English towns 6019 births and 4043 deaths were registered during the week ending May 21st. The annual rate of mortality in these towns, which had been equal to 13·1, 13·1, and 13·8 per 1000 in the three preceding weeks, declined to 12·4 in the week under notice. During the first seven weeks of the current quarter the annual death-rate in these towns averaged 13·7 per 1000, while in London during the same period the rate did not exceed 13·3 per 1000. The lowest recorded annual rates of mortality during last week in these 77 towns were 6·5 in Handsworth (Staffs), 6·7 in East Ham, 7·0 in Leyton, and 7·4 in Hornsey, the three latter being suburban metropolitan districts; the rates in the other large towns ranged upwards, however, to 19·0 in Newport (Mon.), 22·8 in Stockport, 23·1 in Tynemouth, and 27·5 in Merthyr Tydfil. In London the recorded death-rate last week did not exceed 11·4 per 1000. The 4043 deaths registered last week in the 77 towns showed a decrease of no less than 439 on the number returned in the previous week, and included 400 which were referred to the principal epidemic diseases, against 386 and 407 in the two preceding weeks; of these 400 deaths, 154 resulted from whooping-cough, 141 from measles, 37 from diphtheria, 32 from diarrhœa, 25 from scarlet fever, and 11 from enteric fever, but not one from small-pox. The mean annual rate of mortality in the 77 towns last week from these epidemic diseases was equal to 1·2 per 1000, against 1·2 and 1·3 in the two preceding weeks. No death from any of these epidemic diseases was registered last week in Plymouth, Birkenhead, Halifax, Swansea, Northampton, or in 10 other smaller towns; the annual death-rates therefrom ranged upwards, however, to 2·9 in Stockton-on-Tees, 3·0 in Manchester, 4·7 in Burton-on-Trent, and 7·2 in Merthyr Tydfil. The fatal cases of whooping-cough in the 77 towns, which had been 160 and 138 in the two preceding weeks, rose again to 154 last week; they caused annual rates equal to 1·8 in Manchester, 1·9 in Burton-on-Trent, and 2·0 in Newport (Mon.). The 141 deaths from measles were five below the number recorded in the previous week; the highest death-rates from this disease during the week were 1·9 in Stockton-on-Tees, 2·5 in Stockport, 2·8 in Burton-on-Trent, and 6·6 in Merthyr Tydfil. The 37 deaths referred to diphtheria were equal to the number returned in the previous week; they included 5 in Nottingham, 3 in Liverpool, and 2 both in Manchester and in Salford. The deaths attributed to diarrhœa, which had been 44 and 49 in the two preceding weeks, declined to 32 last week. The 25 fatal cases of scarlet fever showed but slight variation compared with recent weekly numbers, and included 8 deaths in London and its suburban districts. The 11 deaths referred to enteric fever included 2 in Manchester. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily declined in the 31 preceding weeks from 2810 to 1476, were again 1476 last week; 190 new cases of this disease were admitted to these hospitals during last week, against 179 and 177 in the two preceding weeks. Of the 1063 deaths registered in London during the week under notice 195 were referred to pneumonia and other diseases of the respiratory system, showing a substantial decline from the numbers returned in recent weeks; these 195 deaths were 34 below the corrected average number in the corresponding week of the five years 1905–09. The causes of 24, or 0·6 per cent., of the deaths registered in the 77 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death registered during the week were duly certified in London, Leeds, Sheffield, Bristol, West Ham, Newcastle-on-Tyne, and in 56 other smaller towns; the 24 uncertified causes of death in the 77 towns last week included 4 in Manchester and 3 both in Liverpool and in Preston.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 1047 births and 555 deaths were registered during the week ending May 14th. The annual rate of mortality in these towns, which had been equal to 17·4 and 15·6 per 1000 in the two preceding weeks, declined to 15·3 in the week under notice. During the first six weeks of the current quarter the death-rate in these towns averaged 16·9 per 1000, and exceeded by 3·1 the mean rate during the same period in the 77 largest English towns. The annual death-rates in the week in these eight Scotch towns ranged from 11·5 and 12·0 in Aberdeen and in Leith, to 21·3 in Greenock and 25·4 in Dundee. The 555 deaths from all causes in the eight towns during the week showed a decrease of 9 from the number in the previous week, and included 80 which were referred to the principal epidemic diseases, against 76 and 87 in the two preceding weeks. These 80 deaths were equal to an annual rate of 2·2 per 1000; the mean death-rate from the same diseases in the 77 English towns did not exceed 1·3 per 1000. These 80 deaths in the Scotch towns in the week under notice included 48 from measles, 15 from diarrhœa, 8 from whooping-cough, 4 from scarlet fever, 4 from diphtheria, and 1 from "fever," but not one from small-pox. The fatal cases of measles which had been 59, 44, and 52 in the three preceding weeks, declined in the week under notice to 48, and included 31 in Dundee, 9 in Glasgow, 4 in Greenock, and 3 in Edinburgh. The deaths from diarrhœa, which had been 16, 16, and 12 in the three preceding weeks, rose in the week under notice to 15; 7 were returned in Glasgow and 2 each in Edinburgh, in Dundee, and in Paisley. The fatal cases of whooping-cough, which had increased from 6 to 11 in the five preceding weeks, declined to 8 last week, of which 6 occurred in Glasgow and 2 in Dundee. Three of the 4 deaths from scarlet fever and 2 of the 4 fatal cases of diphtheria occurred in Glasgow. Only 1 death during the week was referred to "fever"; it was also recorded in Glasgow. The deaths in the eight towns referred to diseases of the respiratory system, which had been 93 and 77 in the two preceding weeks, rose in the week to 99, and were 7 above the number in the corresponding week of last year. The causes of 23, or 4·1 per cent., of the deaths in the eight towns in the week under notice were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death did not exceed 1·1 per cent.

In eight of the principal Scotch towns 872 births and 562 deaths were registered during the week ending May 21st. The annual rate of mortality in these towns, which had been equal to 15·6 and 15·3 per 1000 in the two preceding weeks, rose to 15·5 in the week under notice. During the first seven weeks of the current quarter the death-rate in these towns averaged 16·7 per 1000, and exceeded by 3·0 the mean rate during the same period in the 77 large English towns. The annual death-rates last week in these eight Scotch towns ranged from 11·2 and 12·6 in Aberdeen and in Leith, to 15·9 in Edinburgh and 20·8 in Dundee. The 562 deaths from all causes in the eight towns during last week showed an increase of 7 over the number in the previous week, and included 63 which were referred to the principal epidemic diseases, against 87 and 80 in the two preceding weeks. These 63 deaths were equal to an annual rate of 1·7 per 1000; the mean death-rate from the same diseases in the 77 English towns last week did not exceed 1·2 per 1000. These 63 deaths in the Scotch towns last week included 41 from

measles, 12 from diarrhœa, 7 from whooping-cough, 1 from scarlet fever, 1 from diphtheria, and 1 from "fever," but not one from small-pox. The fatal cases of measles in the eight towns, which had been 52 and 48 in the two preceding weeks, declined last week to 41, and included 23 in Dundee, 10 in Glasgow, 4 in Greenock, and 3 in Paisley. The 12 deaths attributed to diarrhœa showed a decline from the numbers in recent weeks; 6 were returned in Glasgow and 3 in Edinburgh. The single deaths from scarlet fever, from diphtheria, and from "fever" were recorded in Glasgow. The 7 deaths from whooping-cough showed a decline from the numbers in recent weeks, and included 5 deaths returned in Glasgow and 2 in Dundee. The deaths in the eight towns referred to diseases of the respiratory system, which had been 77 and 99 in the two preceding weeks, were 98 last week, and were 11 below the number in the corresponding week of last year. The causes of 18, or 3·2 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·6 per cent.

HEALTH OF IRISH TOWNS.

In Dublin 241 births and 170 deaths were registered during the week ending May 14th. The annual rate of mortality in this city, which had declined from 24·3 to 16·7 per 1000 during the three preceding weeks, rose again to 22·0 in the week under notice. During the first six weeks of the current quarter the annual death-rate in the city averaged 21·9 per 1000, whereas the mean rate in London during the same period did not exceed 13·7 per 1000. The 170 deaths in Dublin included 6 which were referred to the principal epidemic diseases, against 9, 7, and 3 in the three preceding weeks. The annual rate from these epidemic diseases did not exceed 0·8 per 1000; the rate from the same diseases in London in the week under notice was equal to 1·3. The 6 deaths from these epidemic diseases in Dublin in the week under notice included 3 from enteric fever, and 1 each from scarlet fever, whooping-cough, and diarrhœa. Of the 170 deaths from all causes 78, or nearly 46 per cent., were recorded in public institutions. The causes of 2, or 1·2 per cent., of the deaths were not certified. In Belfast 214 births and 170 deaths were registered during the week ending May 14th. The annual death-rate in this city, which had been equal to 23·1 and 22·3 in the two preceding weeks, rose to 22·7 per 1000 in the week under notice. Of the 170 deaths from all causes, 31 resulted from the principal epidemic diseases, equal to an annual rate of 4·1 per 1000, and included 23 from measles, 6 from whooping-cough, 1 from diphtheria, and 1 from enteric fever. The 170 deaths included 29 of infants under 1 year of age and 31 of persons aged upwards of 60 years, 4 deaths resulted from violence, and 41, or 24 per cent., of the deaths occurred in public institutions. The causes of 2, or 1·2 per cent., of the total deaths were uncertified.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 501 births and 431 deaths were registered during the week ending May 21st. The mean annual rate of mortality in these towns, which had been equal to 22·0, 20·1, and 21·3 per 1000 in the three preceding weeks, declined to 19·5 in the week under notice. During the first seven weeks of the current quarter the annual death-rate in these Irish towns averaged 21·7 per 1000, whereas the mean rate during the same period did not exceed 13·7 in the 77 large English towns and 16·7 in the eight principal Scotch towns. The annual death-rate during last week was equal to 15·9 in Dublin, 23·6 in Belfast, 22·6 in Cork, 15·6 in Londonderry, 10·9 in Limerick, and 17·5 in Waterford; the mean annual death-rate last week in the 16 smallest of these Irish town districts was equal to 23·8 per 1000. The 431 deaths from all causes in the 22 town districts last week showed a decline of 40 from the number recorded in the previous week, and included 59 which were referred to the principal epidemic diseases, against 43 and 41 in the two preceding weeks; these deaths were equal to an annual rate of 2·7 per 1000; in the 77 English towns the mean rate last week from the same diseases did not exceed 1·2 per 1000, while in the eight Scotch towns it was equal to 1·7. The 59 deaths from these diseases in the Irish towns last week included 45 from measles, 6 from whooping-cough, 4 from diarrhœa, 3 from scarlet fever, and 1 from enteric fever, but not one either from small-pox or diphtheria. The fatal cases of measles, which had been 20 and 24 in the two preceding weeks, further increased to 45 last week, of which no fewer than 44 occurred in Belfast. The 6 deaths from whooping-cough showed a decline from the numbers in recent weeks, and included 4 in Belfast. The 4 deaths from diarrhœa occurred in Dublin. The 3 deaths referred to scarlet fever included 1 each in Dublin, Cork, and Dundalk. The fatal case of enteric fever was recorded in Cork. The deaths in the 22 towns referred to pneumonia and other diseases of the respiratory system, which had been 93 and 120 in the two preceding weeks, declined to 84 last week. The causes of 12, or 2·8 per cent., of the deaths registered in the Irish towns last week were not certified; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·6 per cent., and in the eight principal Scotch towns it was equal to 3·2 per cent.

VITAL STATISTICS OF LONDON DURING APRIL, 1910.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 4·2 per 1000 of the population, estimated at 4,872,702 persons in the middle of the year. In the three preceding months the rates were 4·5, 4·6, and 4·1 per 1000 respectively. The lowest rates last month were recorded in the Cities of London and Westminster, and the Boroughs of Hampstead, Hackney, and Holborn; and the highest rates in St. Marylebone, St. Pancras, Finsbury, Deptford, Lewisham, and Woolwich. The prevalence of scarlet fever showed a slight increase over that recorded in the previous month; this disease was proportionally most prevalent last month in Chelsea, St. Pancras, Deptford, Greenwich, Lewisham, and Woolwich. The Metropolitan Asylums Hospitals contained 1489 scarlet fever patients at the end of last month, against 1962, 1740, and 2392 at the end of the three preceding months; the weekly admissions averaged 183, against 198, 204, and 180 in the three preceding months. Diphtheria was rather more prevalent in April than in March; among the several metropolitan boroughs this disease showed the greatest proportional prevalence in Stoke Newington, Finsbury, Bethnal Green, Stepney, Bermondsey, Lewisham, and Woolwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 883, 908, and 852 at the end of the three preceding months, had further declined to 794 at the end of last month; the weekly admissions averaged 75, against 96, 93, and 82 in the three preceding months. The prevalence of enteric fever showed a very marked decline from that recorded in the two preceding months; this disease was proportionally most prevalent in the City of Westminster, St. Marylebone, Finsbury, Bermondsey, Battersea, and Deptford. The Metropolitan Asylums Hospitals contained 66 enteric fever patients at the end of last month, against 62, 75, and 84 at the end of the three preceding months; the weekly admissions averaged 6, against 12 in each of the two preceding months. Erysipelas was proportionally most prevalent in St. Marylebone, Hackney, Finsbury, Shoreditch, Stepney, Southwark, Bermondsey, Deptford, and Greenwich. The 25 cases of puerperal fever included 3 in Stepney, and 2 each in Fulham, Islington, Hackney, Poplar, Southwark, and Woolwich. The 12 cases notified as cerebro-spinal meningitis included 2 in St. Pancras and 2 in Battersea.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in institutions having been distributed among the several boroughs in which the deceased persons had previously resided; the death-rates are further corrected for variations in the sex and age constitution of the population of the several boroughs. During the four weeks ending April 30th, the deaths of 4987 London residents were registered, equal to a corrected annual death-rate of 14·0 per 1000; in the three preceding months the rates were 14·8, 16·6, and 13·9 per 1000. The lowest death-rates last month were 9·7 in Hampstead, 10·3 in Woolwich, 10·4 in Stoke Newington and in Lewisham, 11·3 in Wandsworth, and 11·6 in Hackney; the highest

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING APRIL, 1910.

* Including membranous croup.

† The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

rates were 17·1 in Poplar, 17·5 in Southwark, 18·2 in Shoreditch, 19·6 in Holborn, 20·7 in Bermondsey, 21·0 in Finsbury, and 21·8 in the City of London. The 4987 deaths from all causes included 393 which were referred to the principal epidemic diseases; of these, 139 resulted from measles, 15 from scarlet fever, 24 from diphtheria, 164 from whooping-cough, 14 from enteric fever, and 37 from diarrhœa. No death from any of these epidemic diseases was recorded last month in Hampstead; among the other boroughs they caused the lowest death-rates in Kensington, Hammersmith, Chelsea, Stoke Newington, Bethnal Green, Wandsworth, and Woolwich; and the highest rates in St. Marylebone, St. Pancras, Finsbury, Shoreditch, Poplar, Southwark, Deptford, and Greenwich. The 139 deaths from measles were 107 fewer than the corrected average number in the corresponding period of the five preceding years; the greatest proportional mortality from this disease was recorded last month in Paddington, Fulham, Finsbury, Shoreditch, Southwark, Deptford, and Greenwich. The 15 fatal cases of scarlet fever showed a decline of 27 from the corrected average number; these 15 deaths included 3 in Southwark, and 2 each in St. Pancras and Lambeth. The 24 deaths from diphtheria were less than half the corrected average number in the corresponding period of the five preceding years; of these deaths 4 belonged to Islington, 3 to St. Pancras, 3 to Stepney, 3 to Poplar, 2 to Kensington, 2 to St. Marylebone, and 2 to Camberwell. The 164 fatal cases of whooping-cough were 20 fewer than the corrected average number; this disease was proportionally most fatal in St. Marylebone, St. Pancras, Islington, Finsbury, Shoreditch, Poplar, and Bermondsey. The 14 deaths referred to enteric fever were equal to the average number in the corresponding period of the five preceding years; these 14 deaths included 2 in Westminster, 2 in Islington, and 2 in Lambeth. The 37 fatal cases of diarrhœa were 14 below the corrected average number; the greatest proportional mortality from this disease was recorded in St. Pancras, Finsbury, Bermondsey, Camberwell, and Lewisham. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was 32·7 per cent. below the average.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned Staff-Surgeons have been advanced to the rank of Fleet-Surgeon in His Majesty's Fleet:—Thomas Tendron Jeans, John Hunter Pead, George Robert MacMahon, Robert Thomas Gilmour, Hilary Charles Arathoon, Thomas Williams Philip, Robert Spence Bernard, Lancelot Kilroy, James Mowat, Shirley Hall Birt, Montague Henry Knapp, Robert Dundonald Jameson, Hugh Somerville Burniston (dated May 16th, 1910).

Surgeons: W. H. King, F. C. Alton, H. E. R. Stephens, D. A. Mitchell, J. S. Ward, C. F. O. Sankey, D Horgan, R. N. W. W. Biddulph, E. McEwen, D. Loughlin, M. C. Mason, M. F. Caldwell, A. H. Joy, A. S. Paterson, and E L. Markham have been entered in the Royal Navy, with seniority of May 6th, and appointed to the *Victory*, additional, for a course of instruction at the Royal Naval Hospital, Haslar.

The following appointments are notified:—Fleet-Surgeons: E. J. Finch to the *Dominion*, temporarily, on recommissioning; J. K. Robinson to the *Cæsar*, on recommissioning; C. Bradley to the *Eagle*; and Hilary C. Arathoon to the *Hermione*, on recommissioning. Staff-Surgeons: Charles H. J. Robinson to the *Roxburgh*; Fairman R Mann to the *Blake*; James C. Bringan to Haslar Hospital; Paul H. M. Star to the *Gibraltar*, for voyage home; John Martin to the *Gibraltar* and to the *Fox*, on recommissioning; Oswald Rees to the *Gibraltar* for voyage home. Surgeons: John M. Gordon and Leonard Warren to the *Victory*, additional, for disposal; Alfred B. Cox, to the *Vivid*, for Royal Naval Barracks; Harold H. Babington, to the *Gibraltar*, and to the *Fox*, on recommissioning; George A. S. Hamilton, to the *Gibraltar*, for voyage home; Arthur R. Davidson, to the *Gibraltar*, and to the *Proserpine*, on recommissioning; James A. Thompson, to the *Pembroke*, additional, for disposal; George E. Hamilton, to Yarmouth Hospital; Charles J. Aveling, to the *Argonaut*, and for a division of special service vessels; Walter P. Yetts and James L. Barford to the *Pembroke*, additional, for disposal; T. E. Glunt, to the *Espiegle*; J. Hadwen, to the *Pembroke*, additional, for disposal; and W. E. Lloyd, to the *Dominion*, on recommissioning.

ARMY MEDICAL SERVICE.

Lieutenant-Colonel Menus W. O'Keeffe, from the Royal Army Medical Corps, to be Colonel, vice Colonel J. G. MacNeece, promoted (dated April 23rd, 1910.)

ROYAL ARMY MEDICAL CORPS.

The undermentioned Lieutenants are confirmed in that rank:—Theodore W. Stallybrass and Victor P. Hutchinson.

Colonel F. B. Maclean, Principal Medical Officer of the Seventh (Meerut) Division, has been granted five months' general leave. Brevet-Colonel R. H. Firth has been appointed Sanitary Officer on the Army Headquarters Staff, Simla, India, vice Lieutenant-Colonel A. R. Aldridge, tour expired. Lieutenant-Colonel D. Hennessy has arrived home from India on leave. Lieutenant-Colonel D. M. O'Callaghan has been appointed to the Charge of the Surgical Division of the Cambridge Hospital at Aldershot. Major E. B. Steel has been transferred from Jhansi to Neemuch. Major G. T. K. Maurice, from Muttra, has been posted for duty to the Southern Command. Major L. F. Smith, from Woolwich, has, on arrival in India, been appointed to the Station Hospital at Nowshera. Major G. B. Riddick, from Calcutta, has joined for duty at Maymyo, Burma. Major W. A. Ward has been transferred from the London District to the Southern Command and posted to Bulford Camp, Salisbury Plain. Major T. McDermott, on arrival from India, has been posted to the Eastern Command and appointed Specialist in Ophthalmology at Woolwich. Captain H. O. M. Beadnell has been granted six months' leave home from India. Captain R. R. Lewis, from Secunderabad, has been posted to Aldershot. Captain E. G. Ford has been transferred from Rawalpindi to Dehra Dun. Captain J. M. Cuthbert has arrived home on leave from the West Coast of Africa. Captain F. S. Walker, from Crownhill, has joined at Cahir for duty. Captain D. P. Johnstone, on return from a tour of service in Burma, has been posted to the Western Command. Captain K. A. C. Doig, from Bareilly, has been appointed to the Station Hospital at Shahjehanpur, United Provinces. Lieutenant A. D. Stirling has been transferred from Ashton to the Scottish Command and posted to Edinburgh for duty. Lieutenant A E. J. Frazer has arrived home from Egypt on leave. Lieutenant M. P. Leahy has been transferred from Poona to Kirkee. Lieutenant D. S. Buist, from Kingston-on-Thames, has been appointed for duty in the London District.

INDIAN MEDICAL SERVICE.

The King has approved of the following promotions among officers of the Indian Medical Service:—Majors to be Lieutenant-Colonels: Allan James Macnab, James Jackson, Henry Smith, Charles Neil Campbell Wimberley, Ernest Wickham Hore, Ashton Street, John Bland Jameson, William Dunbar Sutherland, Percy Carr-White, Edmund Hasell Wright, William Molesworth, Clarence Forbes Fearnside, Charles Arthur Johnson, and Gerard Godfray Giffard (dated March 31st, 1910). Lieutenant to be Captain: Norman Skinner Simpson (dated Sept. 1st, 1909).

The King has also approved of the retirement of the undermentioned officers: Lieutenant-Colonel Edulji Palanji Frenchman (dated April 1st, 1910); Lieutenant-Colonel Sarkies Carrapiet Sarkies (dated May 6th, 1910); Lieu-Colonel Winthropp Benjamin Browning, C.I E., Lieutenant-Colonel Dhanjibhai Barjorji Spencer (dated May 17th, 1910).

Lieutenant-Colonel A. C. Reeves has been reverted from civil to military employment. Lieutenant-Colonel J. M. Cadell, civil surgeon at Ghazipur, United Provinces, has been granted six months' leave. Lieutenant-Colonel H. Hendley, Bombay, has had his leave extended by two and a half months on medical certificate. Captain H. H. Thorburn has been granted leave for one year. Captain J. Connor, resident surgeon, Medical College Hospital, Calcutta, has been appointed to officiate as Civil Surgeon at Gaya, vice Lieutenant-Colonel Sunder. Captain H. M. Mackenzie, special health officer at Simla, has been appointed to officiate as Professor of Physiology at the Calcutta Medical College. The services of Captain

J. F. James have been placed temporarily at the disposal of the Government of Eastern Bengal and Assam. Captain R. A. Chambers has been appointed Officiating Superintendent of the Lahore District Jails, vice Captain N. H. Hume transferred. Captain D. H. F. Cowin has been posted as Officiating Civil Surgeon, Ferozopore, relieving Lieutenant-Colonel J. R. Adie, who has proceeded to Amritzar on deputation in connexion with the prevention of malarial fevers. Captain H. W. Pierpoint has been posted for duty to the Central Provinces under the Home Department. Captain W. T. Anderson has been granted two years' leave. Captain F. W. Cragg has arrived home on leave.

TERRITORIAL FORCE.

Infantry.

5th Battalion, The King's Own (Royal Lancaster Regiment): Arthur Henry Falkner (late Lieutenant, Royal Army Medical Corps (Territorial Force)) to be Lieutenant (dated March 24th, 1910). 4th Battalion, Alexandra, Princess of Wales's Own (Yorkshire Regiment): Surgeon-Lieutenant Clarence B. Whitehead to be Surgeon-Captain (dated Sept. 24th, 1909).

Royal Army Medical Corps.

1st Wessex Field Ambulance: Major Ransom Pickard to be Lieutenant-Colonel (dated March 29th, 1910).

For attachment to Units other than Medical Units.—Andrew George Tottenham Hanks to be Lieutenant (dated April 6th, 1910). Rupert Waterhouse, to be Lieutenant (dated April 15th, 1910).

DEATHS IN THE SERVICES.

Deputy Inspector-General Astley Cooper, R.N. (retired), at his residence, Chatsworth, Mannamead, Plymouth, on May 12th. The deceased officer entered the Royal Navy as a surgeon in 1857, became staff-surgeon in 1858, and was promoted fleet-surgeon in 1878. He was with the Royal Marine Brigade during the expedition of 1857–59, which included the blockade of the Canton river and the capture of the city, and was also in the expedition to the north of China in 1860. As principal medical officer he was at Shanghai during the repulse of the attacks on that city by the rebel army (China medal and clasp). He landed from the *Perseus* in 1869 and was at the capture of three walled villages near Swatow, China. During the Egyptian war of 1882 he was fleet-surgeon with Vice-Admiral Dowell on the *Minotaur* (Khedive's bronze star and the Egyptian medal). He retired from the service in 1889 with the rank of Deputy Inspector-General of Hospitals and Fleets.

Lieutenant-Colonel John Albert Anderson, A.M.S. (retired), on May 9th, at Paramé, France, aged 66 years. He joined the army as assistant surgeon in 1867; was promoted to surgeon in 1873; to surgeon-major in 1879, and to lieutenant-colonel in 1887, in which year he retired. He served in the Zulu campaign, 1879–80, and was present at the engagement at Ulundi (mentioned in despatches, medal with clasp).

THE LATE KING EDWARD VII. AND MIDDLESEX HOSPITAL.

At the Middlesex Hospital during the period intervening between the death and funeral of His late Majesty the flag flying half-mast high was lowered each night at sunset on the sound of "Retreat" by members of D Section, Medical Unit, University of London Officers' Training Corps, composed of students of the Middlesex Hospital Medical School. On the day of the funeral the section was paraded and attended a memorial service in the chapel attached to the hospital.

THE BRITISH RED CROSS SOCIETY.

On May 23rd a meeting of the committee of the City of London branch of the British Red Cross Society was held at the Mansion House under the Presidency of the Lady Mayoress. Various subcommittees were formed, and it was announced that the Prudential Assurance Company and Messrs. James Truscott and Son, Limited, would invite their employees to attend meetings convened for the purpose of securing their active interest in the movement.

The Duchess of Montrose presided at a meeting of the Stirlingshire Committee of the Scottish branch of the Red Cross Society held in the County Buildings, Stirling, on May 17th, when her Grace addressed those present on the objects of the society. Lieutenant-Colonel F. J. Greig, R.A.M.C. (retired), also addressed the meeting.

QUEEN ALEXANDRA'S IMPERIAL MILITARY NURSING SERVICE.

The War Office has issued the regulations for admission into the Queen Alexandra's Imperial Military Nursing Service. Candidates for the position of nurses must be between 25 and 35 years of age, single or widowed, and possess a certificate of not less than three years' training in medical and surgical nursing in a civil hospital having not less than 100 beds. They must be of British parentage or naturalised British subjects. The pay is as follows:—Staff-nurse, £40; Sister, £50; Matron, £75; Principal Matron, £175; and Matron-in-Chief, £305. All staff-nurses will be appointed provisionally for six months.

THE NAVAL AND INDIAN MEDICAL SERVICE DINNERS.

The annual dinners of these Services have been postponed this year in consequence of the lamented death of King Edward VII.

"Audi alteram partem."

A CASE OF BLACKWATER FEVER.

To the Editor of THE LANCET.

SIR,—Without attempting to discuss in detail the very important points raised by Major D. G. Marshall in his article on a case of blackwater fever in THE LANCET of May 14th, p. 1333, I should like to offer a few comments upon some of the special features of this case and to point what I consider the moral which should be drawn from it. The case quoted is unfortunately no isolated one, and it is because I believe that these attacks are in the main preventable that I venture to address you.

Let me recapitulate the main facts of the case. The patient in question goes out to West Africa in September, 1907. He takes quinine irregularly, and so at the end of six months has several slight attacks of malaria. He then takes quinine, five grains daily, and he has no more malaria. He returns to England in September, 1908, and in an evil moment gives up taking quinine at the very time when it was most urgent for him to take it—viz., when coming home during the treacherous British autumn. In Africa he was infected by the "malignant parasite" of malaria, the usual precursor of blackwater fever; this had been kept in check by quinine, but when he leaves off the quinine parasites again appear in his blood and he has a warning of malaria. Again he takes quinine for a month and then leaves it off again, and at the end of December he is exposed to the risks of winter in Edinburgh. On Jan. 6th he feels fever coming on, and is said to have taken "a large dose of sulphate of quinine," though how much he took or at what hour is not stated. That evening, however, he had two rigors and there was hæmoglobinuria. Apparently the urine never assumed the characteristic "porter" colour, and the yellow colouration of the skin which usually commences very soon after the onset of hæmoglobinuria does not seem to have been present until the fourth day, so that from several points of view the case was not quite an ordinary one. Some fever appears to have hung about the patient for some time until he took quinine again, when all fever left him.

Now what is the moral of this case? 1. That the only way to keep malaria in check by those who are liable to infection, or who show by the occurrence of attacks of malaria that they have been infected, is to take quinine. 2. That quinine must be taken regularly or it is useless, perhaps worse than useless, for it is the erratic taking of quinine which is most likely to produce unpleasant results. 3. That 5 grains of quinine a day is probably the best system, as any less regular system is not very likely to be rigidly carried out. 4. That the most important time to take quinine is on return to England, and for at least three months after, especially if the weather is cold, and for an even longer period if fever develops in England. 5. That whilst it probably is sound practice not to give quinine whilst the blackwater symptoms are present, yet quinine should be commenced in small gradually increasing daily doses immediately after. It may be added that it is the opinion of Professor Koch that if anyone will do this he will not suffer from blackwater fever or malaria again. 6. It

should therefore be clearly understood that in a person who has been infected by the malignant malarial parasite there is one, and only one, prophylactic, and that is quinine regularly and persistently taken. If only this were acted upon we should hear very little of blackwater fever.

As regards the question of return to the tropics after blackwater fever, this depends entirely upon the severity rather than the frequency of the attacks, and each case must be decided on its merits. It is certainly not the case that a man is immune after three attacks, and it is almost equally a mistake to say that "the chances of recovery from a second or third attack are ..... slight." I have had three attacks, and I know two medical men who have had a great many more.

I am, Sir, yours faithfully,

CHARLES F. HARFORD.

Livingstone College, Leyton, E., May 14th, 1910.

THE OPERATION FOR CLEFT PALATE.

To the Editor of THE LANCET.

SIR,—Several years have now elapsed since the introduction of what is known as the early operation for cleft palate, and it has been practised to such an extent that it has now become comparatively rare—amongst London patients at any rate—to find a child with this deformity at the age of a year or so who has not had an attempt, at any rate, made to remedy it. The success of such an operation can only be judged of after the lapse of a few years, and it would be interesting to learn how the ultimate results of this operation compare with those of the older methods and performed at a rather later period of the child's life.

I am led to make these remarks by having recently had under my care two children who had had the operation performed in their infancy; they came under my care for conditions quite unconnected with their deformity, one for empyema, the other for necrosis of the tibia. In both of them, to my mind, the result, as far as the palate was concerned, left much to be desired. It is true that in both of them the cleft had been closed over, but the palate that had been so fashioned was a most inefficient one, the soft palate was very short in an antero-posterior direction and terminated posteriorly in an almost straight transverse line, the movements of the soft palate were almost absent, and what little there was was irregular and one-sided, a result which, I think, must be in great measure due to the turning across of a flap, a proceeding which is almost necessary when operating on a wide cleft in an infant. As far as speech was concerned the result was very poor, and in one case, that of a child aged about 9 years, it was little, if anything, better than in a case where no operation had ever been performed. It may be, of course, that in these two cases the results had been exceptionally poor, but from the fact that the clefts in the palates were closed they were doubtless regarded as "cures" at the time of operation. These results compare very unfavourably with what can be obtained by median suture at a later period, and unless better results than those I have seen can be obtained I cannot help thinking it is a pity that so many of these cases should be operated on as infants and (in my opinion) spoiled for a more successful later operation. In cases where both the hard and soft palates are cleft I have always been an advocate for delaying the operation till the age of 18 months or 2 years, when it can be done by Fergusson's method, and this evidence of the results of the early operation has strengthened my conviction that the older plan is to the best interests of the patient's future. It would be interesting to know the experience of others in this matter.

I am, Sir, yours faithfully,

Queen Anne-street, W., May 21st, 1910. THOS. H. KELLOCK.

THE EXPIRATORY NATURE OF STRIDOR IN BRONCHIAL ASTHMA.

To the Editor of THE LANCET.

SIR,—In Dr. Brian Melland's extremely illuminating article on Bronchial Asthma and its Treatment by means of Hypodermic Injections of Adrenalin the writer expresses inability to account for the expiratory nature of the stridor in this affection. In lecturing upon laryngeal as distinguished from other forms of stridor, it has been my custom in describing the inspiratory rhythm of the noise in laryngeal obstruction to compare it with the bronchial stridor which is characteristically expiratory. I have ventured to offer the following explanation—namely, that during inspiration expansion of the chest walls is accompanied by a dilatation (more or less marked according to the nature of the tissue) of all the hollow structures in the cavity, including the bronchial tubes, so far as the rigidity of their structures will permit; in expiration, on the other hand, the contraction of the chest causes a simultaneous compression of the contained organs. Thus during the latter phase the bronchial tubes, already narrowed, become still more narrow than before, and in the former one the asthmatic contraction is to a slight extent neutralised by the expiratory dilatation. If this does not express the whole of the truth I am quite convinced that it expresses some of it, and I think it will help to fill up the lacuna in Dr. Brian Melland's description.

I am, Sir, yours faithfully,

London, W., May 23rd, 1910. DUNDAS GRANT.

ASSOCIATION OF MEDICAL DIPLOMATES OF SCOTLAND.

To the Editor of THE LANCET.

SIR,—May I call the attention of Licentiates of the Royal Colleges of Physicians and of Surgeons of Edinburgh to the fact that they have been excluded from the addresses of sympathy recently sent by the Councils and Fellows of those corporations to His Majesty the King and to the Queen-Mother. With the wording of those addresses all must agree: with simple eloquence they express sympathy, allegiance, loyalty, and congratulations. But why at this supreme moment of sorrow are the Licentiates, who compose the bulk of the Colleges, denied the opportunity of sharing in a graceful tribute to their beloved Sovereign and his Queen-Mother? Could any more striking example of the absolute indifference of council-governed colleges towards their Licentiates and Members be imagined than this?

As President of the Association of Medical Diplomates of Scotland I beg to say that if a sufficient number of Scotch Licentiates and Members will send me their authorisation I will see that an address worthy of the Licentiates and Members of our ancient Colleges is prepared and forwarded to the proper quarter. All that will be required is to send me a post-card stating that the Licentiate writing wishes to add his or her name to the address of sympathy to be sent to the King and the Queen-Mother, and to add name and qualifications.—I am, Sir, yours faithfully,

D. WALSH, M.D. Edin.

48, Welbeck-street, London, W., May 24th, 1910.

THE LATE DR. E. CRESSWELL BABER.

To the Editor of THE LANCET.

SIR,—I should like, in addition to your obituary notice of Dr. Baber, to say a word or two of appreciation of his many good qualities and of his many kindnesses to myself.

I first met him when I became desirous of joining the Royal Ear Hospital staff in 1895, and when, in 1897, I became his house surgeon at that institution I commenced a pleasant association with him that only death has cut short. Dr. Baber had, among his many good qualities, that of attracting those in intimate association with him by his never-failing courtesy and kindly nature. He was, perhaps, rather a shy man, but once one got beneath his (apparent more than real) reserve one could not but appreciate his great kindness of heart and ever-readiness to help another. Of his capabilities as an organiser and his skill as an otologist and laryngologist I need not speak, the success of the Otological Congress in 1899 and his work in hospital and private practice were sufficient evidences. What I wish especially to emphasise is his personal charm, and I shall always cherish his memory as one of those who make life easier to those around them.

I am, Sir, yours faithfully,

MACLEOD YEARSLEY, F.R.C.S. Eng.,

May 21st, 1910. Senior Surgeon to the Royal Ear Hospital.

THE MIDWIVES BILL AND POOR-LAW RELIEF.

To the Editor of THE LANCET.

SIR,—Dr. Major Greenwood's letter of May 7th on the Midwives Bill and Poor-law Relief in my mind opens the ground for another big discussion. In a few years' time will medicine as a profession be worth following? I am in practice in a working-class town, and what with midwives and district nurses midwifery is nothing to what it was, and as time goes on I am very much afraid that in a town like this we shall only be called in to emergency cases, and may or may not get our fees; at present for emergency work it is generally the latter.

There is another very serious question, too: our medical officer of health was appointed as a whole-time official, to do the medical officer of health's work, inspection of school children, and look after the isolation hospital, and was not to practise. Now what do we find? We find that the inspection of the school children has gone a step further, and that the children are being treated by the medical officer of health at his office for ringworm, otorrhœa, diseases and troubles of the eyes, and other minor ailments that one finds with the school children, and the parents of the majority of the cases treated are quite in a position to pay the fees asked in a locality such as this. We then go on a step further and find that the patients in isolation hospital are being afforded minor operations that they can and would willingly undergo at home, and so the poor general practitioner is once more suffering and placed at a disadvantage. It seems very forcible to me that these latest moves, supposed to be in the interests of the children, are tending only more and more to pauperise the working classes. I have used the word pauperise because there is no other word that fits the case so well. And the medical man is asked to pay income-tax, rates and taxes, &c., to help to take his own living away from him. I enclose my card, but for obvious reasons desire my name and address to be withheld.—I am, Sir, yours faithfully.

ONE WHO BELIEVES IN PARENTAL RESPONSIBILITY.

May 17th, 1910.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bonn:* Professor Verworn of Göttingen has been offered the Chair of Physiology vacated by the death of Professor E. Pflueger.—*Cincinnati (Miami Medical College):* Dr. Henry Martin Fischer has been appointed Professor of Physiology.—*Halle:* Dr. Karl Grouven of Bonn has been appointed Extraordinary Professor of Dermatology; Dr. Hermann Hildebrandt, *privat-docent* of Pharmacology, has been granted the title of Professor.—*Heidelberg:* Dr. Th. Lebar, Professor of Ophthalmology, who has now completed his seventieth year, is about to retire; Dr. K. Laubenheimer, formerly of Giessen, has been recognised as *privat-docent* of Hygiene, having followed his chief, Professor H. Kossel.—*Kahrkoff:* Dr. J. M. Penski, Extraordinary Professor of Surgery, has been promoted to be an Ordinary Professor.—*Limoges:* Dr. Donnei has been appointed Professor of Clinical Surgery and Dr. Vouzelle Professor of Clinical Midwifery.—*Modena:* Dr. Giuseppe Ovio has been appointed Extraordinary Professor of Ophthalmology and Dr. C. Ferrai Extraordinary Professor of Forensic Medicine.—*Moscow:* Dr. A. A. Maklakoff, *privat-docent*, has been appointed Professor of Ophthalmology.—*Parma:* Dr. Giusto Coronedi of Sassari has been appointed Professor of Materia Medica and Experimental Pharmacology.—*Philadelphia (Jefferson Medical College):* Dr. Francis T. Stewart has been appointed to the Chair of Surgery in succession to Dr. W. Joseph Hearn, resigned.—*Rio de Janeiro:* Dr. Francisco Simoes Corrêa has been appointed Extraordinary Professor of Children's Diseases in succession to the late Dr. Candido Barata Ribeiro.—*St. Petersburg (Military Medical Academy):* Dr. A. L. Poliênoff has been recognised as *privat-docent* of Surgery.—*Tomsk:* Dr. A. Lindström, Extraordinary Professor of Dermatology, has been promoted to the Ordinary Professorship.—*Vienna:* Dr. Wilhelm Wiechowski, of the German University of Prague, has been appointed Extraordinary Professor of Pharmacology. Dr. Alfred Tröhlich has been recognised as *privat-docent* of Pharmacology.

HEALTH PROBLEMS IN THE POTTERIES AND THE FEDERATION OF THE SIX TOWNS.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

Stoke-on-Trent, May 2nd, 1910.

AFTER many years' discussion the "Six Towns," once known as the "Five Towns," have united. Burslem, Fenton, Hanley, Longton, Stoke, and Tunstall have amalgamated under the name of Stoke-on-Trent into one borough. Hanley, with its population of close upon 70,000, was the most important town of the six, though Stoke was the chief railway centre and had the most ancient ecclesiastic history, for no less than 28 parishes have been carved out of its territory. But it was at Burslem that Josiah Wedgwood regenerated the potter's art, and, as a matter of fact, each of the six centres has its particular claims to be considered as the most important constituent of the group. Such records have led on several occasions to a keen display of parochial patriotism, stimulated by the fact that in any scheme of fusion there would be but one mayor where there had been six mayors, while all the principal municipal dignitaries would be proportionally decreased in number. The one borough that replaces the six towns came into existence on March 31st, and already it is settled that there shall be but one town clerk instead of six town clerks. This will be an economy in the long run, but will probably cost more at first for the usual reasons which prevail in these situations—viz., the dispossessed town clerks will receive pensions and the new town clerk with the increased responsibilities of the single post will have a commensurate salary. The question of the medical officers of health will probably be settled in the same fate, though this has not yet been decided. The six medical officers of health receive salaries that vary from £100 to £200 a year and are also in private practice, the appointments being part-time ones. It is now proposed to have but one medical officer of health for the united six towns, who will be a whole-time official, and who, it is suggested, will be paid £800 a year.

A Question of Headquarters.

Before deciding all the details of unification the new borough council had to fix its own headquarters. So great was the fear of appearing to show any preference for any one of the six towns that the first meeting was held at the largest hotel in the six, viz., the Stafford Hotel. Then the council decided that it would meet in the six town halls each in turn without preference or favour. After this experience it might be able to decide which of all these buildings was the most suitable. Apparently, however, everybody knows already which is the most suitable, for not only is the town hall at Hanley the largest, but the old Hanley town council, anticipating that the federation of the six towns would take place sooner or later, actually built a council chamber large enough to hold the new council whenever it came into existence. On the other hand, both Stoke and Burslem, being dissatisfied with their town halls and apparently not believing that the federation would be brought about for many years to come, have just begun building new town halls. Now these buildings will not be wanted as town halls, though they can be used for meetings, concerts, balls, and various shows or entertainments. Will the new borough council, which consists of 104 members and therefore requires ample space, select one of the new town halls now in course of construction, will it go to Hanley where a large enough council chamber already exists, or will it build yet another town-hall especially for itself? Whatever may be the ultimate solution of this problem it is essential that the council should not only have a convenient meeting place but that the offices for all the services should be close at hand, if possible under the same roof. Further, the offices need to be not only large enough for the increased staff now needed but for additions which will surely be brought into existence by forthcoming social legislation. We used to have school boards on one side and municipal bodies on the other. Now the two governing bodies are merged into one, and the space occupied by the centralised administration needs to be very large. Obviously there will be a great alteration effected sooner or later in our Poor-law administration, but even if the boards of guardians share the

fate of the school boards the work will have to be done somewhere, and if more is done—which would be the justification for the change—more aggregate space would be required. Even without any such vast change the existing services are likely to increase. Thus if private slaughter-houses are suppressed and there are established public abattoirs on modern lines, the offices under the Markets Committee will have to be larger than those needed at present. The offices of the medical officers of health also may need considerable enlargement if, as has been proposed, all services bearing upon health, not only the medical inspection of school children but also the poor relief to the sick, are united under one head. Any of these changes may occur at Stoke-on-Trent, while if the new council purchases the tramways and the water-supply totally new offices will be required. It is doubtful if any of the existing town halls will be big enough for the new borough if many of the expected developments occur. Towns of 30,000 to 70,000 inhabitants are not to be compared to this new borough, which has a population of a quarter of a million. It would be folly to begin with unsuitable premises; inconveniences due to unforeseen developments accumulate only too soon in the course of time. Thus it seems to me that the new council should start in life with plenty of elbow room and ample provision for the likely increase in the number of services it will have to take in hand.

Problems Facing the Council.

There are some very complex problems facing the new borough which have their origin in the fact that the six towns should have amalgamated many years ago, or should at least have instituted joint boards, as was actually done to some extent in the provision of an isolation fever hospital. There is the Hanley, Stoke, Fenton, and Longton Joint Hospital Board, in which case four out of the six towns are united in respect to hospital accommodation for the isolation of infectious diseases. But they did not all join together at once. They came in according to the order indicated by the title of the board. Now what will be done? Will this board be dissolved and a municipal committee substituted? Will the patients from Burslem and Tunstall be taken to the hospital of the four other towns? This, however, is a minor question when compared with that of the drainage system. For this purpose a joint board should have been formed years ago, for it is absolute folly that towns touching one another should each have a separate drainage system. If many years ago the six towns were really separated by wide spaces and open fields, they are now in such close touch that the inhabitants themselves have forgotten the boundary lines. From Tunstall at the extreme north to Longton at the extreme south there is a distance of about six miles, and east and west for distances varying from a quarter of a mile to two and even three miles there are houses, works, and potteries closely built or touching one another, and constituting one great mass of dwellings and workshops that must be considered and governed as one great town. Yet and often in direct contradiction to what the conformation of the land indicates should be done, there are at present six totally different schemes of drainage with separate sewage disposal works. Unfortunately, some of these latter have only recently been installed and have not yet been paid for. Will the whole of the new borough have to be taxed to pay for liabilities incurred by only one out of the six towns now federated? This would be particularly hard if the works should prove of no use to the general scheme of drainage to be introduced for the whole of the newly constituted borough. As it is the fall is from Hanley to Stoke. The Hanley sewage disposal works had to be built at a somewhat higher level than the frontier line between Hanley and Stoke. If the sewers were continued from Hanley into Stoke there would have been no difficulty, but at the time when this must have suggested itself to engineers the two towns would not work together. So the Hanley sewage stops at the Stoke frontier, and four Shone ejectors have to be employed to raise up the lower portion of Hanley sewage to the level of the Hanley sewage disposal works. Obviously such complications would not have arisen had there been a joint drainage scheme, and now that all the towns are federated such a joint scheme should be introduced. The same arguments apply to many other questions, such as the water-supply, the tramway service, the public abattoir question, and other matters that intimately concern the health and the comfort of the population.

The look-out is very interesting and in many directions very promising. When legislative sanction is needed for some great reform, such as the compulsory closing of private slaughter-houses, it will be much more easy for the borough of Stoke-on-Trent with its quarter of a million inhabitants to meet the expense of promoting a Bill in Parliament than it would have been for any one of the six towns to make such an attempt. Such considerations engender the hope that an era of great reforms is dawning on the Staffordshire Potteries.

In discussing these matters with the sanitary authorities and local medical practitioners it became obvious that by federation the six towns would more easily realise those reforms that are urgently needed. The Potteries do not enjoy a good reputation in regard to public health. So much is this the case that on several occasions the Local Government Board has had to hold official inquiries. Undoubtedly one of the first requirements is cheap water, and it will be much easier for a big borough to obtain this necessity than for a number of small local authorities. The water is needed to flush the sewers, but, above all, to flush the domestic drains.

Infantile Mortality.

There has been very high infantile mortality in the Potteries, and this has led to the denunciation of specific evils. For instance, much was said concerning the prevalence of lead poisoning. That this used to be a cause of miscarriages is certain, for these accidents ceased on the women leaving the works where lead glaze is made for the pottery. But this does not occur now, in any case not to the same extent. Nor can the excessive deaths of the infants be attributed solely to the fact that their mothers go to work. At all events, at Longton it has been established that only 25 per cent. of the mothers of certain defunct infants went to work. The chief cause seems to be insanitary surroundings, coupled with the ignorance of the parents, who do not know how to feed their infants or how to bring them up in a cleanly manner. There is the excessive prevalence of summer infantile diarrhœa, but mothers are as ignorant, dirty, or careless in winter as in summer. If, therefore, the results are worse in summer, this is the consequence of insanitary conditions, and first among these is the cesspool system. Given proper drainage the mother's ignorance would not produce such disastrous effects.

Fortunately, and most wisely, the authorities have attempted to deal with both evils. The towns have appointed lady sanitary inspectors whose special mission it is to call on young mothers and endeavour to teach them how to nurse their infants. This fact alone goes a long way towards explaining the gratifying reduction of infantile mortality during recent times, though of course there are many other reasons and notably the partial improvement of the drainage. As the new borough has only just come into existence, it possesses no record of its own. To take up the statistics of each of the six towns separately would be a very lengthy process; but the conditions of the towns do not greatly vary, therefore two or three examples will suffice to illustrate the main matters at issue. Thus at Longton there is a population of 38,287, which is equal to an average of 5·14 inhabitants per house. The birth-rate in 1909 was 33·4 per 1000, and therefore considerably above the birth-rate of both the large and small towns of England and Wales. Yet it is a decreasing birth-rate. The death-rate was 17·0 per 1000, and therefore also higher than the average of the towns, which was 14·7 in the 76 largest towns. Now the infantile death-rate was 156 per 1000 births at Longton, 118 in the 76 largest towns, and 111 in the 143 smaller towns. If figures have any significance, these statistics undoubtedly testify to a very serious situation, though when compared to the record of previous years they undoubtedly indicate that a great improvement has been effected. Thus, ten years ago, in 1900, the infant mortality at Longton was equal, per 1000 births, to 255·7. In 1902 it had fallen to 195·7, but rose the following year to 215·1. Then it was just a little below 200 till 1906, when it rose again to 234·5. In 1907 it was only 170; in 1908 it was 183. These figures engender the hope that a permanent and substantial reduction has been effected.

The education in the care of children afforded by lady sanitary inspectors who call on young mothers has had

good effect. The same may be said concerning the obligations on employers to apply methods of ventilation and facilities for washing and other measures to reduce the risk of lead poisoning among the workers. It would be well if in this respect the workers could be induced to make better and more constant use of the means given them to cope against the danger of absorbing the lead dust. Whatever there may be to say concerning the education of the workers in the Potteries or of the young mothers in their homes, these important problems are not directly affected by the federation of the six towns. But if coercion of any sort is necessary, and especially if new by-laws are required, then the federation of the six towns will prove a decided advantage. A rule is now needed, for instance, to abolish all privy cesspools. But it would be absurd to compel effective drainage of one side of a street because the street was in one town and to leave another side of the same thoroughfare alone because it is in another town. These towns touch each other and often are only separated by the partition walls of the houses. The problem of infantile mortality has already been bravely attacked in the six towns, but reformers will find their work simplified by federation.

Cesspools and Public Health.

The study of the records published by the medical officers of health clearly shows that to wait till the households voluntarily introduce proper domestic drainage is to unnecessarily sacrifice many human lives. It is true that the figures given indicate that there was a marked improvement at Longton last year, but nevertheless we find that out of the 15 cases of enteric fever notified 14 lived in houses where there was no water-closet, and in none of these houses were the drains ventilated. Of the 21 deaths from July to October among infants due to diarrhœa one lived in a house where there was a water-closet, six lived in houses with privy cesspools, and 14 in houses where the closets have no water but must be flushed, when they are flushed, by hand. If we take the closet accommodation for the whole town it will be found that there are 1809 houses with privy cesspools, 927 with slop-water closets, 350 with fresh-water automatic closets, 3088 with hand-flushed pans, and only 2021 houses with proper cistern-flushed water-closets. The statistics of previous years show how enteric fever and diarrhœa find the greater part of their victims where the system of drainage is most faulty. Thus in 1907, when the infantile mortality was comparatively low—namely, 170 per 1000—there were 23 deaths of infants during the summer from diarrhœa, and again only one of these children lived in a house with a proper water-closet. Twelve of the houses had hand-flushed pans, and three of these were noted as being especially dirty, six houses had cesspools, and four the system by which the dirty slop water flushes the pan. There were 27 cases of enteric fever notified that year, and not one of them occurred in a house with a water-closet, but six took place where there were cesspools, and all the other houses had inferior systems of drainage.

The year 1906 was a very bad year. The general death-rate was 22·9, and the infantile mortality reached the alarming figure of 234·5 per 1000 infants. This was due in great measure to diarrhœa, which was responsible from August to October for the death of 102 infants and 18 children under five years of age. Now no less than 51 of these victims lived in houses where there were cesspools, and only seven in houses with water-closets. There were 44 houses with hand-flushed pans, 24 of them being in a filthy condition, and there were 10 with closets that depend on dirty slop-water for such cleansing as they may get. In the same year 32 cases of typhoid fever took place in 30 houses; of these, five houses had water-closets but one of them was not ventilated. The previous year, 1905, there were 26 cases of enteric fever in 20 houses, and not one of these dwellings had a water-closet, but no less than 13 had privies. There were 41 deaths from summer diarrhœa—35 infants and six children. Among the dwellings where these deaths occurred, only two houses had water-closets, but 21 had cesspools. It would be difficult to find more emphatic figures. In 1904 there were 2867 privy cesspools and only 1369 water-closets. The latter we have seen increased to 2021 in 1909 and the privies decreased to 1809. Thus, during the greater part of the period mentioned above the decreasing number of cesspools and increasing number of water-closets have a tendency to equilibrate; and were both systems equally good there should be no marked difference in the number of deaths occurring in houses with water-closets and houses with cesspools. Yet for the four years for which I was able to obtain the figures—1909, 1907, 1906, and 1905—there were 99 deaths from enteric fever, of which only seven occurred in houses with water-closets and 92 in houses that had some inferior system of drainage, including 33 cesspools. In the same period there were 205 deaths from infantile epidemic summer diarrhœa, including in that figure a few children under 5 years old. Of these, only 11 occurred in houses with water-closets, whilst out of the remaining 194 deaths no less than 84 took place where the old cesspool system is still preserved.

Undoubtedly the cesspools are not alone to blame. The houses with water-closets are inhabited by the more fortunate and well-to-do sections of the community. But even making every allowance for these social and economic differences, the cesspool system stands condemned, and this new evidence only confirms what sanitary reformers have energetically urged for now more than half a century. But to abolish the cesspools and to compel all householders to connect with the sewers that fortunately exist throughout the district the local authorities must have increased powers. Then water-closets are not practical unless there is sufficient and cheap water. For this also the larger the authority, the more wholesale the transaction, the cheaper will be the results. It is in such matters that the Potteries will benefit from the federation of the six towns.

(To be continued.)

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

University of Bristol and a Proposed Settlement.

Professor Lloyd Morgan presided over a large and enthusiastic meeting held recently in the large hall of the University, which was addressed by Dr. John Kelman of Edinburgh on the subject of university settlements. Among the many admirable points upon which he laid stress was the fact that a settlement provided means for the study of "clinical" economics, without which no university could pretend to teach the subject of economics satisfactorily; by such means it was to be hoped that the time would come when public administrators would be trained for their work as thoroughly as those who enter other professions. He congratulated the University of Bristol on the inclusion of a settlement as an integral part of itself while it was still in its infancy. A resolution welcoming the formation of a settlement was passed with acclamation; and Professor G. H. Leonard, who spoke in support of the resolution, said that it was proposed to make special facilities for the training of persons for Local Government Board posts and other administrative appointments.

An Officers' Training Corps.

The Officers' Training Corps is an organisation for the training of officers in two divisions. The junior division consists of the cadet corps of the public schools, reorganised and coördinated, and the senior division has been in the same way built up from the Universities' Volunteer Corps, together with the Inns of Court and Artists Rifles. Men pass from the junior to the senior division, and from the latter into the Territorial Force or into the Special Reserve. The University of Bristol, which was without a Volunteer organisation at the time when the Officers' Training Corps was formed, has now done its share by the creation of an infantry contingent, which, though small at present, is certain to grow, and may, it is hoped, become the nucleus of a department of military education in Bristol. The contingent will go to camp at the end of July with similar contingents from several other Universities, including Birmingham, whose adjutant, Major Loring, of the Royal Warwick Regiment, acts in a similar capacity for the Bristol contingent.

Agricultural Research.

The famous Bath and West of England Agricultural Society has made arrangements with the University of Bristol for the investigation of insects and other pests on

behalf of farmers without charge, and for experimental research and systematic instruction relative to the manufacture of cider.

May 24th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool Medical Institution and King George V.

AT a special meeting of the Liverpool Medical Institution held on May 19th, Dr. T. R. Bradshaw, the President, being in the chair, an address to His Majesty King George V. was adopted. The adoption of the address was moved by Dr. A. T. H. Waters, the senior past-president of the society, seconded by Mr. Chauncy Puzey, past-president, and supported by Mr. Edgar A. Browne, also a past-president. The text of the address is as follows:—

To the King's Most Excellent Majesty,—

The Members and Associates of the Liverpool Medical Institution desire to record their deep sorrow at the death of their beloved Sovereign, King Edward VII. They desire to express their appreciation of the sympathy which, throughout his memorable career, he manifested with every movement for the social and physical advancement of his subjects, and more especially with the work of the medical profession, which he showed in a signal manner by graciously consenting to be enrolled among the Fellows of the Royal College of Physicians and of the Royal College of Surgeons. They respectfully offer to your Majesty, and your Majesty's Royal Consort, to her Majesty the Queen-Mother, and to the other members of your Royal house, their profound sympathy in the loss which you and they, together with the whole British Empire, have sustained, and they beg to assure you of their loyalty and attachment to your Majesty's Throne and person.

West Derby Guardians and Medical Appointments.

At a recent meeting of the West Derby guardians the clerk reported the receipt of the following communication from the secretary of the Local Government Board:—

I am directed by the Local Government Board to acknowledge the receipt of your letter of the 20th ult., and to express their satisfaction on learning that the guardians of the West Derby Union have passed a resolution that in future no applicant for an appointment under the board of guardians who is a member of the board, or who has been a member of the board within a period of six months prior to the date of such appointment, shall be eligible. In the circumstances the Board will not offer objection to the appointment of Mr. H. M. Mitchell as district medical officer. They accordingly approve of the payment to him of the salary of £150 per annum for his services, and now direct that the said salary shall be paid to him by the guardians in accordance with the terms of the orders in force on that behalf. The Board request to be informed as soon as Mr. Mitchell has removed into his district.

Hospital Saturday in Liverpool.

In connexion with the Liverpool Hospital Saturday Fund, the various firms and their employees who contribute week by week to this excellent institution on Saturday last made up their accounts with the object of forwarding their annual remittances to the honorary secretaries of the fund. Since the establishment of the fund as much as £179,360 4*s.* 5*d.* have been collected and distributed in conjunction with the Hospital Sunday Fund to the various medical charities. An urgent appeal was now made, and as an incentive to a more generous support of the fund the guarantors have notified that they will be prepared to double any increase of contributions over the total received during the year 1906. A special supplementary collection was made on Saturday amongst the workpeople towards the fund.

The Birkenhead Guardians and the Need for Isolating Small-pox Patients.

At a meeting of the Birkenhead guardians held on May 3rd attention was again called to the absence of an isolation block for small-pox patients, and it was decided to send copies of the correspondence between the board of guardians and the corporation of Birkenhead to the Local Government Board.

Small-pox Outbreak in New Ferry, near Birkenhead.

A serious outbreak of small-pox, directly traceable to the escape of a patient from the Liverpool Port Sanitary Hospital, which is located at New Ferry, on the Birkenhead side of the Mersey, has occurred there, no fewer than 14 patients being in the hospital. The incident which is regarded as the inception of the outbreak occurred a short time ago. A Spaniard had been taken to the hospital suffering from small-pox, and, in a state of delirium, rose suddenly from the bed, and overpowering the night nurse jumped through a window. Escaping practically unhurt he roamed about the district for some time before being captured, coming into contact with several residents in the meantime. The first case of the disease was reported on May 15th, when a man living in Prospect-place, a poor neighbourhood, was found to be suffering from a mild form of small-pox. His little son, however, was suffering from a very serious attack, and was promptly removed to hospital. Since then 14 cases, all in the same street, have been notified, and all of these have been taken to hospital—7 to the port sanitary hospital and 7 to the small-pox hospital at Greasby. The most rigorous preventive measures have been adopted by the acting medical officer of the district under the instructions of the health committee of the Lower Bebington district council. The inhabitants of all the houses in which cases have occurred have been sent to Pensby, where they are accommodated under canvas. Prospect-place has been barricaded off in order that people may not traverse it until the fear of infection is no longer existent. The strictest surveillance is being exercised to prevent the disease becoming epidemic. All the schools were temporarily closed. The first patient found suffering from small-pox stated that he had been in contact with the Spaniard on the night of his extraordinary escapade. Experience of former epidemics proved that the "conscientious objector" to vaccination realises that discretion is the better part of valour, and in such an experience throws his objections to the winds and requisitions the services of the public vaccinator.

WALES.

(FROM OUR OWN CORRESPONDENT.)

Tuberculosis Dispensary for Cardiff.

THE medical officer of health of Cardiff, Dr. E. Walford, has laid before the health committee of the corporation as a preliminary communication that section of his annual report for 1909 which has reference to the prevention of tuberculosis. Among the preventive measures which have already been adopted by the corporation are the voluntary notification of cases of phthisis, the provision of facilities for the gratuitous bacteriological examination of suspected sputum, the distribution to the poor of spit-bottles free of charge, and such educational measures as are included in the distribution of literature and in the instruction given by health visitors and sanitary inspectors. There is, however, no special dispensary for cases of phthisis, such cases being treated at the out-patient department of the Cardiff Infirmary, at the Provident Dispensary, by the Poor-law medical officers, and by private practitioners. Dr. Walford considers that a central and special tuberculosis dispensary under municipal control would very much facilitate the organisation of a proper system of home visitation by the health visitors employed by the corporation, and would be the means of securing the early diagnosis of patients suspected to be suffering from the disease. He points out that the health committee already possesses suitable accommodation which could be set apart for the purpose of a dispensary, and suggests that an additional health visitor should be appointed and the services of a medical officer retained at an honorarium of £50 per annum. The cost of drugs and instruments he estimates at £25 per annum. The institution would thus be carried on at an annual charge of less than £200 yearly. The health committee has accepted the principle of the proposals, so it may be assumed that there will be no great difficulty in giving effect to them.

Pontypridd Cottage Hospital.

In spite of the great liability of the workmen to accidents there is a noticeable absence in some of the colliery districts of South Wales of hospital accommodation. Merthyr Tydvil possesses a well-equipped hospital with about 50 beds; at Aberdare and at Mountain Ash there are small cottage hospitals with 10 or 12 beds; and at Porth, in the Rhondda Valley, there is a cottage hospital with accommodation for 20 patients. The town of Pontypridd, which has a population of over 40,000 persons, is at present unprovided with any such institution, although successful efforts are being made to provide one. On the hillside overlooking the town and near to the celebrated rocking stone a site has been given, and

nearly £4000 have been subscribed towards the cost of erecting a small hospital. The foundation stone of the building was laid on May 5th by Lord Tredegar. The central portion of the hospital will be of two storeys, and on either side will be one-storey wings. The accommodation provided will be for 14 patients.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Medical Attendance in the Highlands.

THE annual report of the medical officer of health of Inverness-shire reveals a somewhat startling state of affairs apparently existing in the Highlands. From his report it would appear that 259 deaths in the county—i.e., over 27 per cent.—have not been certified by a medical practitioner. This, unfortunately, appears to be due not so much to an absence of official formalities as to a lack of medical attendance in the Highlands, and particularly in the Islands. This obviously represents much suffering, loss of life, and misery which might be obviated if medical attendance were available. The great difficulty, no doubt, is not only the difficulty of communication but the sparseness of population in the Highlands. A special grant by the Treasury in aid of medical attendance would certainly help matters.

Infantile Mortality in Dundee: Interesting Information.

In his annual report Dr. C. Templeman, medical officer of health of Dundee, remarks that the sanitary state of the city may be considered satisfactory. The deaths numbered 18·15 per 1000 and the births 27·29 per 1000. Deaths from consumption numbered 288. Dr. Templeman gives a history of the negotiations for the transference of Sidlaw Sanatorium to the corporation, and he points out that since the system of voluntary notification came into force in May, 1907, only 526 cases have been notified, and as showing the inadequacy of the system he remarks that the number of deaths last year exceeded the notifications by 122, and that no fewer than 189 of the deaths were first intimated to the department by the registrars. The death-rate of infants under one year was equivalent to 21·7 per cent. of the total mortality of the city and 144 per 1000 births. With regard to the scheme inaugurated in 1907 by the Home Office to inquire into the effect of the employment of married women on infant mortality, the coöperation of the medical officers of health in large industrial centres had been asked, and in Dundee the conclusions come to, after careful statistics had been compiled, were: (1) that the employment of mothers is an important factor in the high infantile death-rate; and (2) that the deaths of infants seem to recur in the same families. Dr. Templeman remarks on the growth of the unvaccinated population in the city.

Preliminary Examinations at the Scottish Universities.

The preliminary examination statistics for the four Scottish Universities have now been published. For the preliminary examination in medicine 10 entered at St. Andrews, 122 entered at Glasgow, 45 entered at Aberdeen, and 126 at Edinburgh. The percentage of candidates entered for the four requisite subjects and who passed in all these subjects in the four Universities taken together was 29·11. In Glasgow the percentage was 25·80, in Aberdeen it was 34·78, in Edinburgh 30·55, and in St. Andrews 20. It must be noted, of course, that this takes no account of students who commence their medical studies without entering the preliminary examination on account of their holding the necessary leaving certificates.

May 23rd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Annual Elections at the Royal College of Surgeons.

THE election of President, Vice-President, Council, and secretary of the Royal College of Surgeons in Ireland is to take place on Monday, June 6th. Mr. R. H. Woods, the distinguished laryngologist, who is Vice-President at present, will not be opposed in his candidature for Presidency. Of late years it has been taken as fixed that the Vice-President should succeed to the higher office without opposition. For the vice-presidency there are at least two candidates in the field—Dr. R. D. Purefoy and Mr. J. B. Story. Dr. Purefoy is, of course, one of the leading obstetricians in Dublin, and ex-Master of the Rotunda Hospital, whilst Mr. Story is an ophthalmologist and surgeon to the Royal Victoria Eye and Ear Hospital. In addition, Mr. J. S. McArdle some time ago announced his intention of presenting himself this year as a candidate for the vice-presidency. Considerable interest is likely to be taken in the election of the Council on the present occasion, as it is expected that the newly-formed Association of Fellows will make itself felt. It is stated that the association contains already more than a hundred members, and it is obvious that if any large proportion of them vote in a body they will exercise a very distinct influence. Many of them, too, are resident in England or at a distance from the College, and are likely to be willing to be guided by the general policy of the association as decided by its executive committee. It is not yet clear what that general policy is to be, but it is thought that the association is not quite sympathetic with the more progressive party in the Council.

Post-Graduate Courses at the Royal College of Surgeons.

Two post-graduate courses are announced to take place under the auspices of the College. The first course will cover the period from June 6th to 28th, 1910, and the second course from Sept. 26th to Oct. 18th, 1910. The fee for each course is 5 guineas. The object is to render available the whole of the clinical material in Dublin for the post-graduate student, so that he may see as much as possible during the time at his disposal. The course will be continued in a circuit at the ten chief hospitals, besides various hospitals devoted to special subjects, according to a syllabus and daily time-table, of which a printed copy can be obtained on application to the secretary of the Post-Graduate Course, Royal College of Surgeons, Stephen's Green, Dublin. A list of apartments and certain hotels at modified rates may also be obtained.

Poor-law Reform in Ireland.

The forthcoming session of the Irish Medical Association, to be held in Dublin on June 7th, is likely to be important, since at it will be discussed the policy of the profession in Ireland as regards Poor-law reform. As stated some weeks ago,[1] the council of the Irish Medical Association is taking a plebiscite of the members of the Association concerning a report issued by its special committee on Poor-law reform and adopted by the council. The main point at issue is between schemes for a National Medical Service and for county services. There is little doubt that the majority of the profession in Ireland is in favour of a National Service, but, nevertheless, there will be a respectable body of opposite opinion. It is to be doubted whether, even with the results of the plebiscite before it, the Association will in one afternoon session be able to come to a decision, since, of course, there are domestic and various other matters also for discussion. It is felt to be important, however, that the views of the profession in Ireland should soon be definitely formulated, more particularly as the British Medical Association is preparing schemes for England and Ireland, and there may be danger that the problems of the two countries should be confused. Everyone in Ireland, lay or medical, is convinced that the Irish problem should be treated by itself.

The Medical Profession in Ireland and the Death of King Edward.

Addresses of condolence with Her Majesty the Queen-Mother and with His Majesty King George have been adopted by the Royal Colleges of Physicians and Surgeons. In addition, both Colleges, together with the Universities and other learned bodies, were represented officially at the memorial service held in St. Patrick's Cathedral on May 20th, as well as at the votive mass at the Pro-Cathedral on the same day. The Lord Mayor being at Windsor, Alderman Dr. J. C. McWalter, who acts as his locum-tenent, attended with the members of the corporation in state at the Pro-Cathedral.

The Death of Lady Thompson.

General sympathy is felt with Sir William J. Thompson,

[1] THE LANCET, April 23rd, 1910, p. 1169.

Registrar-General, in the sudden death last week of his wife by a tramway accident. In reaching for the bell-strap she fell off the platform of the car, fracturing her skull.

The County Antrim Infirmary.

At a meeting of the committee of management of this institution on May 18th, Mr. G. L. St. George, surgeon to the hospital, complained of statements made at a recent meeting of the committee of the county council to the effect that patients from the northern end of the county were refused admission, and that the place was run by a few ladies. Mr. St. George emphatically denied these statements. A gentleman, a member of the infirmary board of management, who had been on a deputation to the county council, stated that there was a great deal of misapprehension in the minds of the county councillors which should be dispelled. They seemed not to be aware that the infirmary was really a county institution. It was also stated that 14 members of the county council were entitled to attend the meetings of the infirmary board of management, and yet none had inquired as to the statements made, and while they were all provided with books of admission lines they had not issued any. It was finally decided to put the whole matter in the hands of a committee, which is to deal with the county council. It appears that the county council contributes £600 per annum, a sum which would only keep the infirmary going for six months in the year.

The Children Act Committee.

Councillor A. Trimble, M.D., has been elected chairman of the new committee appointed by the Belfast city council to deal with the Children Act.

Medical Appointment.

The post of medical examiner of naval recruits and local agent for the Belfast district, which is in the gift of the Crown, is now vacant. There are a great many applicants.

May 24th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

King Edward VII. and the Berlin Medical Profession.

THE unexpected death of King Edward VII. created a general feeling of sorrow and sympathy in this country and was especially regretted by the medical profession of Berlin. It may be remembered that during his recent visit to this city the King, notwithstanding the shortness of his stay and its well-filled programme, had, nevertheless, found time to meet some members of the medical profession and to visit a medical institution. As already mentioned in THE LANCET, he was shown over the Empress Frederick House, an institution for post-graduate study, originally under the patronage of the late Empress Frederick. King Edward spent some time in seeing over the establishment, and even attended a short lecture delivered by Professor Kutner, the director. All the medical men who had the honour of being introduced to his Majesty and of conversing with him were full of admiration for his unostentatious manner, his good humour, and unfailing courtesy.

Serum Treatment of Scarlet Fever.

At a recent meeting of the Berlin Medical Society Dr. Jochmann, physician to the Virchow Hospital, read a paper on Modern Methods of Treatment of Scarlet Fever. He said that streptococci were present in the organs of the great majority of scarlet fever patients, especially in those who had died from complications. Although it was uncertain whether streptococci were the exciting cause of the disease, Dr. Jochmann had obtained good results by the administration of antistreptococcic serum, especially of that which was prepared at the Höchst factory, according to the method of Dr. Meyer and Dr. Ruppel. The serum was tried exclusively in serious cases, for instance, in those in which the pyrexia persisted even after the exanthem had begun to fade, partial necrosis of the palate and swelling of the cervical glands being also present, sometimes with cyanosis, cardiac failure, and troubles of the sensorium. It was also tried in cases which were likely to prove fatal, cases in which on the first and second day the patients showed toxic symptoms, cyanosis, high fever, coldness of the extremities, unconsciousness, and thready pulse. Of 400 patients in the Virchow Hospital, 62 belonged to the grave and probably fatal category. As a rule, 50 cubic centimetres of the serum were administered by subcutaneous injection, and the dose was if necessary repeated after two days or oftener when no effect was visible. In very grave cases with imminent prospect of death an intravenous injection was given. In most cases the antistreptococcic serum was combined with Sir Almroth Wright's vaccine—a method which gave better results than serum alone. 28 cases, with 9 deaths, were treated by serum alone; 44, with 15 deaths, were treated by a combination of serum and vaccine. Among the 24 fatal cases 10 from the first gave no hope of success, either because the organisms which were present were not streptococci but staphylococci, or because there was concurrent diphtheria, or because the patients had arrived in the hospital in a moribund state. The remaining 14 patients suffered from an extremely severe form of scarlet fever with deep necrosis of the palate, suppuration of the cervical glands, cardiac failure, and delirium, while cultures yielded an enormous growth of streptococci. With regard to the patients who recovered, Dr. Jochmann said that the good effect became visible as a rule in from 24 to 36 hours, but sometimes, however, only after the second or third injection. Complications developed in only seven of the cases treated by serum, and Bright's disease did not ensue even once, although hæmorrhagic nephritis was a special feature of this year's epidemic. Undesirable symptoms due to the serum treatment itself included an exanthem resembling urticaria, which developed in eight cases; pains in the joints also occurred, and in one instance a pre-existing insufficiency of the mitral valve became worse after an intravenous injection. Dr. Jochmann said that the Höchst serum was, of course, not an ideal remedy against scarlet fever; in septic cases, where the blood was overcharged with streptococci, the patients could not be saved by the serum; cases with incipient necrosis of the tonsils and incipient toxæmia were suitable for this form of treatment.

Death of Professor Lenhartz.

Professor Hermann Lenhartz, chief physician to the Eppendorf Hospital in Hamburg, died in that city on April 20th, at the early age of 55 years, from pernicious anæmia. He had been an assistant to the late Professor Wagner of Leipsic, the well-known pathologist, and at first devoted himself almost exclusively to pathological anatomy. Subsequently he became extraordinary professor of clinical medicine and chief of the Leipsic University Polyclinic. In 1895 he went to Hamburg to become a chief physician to the hospitals, first to the St. George's Hospital and afterwards to the Eppendorf Hospital, and the organisation of the great Hamburg hospitals was for the greater part his work. He devised and described many valuable therapeutic methods. His published memoirs on lumbar puncture, on the operative treatment of gangrene of the lungs, on the dietetic treatment of gastric ulcer, on the puncture of typhlitic suppuration, and on the Karell treatment of heart disease and obesity were of a specially original character. He also wrote several valuable treatises on clinical microscopy, chemistry, diseases of the respiratory organs, erysipelas, and various septic diseases. When the death of Professor Lenhartz became known to the Medical Congress at Wiesbaden the President, in his eulogy on the deceased, rightly characterised him as one of the greatest physicians of Germany.

May 23rd.

CANADA.

(FROM OUR OWN CORRESPONDENTS.)

Medical Registration in the Dominion of Canada.

REGISTRATION for the whole Dominion has been again shelved. Manitoba, Saskatchewan, Alberta, and British Columbia have agreed upon a basis of interprovincial reciprocity, and the plan is likely to be put into effect in the near future.

Alexandria Hospital for Infectious Diseases in Montreal.

The annual meeting of the governors of the Alexandria Hospital of Montreal was held recently under the presidency of Dr. Roddick. The chairman, in his speech, referred to the lack of accommodation for mixed infectious cases in the

hospital and also for erysipelas patients. The greatest drawback, however, he said, was the inadequate accommodation for nurses. In fact, the building of a nurses' home seemed to him imperative. With these three wants supplied—namely, a pavilion for mixed infectious cases, an erysipelas pavilion, and a nurses' home—Dr. Roddick doubted if a more thoroughly equipped institution for the treatment of contagious diseases could be found in the world.

Opening of the New Buildings of the Medical Faculty of McGill University.

It is hoped that the new buildings of the Medical Faculty of McGill University, erected to replace those destroyed by fire some three years ago, will be ready for occupation in the early part of the summer. The opening of the buildings on June 6th and 7th is to be attended with striking ceremonies. The Medical Faculty has decided to hold the next annual Convocation for the conferring of the degrees in medicine in the new building at the same time. It is expected that more than 500 former medical graduates of McGill will take part in a reunion, which will last several days. The Governor-General will take an active part in the ceremonies, and an elaborate programme of entertainments has been prepared.

A New Home for the Toronto Academy of Medicine.

Owing to the fact that the University of Toronto is unable to give permission to the trustees of the Academy of Medicine to erect buildings on the present site the trustees have been compelled to seek the necessary ground elsewhere. It is understood that they have been offered an excellent site in Queen's Park and that building operations will be commenced shortly. The Massey estate has promised to contribute several thousand dollars to a building fund, and between £7000 and £8000 will be expended in providing a suitable building.

Resignation of Dr. Charles Sheard, Medical Officer of Health of Toronto.

Dr. Charles Sheard, who has been medical officer of health of Toronto during the past 18 years, has resigned the position.

A Bill for the Sterilisation of Criminals, Idiots, and Imbeciles.

Dr. Forbes Godfrey, a member of the Ontario Legislature, introduced a Bill during the present session for the sterilisation of criminals, idiots, and imbeciles, somewhat similar to the well-known Indiana edict. The Premier, Sir James Whitney, spoke very strongly against the Bill, which was withdrawn.

Amendments in the Regulations of the Ontario Medical Council.

An amendment of much importance has been made recently in the regulations of the Ontario Medical Council. As soon as any registered practitioner is convicted in any court of Ontario of a criminal offence his name is now automatically removed from the Register. Another amendment is to the effect that the executive committee of the Council may now institute inquiry into alleged cases of infamous conduct upon its own initiative and report to the Council. This avoids the delay which occurred formerly, as when the Council ordered an investigation nothing could be done for a year.

Farm Inspection of Milk Supplied to Montreal.

Dr. McCarrey, the chief food inspector of Montreal, has made a report to the Montreal Board of Control which he thinks will result, if carried out, in a far more pure milk-supply for the city than at present exists. He has suggested in the report that farms outside Montreal which supply milk shall be subject to inspection. The report shows that within a radius of 100 miles of Montreal there are no less than 800 farms which send milk to the city and which are not inspected. It is therefore requested that the controller appoint ten new milk inspectors, six of whom are to be employed solely for visiting farms, seeing that these are kept in a cleanly condition, that no cows are milked which are suffering from tuberculosis and that cattle-sheds are properly ventilated. In addition to inspecting farms and milk, it will be the duty of the inspectors to give farmers practical lessons as to how milk should be handled in order to prevent it from becoming contaminated. Dr. Lachapelle, who is at the head of the Montreal Board of Control, is said to be strongly in favour of a system of farm inspection of milk, cows and premises.

Children Poisoned by Pills in Canada.

A somewhat large number of deaths has been reported from all parts of Canada as the result of small children obtaining and eating pills and capsules. Parents are careless and leave pills and capsules in places from which children can easily obtain them. Medicines in these forms are, for the most part, coated with sugar, chocolate, or other sweet-tasting substance, and the child eats sufficient either to kill it or seriously to injure its health. Of course, such accidents cannot be prevented by legislation, for they are dependent wholly on the carelessness of parents.

May 17th.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENT.)

Another Martyr to Science.

IN my letter published in your issue of April 23rd I mentioned the appointment of Dr. Howard T. Ricketts, associate professor of pathology at the University of Chicago, to the newly reconstituted professorship of pathology at the University of Pennsylvania. It is now my melancholy duty to record his death under circumstances that mark him as one of the martyrs to science before either he could benefit from the high honour and substantial emoluments so recently conferred on him, or the University could profit from his teaching and research work. Dr. Ricketts, who was yet a young man, having been born in 1871, graduated so recently as 1897, and spent the intervening years to date in teaching and scientific research. His work on blastomycosis and on spotted (or Rocky Mountain) fever is widely known and had already earned for him a foremost place among medical research students in this country. It seems that when agreeing last year to accept the professorship of pathology tendered to him by the University of Pennsylvania, he stipulated that it should not interfere with his freedom to pursue his studies of typhus fever in Mexico until the end of the present summer. He had already achieved results in this direction worthy of his reputation, when he was himself stricken with the disease, just as he was on the point of completing his studies. Following on the typhus fever he had spinal meningitis, and died in the American Hospital at the City of Mexico on May 3rd.

Death of Dr. H. L. Burrell.

I have also to report the death of Dr. Herbert Leslie Burrell, of Boston, which occurred on April 27th at the age of 54, from cardiac and renal disease. Dr. Burrell was professor of clinical surgery at Harvard University, and was president of the American Medical Association in 1908–09.

May 14th.

Obituary.

GEORGE WILLIAM CHASTER, M.R.C.S. ENG., L.R.C.P. LOND.

Mr. G. W. Chaster, who died on May 5th, was son of the late Mr. G. W. Chaster of Wigan. He had a brilliant academical career at University College, Liverpool, became Jones scholar in 1882, was Torr gold medalist in 1883, and in 1885 was appointed assistant demonstrator in physiology at the University. In 1889 he won the Holt Tutorial Scholarship, and became assistant demonstrator in anatomy and clinical assistant at the Liverpool Royal Infirmary. In 1889 he took the diplomas of M.R.C.S. Eng. and L.R.C.P. Lond. He was in active practice in Southport until a recent period. In 1896 he was appointed honorary assistant on the medical staff of the Southport Infirmary, and in 1903 was appointed one of the honorary medical staff, which office he filled until 1907, when ill-health compelled him to retire as consulting medical officer, a position which he retained to the time of his death. In all his work in connexion with the Southport Infirmary the self-sacrificing nature of his character came into full play, and that institution certainly had no more faithful

and devoted member on its medical staff. His activities were not confined to his profession. He ever associated himself zealously with the popularisation of natural science. He was one of the founders of the Southport Society of Natural Science, and at one time its president, and contributed from time to time some valuable original papers to its Transactions, particularly on the subjects of the local mollusca and foraminifera, on which he was an admitted authority. He acquired a most valuable collection, now bequeathed to the Southport Science and Art Schools. He did much original work in the identification of the foraminifera of the dredged material from the late *Challenger* and *Porcupine* expeditions. One year he held the important office of president of the Conchological Society of Great Britain and Ireland. He was a man of exceptionally keen powers of observation and laborious patience; thoroughness and single earnestness were characteristic of a life in great part devoted to scientific research. He will be sadly missed from the ranks of the profession and in connexion with many philanthropic agencies.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Heinrich Curschmann, professor of medicine and director of the Medical Clinic in the University of Leipsic, has died suddenly from cardiac disease, at the age of 63 years. He was born in Giessen and studied medicine in the University there, afterwards going to the Rochus Hospital, in Mayence. In 1871 he migrated to Berlin, where he had the advantage of working under Professor Traube. He was appointed to the Moabit Hospital as one of the physicians, and in 1888 succeeded Professor E. L. Wagner as professor of medicine and director of the Medical Clinic in the University of Leipsic. Since then a number of his pupils have shown by their distinguished careers what an excellent teacher they had had. His own works included "The Relation of the Labyrinth of the Ear to the Body Weight," many papers on Psychic Hæmianopia, Bronchial Asthma, Infectious Diseases, Hospital Construction, and Kidney and Intestinal Diseases. He wrote several of the articles in Ziemssen's and Nothnagel's Cyclopædias. His "Clinical Portraits with Descriptive Text," which is a very well-known work, was published in 1894.—Dr. Gustav Edlefsen of Hamburg, who was formerly extraordinary professor of medicine in the University of Kiel and director of the Medical Polyclinic there. He published a large text-book on the Diagnosis of Medical Diseases in 1899.—Dr. Ditlevsen, formerly *privat-docent* of histology in the University of Copenhagen.—Dr. Cordier, formerly surgeon to the Lyons hospitals.—Dr. Trolard, professor of anatomy in the Algiers Medical School and corresponding member of the Paris Academy of Medicine.—Dr. Oskar Riegner, for many years senior surgeon to the Breslau Hospital, aged 66 years.—The two senior members of the profession in Germany have just passed away within a few days of one another—viz., Surgeon-General Paschen of Ludwigslust, aged 95 years, and Dr. Stolpe of Potsdam, aged 94 years.—Dr. John Landström, lecturer on surgery in the Stockholm Medical School.—Dr. J. Afanassieff, professor of therapeutics in the Clinical Institute of the Grand Duchess Helen Paulovna, St. Petersburg.—Dr. Vittorio Mibelli, professor of dermatology in the Parma Medical School.

UNITED SERVICES MEDICAL SOCIETY.—A clinical meeting of this society was held at the Royal Army Medical College on May 11th, Lieutenant-Colonel R. H. S. Sawyer, R.A.M.C., being in the chair. Major W. S. Harrison, R.A.M.C., showed two cases of disseminated sclerosis and read notes on one of primary spastic paraplegia. He remarked that the cases were interesting from two points of view: first, that two of the patients dated their illness from an attack of enteric fever; and, secondly, as showing how very varied the symptoms of disseminated sclerosis might be. Notes on a case of dysentery with gumma of the liver were read and pathological specimens of the liver and large intestine were exhibited. Lieutenant G. H. Dive, R.A.M.C., exhibited a case of congenital acholuric icterus. The chief points to which attention was directed were jaundice, variability in the depth of the jaundice, splenomegaly, oligocythæmia, anisocytosis, diminished mean diameter of the red cells, absence of bile in the urine, and presence of bile in the fæces.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

TUESDAY, MAY 24TH.

THE General Council of Medical Education and Registration commenced its summer session at its offices, 299, Oxford-street, W., to-day. Sir DONALD MACALISTER, the President, occupied the chair.

New Members.

Three new members took their seats at the Council.

Mr. ARTHUR TREHERN NORTON, C.B., F.R.C.S., was introduced by Sir HENRY MORRIS as representative for one year of the Apothecaries' Society of London.

Sir WILLIAM WHITLA, M.A., M.D., LL.D., took his seat as representative for a term of three years of the Queen's University of Belfast. He was introduced by Sir JOHN MOORE.

Mr. ARTHUR NEWSHOLME, M.D., M.R.C.S., who is a Crown nominee for England for a term of five years, was introduced by Dr. NORMAN MOORE.

The President's Address.

The PRESIDENT then delivered his presidential address. The members of the Council rose whilst the President made reference to the death of King Edward. The President said:—

We meet on the day associated for generations with the illustrious name of Queen Victoria, amid the tokens of a nation's mourning for the passing of her illustrious son and successor on the Throne. In the sudden grief which has stricken the Royal House and all the subjects of the Crown the members of our profession have shared to the full. They can appreciate, better perhaps than others, the kingly courage of our late beloved Sovereign, who under the approaches of his malady refused to yield to any but the last inexorable summons, and while conscious life remained strove resolutely to fulfil the duties of his exalted station. Nine years ago the Council at his accession hailed His Majesty as one who had ever evinced a wise and effectual interest in all that concerned his people's health. His reign, short as it was, abundantly justified the acclamations with which it began. It will ever be memorable on account of the beneficent undertakings for the well-being of his subjects which King Edward initiated or fostered, no less than for its great achievements in the cause of peace and concord among the nations. Happily for us, His Majesty King George has already shown that His Royal father's interests and sympathies are also his own, and that we may confidently reckon on his enlightened solicitude for every national institution whose purpose is to further the moral and physical amelioration of the peoples committed to his care. It will, doubtless, be your desire that I should presently, as our first business, propose from the chair that the Council tender to His Gracious Majesty a humble and loyal address expressive of our sympathy with the personal sorrow of the Royal Family and of our devotion to His Majesty's Throne and person. Its terms may well echo those of the address which His late Majesty was pleased to accept in 1901, for our feelings and our hopes concerning King George are in perfect consonance with those we sought to express in approaching King Edward.

After ten years of valued service Sir Hugh Beevor and Sir William Henry Power have retired from the Council. The one in relation to the work of the Executive and of the Students' Registration Committee, and the other in relation to that of the Public Health Committee, have long enjoyed the Council's confidence and repeatedly earned its gratitude. We part from each with a sense of personal loss, for each made himself a friend as well as a colleague; and we trust that each will carry with him a cordial remembrance of the Council and its activities. Mr. Arthur Trehern Norton, C.B., will in future represent the Apothecaries' Society of London, and Dr. Arthur Newsholme, who worthily occupies Sir William Henry Power's position at the Local Government Board, now succeeds him here by the appointment of His Majesty in Council. To them, and to Sir William Whitla, the representative of the new Queen's University of Belfast, whose

eminence is recognised wherever scientific therapeutics are studied, we offer the right hand of fellowship. We are sure that they will find in the Council fresh opportunities of applying their talents and their experience for the benefit of the public. Before long we may expect the further addition of three new members to our number, by appointment of the Universities of Wales and of Bristol, and by direct election of a fourth representative of the registered practitioners of England and Wales. The problem of accommodating the Council thus enlarged may offer some difficulty; but meanwhile the Registrar has, by some readjustment of seats, made provision that will meet the immediate need. We are still faced by the problem of finance. By such husbanding of our resources as is practicable we have reduced the deficit of £656, reported last year, to a deficit of only £146 in the financial year now closed. But with the prospect of a costly election in the near future, and the greater expense of a larger membership, it is scarcely possible to expect that income and expenditure will so nearly balance during the succeeding years. The cost of our judicial proceedings is hardly within our control; and though we have sought a way of lessening it through some process of delegation, the acumen of our advisers has not yet succeeded in discovering a method that is free from legal or practical objections. The task of exhaustively revising the Medical Register, begun by the Registrar and his staff in 1908, has now been completed, with the result that the volume is probably more accurate than it has ever been before. The work has involved an enormous amount of correspondence with practitioners all over the world, and much research in books of reference, University and College Lists, and Colonial Registers. In one year over 14,000 alterations or additions had to be made in the Register, many perhaps trivial in character, but all necessary for correctness. Taking account of the fees paid for the entry of additional qualifications and the like, the cost of the whole revision is less than £165, and in view of the fact that during the process communication has been established, directly or indirectly, between the office and every person whose name is on the Register, it will be agreed that though the labour involved has been heavy the charge on the Council's funds has been justifiable and moderate. Special thanks are due to the Registrar for directing the operations, and to Mr. King, Mr. Cockington, and Mr. Storr for carrying them out with efficiency.

Turning to external matters, I have to report that the Legislature of Prince Edward Island has passed an Act enforcing a five years' course of study at an approved University or school of medicine on candidates for the qualifying examinations conducted by its Medical Council. The Executive Committee has accordingly agreed to recognise the provincial diploma or licence in medicine, surgery, and midwifery as a qualification registrable in the Colonial List, in pursuance of His late Majesty's Order in Council of Jan. 10th, 1910. Information has reached me that a conference is about to meet in Canada, at which representatives of the medical authorities of the several provinces will discuss the possibility of federal action in regard to medical registration within the Dominion. Should the conference lead to the ultimate establishment of a Canadian Medical Register in place of or in addition to the numerous provincial registers now in use, the question of reciprocity as between this country and the Dominion would be greatly simplified. I cannot help expressing the hope that this result may be speedily attained. It would certainly strengthen the bonds that unite us to our professional brethren beyond the seas were British medical qualifications, whether registered in the Home or the Colonial List, to become valid throughout the Empire.

Our legal adviser's attention was called to a private Bill which was introduced in the House of Commons early in the year at the instance of the Apothecaries' Society of London. The Bill proposed to authorise the Society to confer diplomas in dental surgery and in various special branches of medicine. It also proposed that the Medical Council should be required to accept certain of these diplomas for registration under suitable conditions, though similar diplomas conferred by other licensing bodies are not at present registrable under any conditions. The Executive Committee was advised that the proposals referring to the Medical Council involved an amendment of the Medical Acts, which, if made at all, should be made by means of a public Act, and should be rendered applicable to other licensing bodies. A representation to this effect was accordingly transmitted to the Government. On the matter coming before the House of Commons in March the Speaker ruled that the proposals in question were not of such a nature as should be dealt with by a private Bill, and the measure was thereupon withdrawn from the consideration of the House. The Executive Committee has also been informed that the Privy Council received a petition from the Apothecaries' Hall of Ireland, praying that the Medical Council might be directed to recognise the Preliminary Examination in general education held by the Apothecaries' Hall as sufficient for the registration of medical students. The Lords of the Council decided that the subject-matter of the petition did not fall within their purview, and informed the governing body that they were unable to comply with the prayer of the petition.

The Departmental Committee on Coroners, which was instructed by the Secretary of State for the Home Department to report also on the subject of anæsthetics, has issued its conclusions. These are in general accordance with the resolutions adopted by the Council at its last session. The resolutions have also (except as to one point of detail) been endorsed by the Council of the Royal College of Surgeons of England and have been favourably received by other authorities. It is to be hoped that for the protection of the public steps may soon be taken to regulate by law the administration of anæsthetics and to restrict this important branch of medical practice to persons who are duly qualified to conduct it with safety.

By a recent judgment the House of Lords has finally decided that Section 3 of the Dentists Act imposes on an unqualified person no restriction other than the prohibition to use a title (such as "Dentist" or "Dental Practitioner") implying that he is registered. The clause which other courts had regarded as implying a wider prohibition—namely the prohibition of any claim to be "specially qualified to practise dentistry," whether expressed by the use of a title or conveyed by general words importing personal skill and competence, is now decided to be no more than synonymous with previous clauses, and therefore to be in itself mere surplusage. The Dentists Act has hitherto been thought more stringent than the Medical Act, if not quite so stringent as the law dealing with veterinary practice. But the former Act now proves, when interpreted by the ultimate tribunal, to afford no greater protection to the public against the unqualified practice of dental surgery than the Medical Act affords against the unqualified practice of medicine, and much less than the law confers with regard to the medical treatment of domestic animals. So long as the unqualified person avoids the direct use of certain professional titles, he may use such other misleading descriptions as his ingenuity suggests, and the present law imposes no restraint upon him. On April 1st in the present year the provisions of the Midwives Act came into full operation, and it is now a punishable offence for a woman habitually and for gain to practise midwifery, or to call herself a midwife, unless she is legally certified and enrolled. But any person, however ignorant, may habitually and for gain undertake to practise medicine, surgery, or dentistry, without being required by law to furnish any evidence of his training or skill. The public who resort to him must perforce accept his own statements as to his competency to treat their disorders.

There are not wanting indications that the public are becoming aware of the insufficiency of the existing law. The wide publicity given to the House of Lords' judgment has not been without effect in this direction, so far as concerns the dental branch of surgery. The Report on Anæsthetics has called attention to the unprotected state of the public in another direction. And now I learn with much satisfaction, through Sir Almeric FitzRoy, that arrangements are in progress for the publication, in the form of a Parliamentary paper, of the information on the subject of unqualified medical practice collected by the Local Government Board. That department, we are told, has received a large body of valuable and important evidence in response to the circulars which, at the instance of this Council, it issued to the medical officers of health throughout the country. For the formation of an enlightened public opinion, and, may I add, of an enlightened Parliamentary opinion, an authoritative compilation of the kind now promised is almost a pre-requisite. I trust its publication

will prove to be only the first fruit of the labours of Dr. Langley Browne's Committee on Unqualified Practice.

The experience of the past year or two has taught me that measures are not infrequently introduced into Parliament by private Members which include provisions bearing on the practice of medicine and affecting directly or indirectly the medical interests of the public. Unless, however, these measures attract attention in the public press they are apt to escape notice, even in cases where it is highly expedient that the Medical Council should be cognisant of their terms. By the courtesy of the Privy Council Office and of the Colonial Office we are now usually notified of measures having this character that are introduced under Government authority, and I have reason to believe that such representations as the Council has thought fit to offer on these have received careful consideration by the officials concerned. In order that the like opportunity should be afforded you in the case of private Members' proposals I have endeavoured to get the Council placed on the list of institutions to which copies of all Bills ordered to be printed are regularly sent from the Vote Office. Through the kind mediation of Mr. G. H. Radford, M.P., this privilege has been granted to the Council, and all Bills are now forwarded to the Registrar as they are printed. Members may at any time consult the file which will henceforth be preserved in the office for the information of the Council. In your name I have tendered to Mr. Radford the Council's thanks for the service he has thus rendered us.

With reference to the Charter sought for by the British Medical Association, there is reason to believe that the objections to some of its proposals, which were formulated by our legal advisers, have been held deserving of consideration by the authorities. The Council will receive due notice from the Privy Council should any formal steps in relation to the further progress of the Charter be decided upon.

A considerable proportion of our time at this session will, I regret to say, be occupied by inquiries into charges against registered practitioners. Some have been convicted of offences against the law; others are complained of by public bodies, including the British Medical Association, for conduct which is alleged to be unworthy of professional men. In view of the fact that the Council now includes several new members, it will be necessary for me to repeat a warning already given at the suggestion of our legal advisers—namely, that those who are members of the Association, or of any other body at whose instance complaints are brought before the Council, should take no part in the hearing or determination of the charges in question.

Dr. LITTLE moved that the President should be thanked for his address and that it should be printed in the minutes.

Dr. NORMAN MOORE seconded, and the motion was agreed to with acclamation.

Address to the King.

The PRESIDENT moved that a humble address to His Majesty the King should be framed expressing the loyal feelings of the Council, and should be transmitted to His Majesty through the Secretary of State for the Home Department.

The motion was unanimously agreed to.

Yearly Tables of Examinations.

On the motion of Dr. D. C. MCVAIL the following yearly tables for 1909 were received:—(*a*) I. and II. tables showing results of professional medical examinations; (*b*) table showing results of professional examinations for qualifications in Sanitary Science, Public Health, or State Medicine; (*c*) table showing results of professional dental examinations; (*d*) table showing results of preliminary examinations; (*e*) answers sent by the medical authorities as to the exemptions granted by them in any part of their examinations during the year; (*f*) table showing results of competition held in January, 1910, for commissions in the Indian Medical Service.

At the instance of Dr. MCVAIL a motion was carried conveying to the Under Secretary for India the thanks of the Council for the returns which he had again furnished to it, and requesting that these returns might continue to be furnished to it.

Registration of Qualifications of Prince Edward Island.

The Council then considered a report of the Executive Committee in reference to the medical qualifications granted in Prince Edward Island. This report was made in pursuance of the standing order that—

> The Executive Committee shall be empowered to take the necessary steps for carrying into effect the clauses of the Medical Act, 1886, relating to the registration of the diplomas of colonial and foreign practitioners, and shall report to the Council from time to time their proceedings thereon.

The Executive Committee reported that—

> Part II. of the Medical Act (1886) having been extended by an Order in Council to the Province of Prince Edward Island, they have considered the conditions under which medical qualifications granted in the Province shall be recognised for registration in the Colonial List of the Medical Register of the United Kingdom, and adopted the following resolution:—
>
> That any person who holds the licence of the Medical Council of the Province of Prince Edward Island, granted after examination in medicine, surgery, and midwifery, together with the licence to practise in the Province, shall be entitled to be registered in the Colonial List of the Medical Register, provided he satisfies the registrar of the General Medical Council regarding the other particulars set forth in Part II. of the Medical Act, 1886.

The PRESIDENT, in moving that the report should be received and entered in the minutes, said that when the Order in Council was passed the Province of Prince Edward Island had only a four years' medical curriculum. The Council had sent a communication pointing out that five years were required by it. With laudable celerity the Provincial Council of Prince Edward Island met and passed an Act making five years the period of the curriculum. On that the Provincial Council was to be congratulated.

Sir JOHN MOORE seconded.

The motion was agreed to.

Unqualified Medical Practice.

On the motion of Dr. NORMAN MOORE correspondence between the registrar and Sir Almeric FitzRoy, clerk of the Privy Council, on the subject of unqualified medical practice was placed on the minutes. In the first letter Mr. H. E. Allen, the registrar, wrote asking that the results of the inquiries made by the Local Government Board through medical officers of health on this subject should be communicated to the General Medical Council. Sir Almeric FitzRoy replied in the following terms:—

> Referring to your letter concerning the results of the inquiries made by the Local Government Board on the subject of unqualified medical practice, I have to state, for the information of the General Medical Council, that a large body of valuable and important evidence has been received by the Local Government Board in response to the circulars issued by them to the medical officers of health, and that arrangements are now in progress for the publication, in the form of a Parliamentary paper, of such parts of the information collected as may be found expedient.

Dr. LANGLEY BROWNE moved that the thanks of the Council should be conveyed to the Local Government Board for its action in this matter.

Dr. LATIMER seconded. He said that the time seemed very opportune for further steps to restrict the evils which were going on in connexion with unqualified practice. These he detailed, pointing out also that legislation of late years had been increasingly tending in the direction of protecting the public in matters of health. Nevertheless medicines of the most potent kind were sold to the public, and no action was taken to provide that the contents were declared on bottles and wrappers to be most dangerous. He trusted that when the attention of the Government was called to this matter, and the Members of the Legislature were convinced by the mass of evidence that was now being brought forward of the existing evils, this branch of unqualified and illegitimate practice would be restricted. He hoped that the public would not be allowed to buy the fraudulent medicines issued by quacks. At any rate, labels ought to be affixed to the bottles to show what the contents were, so that the public might be informed of what was wholesome and what was not. The President had told the Council how under the state of the law it was impossible to restrict unqualified practice. All the members of the Council were familiar with the evils caused by the practice of unqualified people. He did not hesitate to condemn in the strongest manner the practice of the so-called medical herbalists. They had a sort of pseudo-sanction for their work. It was a fact that they did not confine themselves to herbal mixtures. He hoped that these people would be hit, as their practice was extremely injurious to the public. It was most desirable to restrict, and if possible to abolish, unqualified practice. He was glad that the Privy Council had been so ready in its response. There would be no difficulty in increasing the

mass of evidence against unqualified practice, and he sincerely hoped that the Legislature would see fit to restrict the sale of the so-called remedies to which he had alluded, and also the practice of people who possessed no proper medical qualification.

The motion was agreed to.

The Revision of the Medical Register.

A report from the Registrar dealing with the steps taken for the revision of the Medical Register in 1909 was received and entered in the minutes.

Mr. ALLEN, the Registrar, explained to the Council the main features of the report.

Delegation of Powers in Penal Business.

The Council received *in camerâ* a report from the Executive Committee in regard to the delegation of powers in penal business.

Appointment of Committees.

The following committees were appointed :—

Executive Committee : Dr. Norman Moore, Sir Henry Morris, Mr. Tomes, Dr. Langley Browne, Sir John Batty Tuke, Dr. McVail, Sir John Moore, and Sir Charles Ball.

Pharmacopœia Committee : The President, Dr. N. Moore, Dr. Barrs, Sir J. Moore, Sir George Philipson, Sir Thomas Fraser, Sir William Whitla, Dr. McVail, and Dr. Caton.

Finance Committee : Mr. Tomes, the President, Sir H. Morris, Sir J. B. Tuke, and Dr. Little.

Dental Committee : The President, Sir H. Morris, Mr. Tomes, Mr, Hodsdon, and Sir Thomas Myles.

Dental Education and Examination Committee : The President, Mr. Tomes, Sir H. Morris, Dr. Knox, Dr. Finlay, Sir Thomas Myles, and Sir Charles Ball.

Students' Registration Committee : Dr. N. Moore, the President, Dr. Adye-Curran, Sir J. B. Tuke, Sir Christopher Nixon, Dr. Mackay, and Dr. Mann.

Penal Cases Committee : The President, Dr. Saundby, Mr. Tomes, Dr. Finlay, and Sir Christopher Nixon.

The Council adjourned.

WEDNESDAY, MAY 25TH.

The Council spent the whole of the sitting to-day in the disposal of penal business.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated :—

Surgery.—F. F. L. How (Section II.) and J. C. Johnson (Section I.), Middlesex Hospital; A. Y. Massey (Section I.), Toronto and University College Hospital; and A. R. Wade (Sections I. and II.), St. Bartholomew's Hospital.
Medicine.—J. A. Laughton (Section II.), Charing Cross Hospital; J. G. Reidy (Section I.), London Hospital; and F. C. V. Thompson (Sections I. and II.), Guy's Hospital.
Forensic Medicine.—J. A. Jones, Manchester; O. Marshall, University College Hospital; E. Newhouse, Leeds; and J. G. Reidy and G. W. Simpson, London Hospital.
Midwifery.—E. Newhouse, Leeds.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: F. F. L. How, J. A. Jones, E. Newhouse, G. W. Simpson, and A. R. Wade.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following candidates have passed the Final Examination for the Licence in Dental Surgery :—

E. R. Black, C. A. Furness, H. Kirk, J. M. Sherin, W. Stewart, and O. Trigge.

The following have passed in Group A of the First Dental Examination :—

A. C. Gordon, S. N. Manning, W. J. Marmion, A. W. Mooney, J. J. Murphy, G. Sheedy, and A. C. Wiley.

The following have passed in Group B of the First Dental Examination :—

L. E. Egan and W. F. Watson.

THE DRAINAGE OF BUDLEIGH SALTERTON.—At a meeting of the Budleigh Salterton urban council held on May 17th it was decided to apply to the Local Government Board for sanction to borrow £9700 for a drainage scheme for the town.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—Mr. Henry Gregg Sherlock, F.R.C.S. Irel., has been elected Professor of Dentistry to the College.

ROYAL DENTAL HOSPITAL.—The Royal Dental Hospital, Leicester-square, has received a legacy of £1000 by the will of the late Mrs. Elizabeth Cooper, per Mr. John H. Hale, the sole executor.

THE SEWERAGE OF FROME.—A Local Government Board inquiry was held at Frome on May 19th into the application of the urban district council to borrow £7000 for purposes of a sewage disposal scheme for Frome.

SOCIETY FOR TRAINING TEACHERS OF THE DEAF AND FOR THE DIFFUSION OF THE "GERMAN" (PURE ORAL) SYSTEM.—The annual general meeting of this society, postponed from May 25th, will be held on Wednesday, June 22nd, by the kind permission of Mrs. Herbert Fletcher, at 20, Devonshire-place, Portland-place, W., at 3.30 P.M.

THE NEWTON ABBOT BOARD OF GUARDIANS AND ARTIFICIAL TEETH.—At a meeting of the Newton Abbot board of guardians held on May 18th, it was decided to allow a female inmate of the workhouse, who had had the whole of her teeth removed by the advice of the medical officer, and who was willing to leave the institution and earn her living, a set of artificial teeth. The cost was not to exceed 4 guineas.

THE BRISTOL EYE HOSPITAL.—At a recent meeting of the friends of the Bristol Eye Hospital it was decided to hold the centenary fête of this institution at the Zoological Gardens, Clifton, on June 15th and three following days. It is hoped that a satisfactory sum will be raised for the hospital, as the expenditure exceeds the income by about £500 per annum, and funds are also required for an extension of the out-patient department.

DR. DOYEN'S LECTURES.—On Saturday, May 14th, Dr. Doyen brought to an end his course of lectures on descriptive anatomy in its relations to surgical technique. At this last lecture, which was, in a way, a recapitulation of the course, together with an exhibition of magnificent anatomical sections thrown on the screen, a large crowd attended, but one which this time was perfectly attentive and respectful. Among those present were M. Mirman, Director of the Department of Hygiene and Medicine at the Ministry of the Interior, and M. Mesureur, the Director-General of the Assistance Publique, both of whom expressed much astonishment at the new methods of demonstration put forward by the lecturer. Dr. Doyen will from June 13th to 18th give another course of six lectures upon the processes of immunity, with lantern slides showing the details of phagocytosis. These lectures will take place in the same conditions as the former ones and at the same place. There has therefore been started in Paris a course of medical teaching, eminently interesting, to which there is free entry for all students as well as for French and foreign medical men.

THE MEDICAL DEFENCE UNION.—The annual general meeting of the Medical Defence Union was held at the Royal Station Hotel, Hull, on May 19th. Before formally opening the meeting, the President, Mr. Stamford Felce, stated that it had been duly considered as to whether the date of the meeting should be postponed in consequence of the death of His Majesty King Edward VII. It was, however, decided that as the business was purely statutory there was no necessity for such alteration of date. Before carrying out the agenda the President moved a resolution of respectful sympathy with the Queen-Mother in the great loss which Her Majesty, the Royal Family, and the United Empire had suffered. This was carried silently, the members upstanding. The President, after the minutes had been confirmed, gave an address upon the disabilities of medical practice, and the absolute necessity for every registered practitioner to avail himself of the protection afforded by the Medical Defence Union and kindred societies. The annual report was then presented and, being approved by the meeting, was ordered to be entered upon the minutes. The usual statutory resolutions were passed, and Mr. Stamford Felce, Mr. T. Gunton Alderton, and Mr. M. Hallwright were re-elected members of

the council. After a vote of thanks to the President and Council for their work, the meeting terminated.

RESEARCH DEFENCE SOCIETY.—The annual general meeting of this society will be held on Friday, June 3rd, at 5 o'clock, in the library of the Royal College of Physicians of London. The chair will be taken by Lord Cromer, the president of the society.

Dr. F. W. Andrewes will deliver the Croonian lectures on Tuesdays and Thursdays, June 14th, 16th, 21st, and 23rd, at 5 o'clock, at the Royal College of Physicians of London. Subject, "The Behaviour of the Leucocytes in Infection and Immunity."

THE TRURO BOARD OF GUARDIANS AND THE MIDWIVES ACT.—At a meeting of the Truro board of guardians held on May 18th it was decided to allow a fee of 1 guinea to the district medical officers who were called by midwives in cases of emergency, but it was also determined that before applying to the guardians for these fees the medical officer should be asked to make a reasonable offer to obtain the fee from the person attended by him.

UNIVERSITY OF OXFORD.—The Board of Faculty of Medicine gives notice that the examination for the Diploma in Ophthalmology will be on July 19th, 20th, and 21st, and not as previously advertised.—Harold Scurfield, M.D. Edin., D.P.H. Camb., has been elected an examiner for the Diploma in Public Health. For the Diploma in Ophthalmology Edward Treacher Collins, F.R.C.S. Eng., and John B. Lawford, F.R.C.S. Eng., have been appointed examiners.—The following change in the regulations relating to the examination for the degree of B.M., B.Ch. will come into effect in Michaelmas term, 1910: Instead of the certificate hitherto required, one will be required signed by the medical officer of a lying-in hospital or the lying-in wards of a general hospital showing that the candidate has either (1) regularly attended the indoor practice of a lying-in hospital or the lying-in wards of a general hospital for a period of three months, and after having received therein practical instruction in the conduct of labour, under the personal supervision of the medical officer, has conducted 20 cases of labour under official medical supervision; or (2) given daily attention during one month, upon the indoor practice of a lying-in hospital or the lying-in wards of a general hospital, and has therein conducted cases under the personal supervision of a medical officer of the hospital, by whom, having been adjudged competent, he has been authorised to attend, and has attended, not less than 20 cases of labour under official medical supervision. To the medical officer who signs this certificate the candidate must produce evidence that, prior to the course certified, he has acted as surgical dresser for six months and has acted as clinical medical clerk for a like period, and has attended a course of instruction in midwifery.

THE BRITISH MEDICAL BENEVOLENT FUND.—On May 26th a drawing-room meeting was held at the house of Sir Alfred Fripp for the purpose of calling attention to the work of the Guild of the British Medical Benevolent Fund. Mr. H. Cosmo Bonsor, chairman of Guy's Hospital, presided, and there was a large attendance of ladies. Mr. S. O. Buckmaster, K.C., in moving the first resolution, "That this meeting pledges itself to do its utmost to support the objects of the British Medical Benevolent Fund Guild," said that the Guild endeavoured by personal sympathy to assist a class of men who had benefited everybody. The medical profession stood by itself, although there was no great trouble or sorrow that those men were not called in to witness and to share. Few more pathetic things could be imagined than the anxiety and suspense with which in face of some impending trouble people hung upon the lips of the doctors, asking them to do what was often impossible—to set back the hand of the clock, to check the progress of fatal illness, and to arrest the sure and certain foot of death. Such demands, though extravagant, never failed to meet with a ready response, and if that was true concerning those who lived in the West-End, it was much truer of the vast area of society of which the West-End formed only a very small, even though it was a glittering, part. The foot of the medical man was never so fleet as when it ascended the staircase of a poor man's home. They should always judge a profession by the best which it produced, firstly, because it showed what the profession was capable of producing, and secondly, because the standard of the best man was the standard to which all would try to attain. Judged by that standard there was no profession in the world which was comparable to the practice of medicine. It was a great privilege that doctors possessed to be able in the pursuit of their livelihood to bring comfort and happiness to the people with whom they were brought into contact. But the struggle was a hard one for many, and rendered additionally difficult, and to his mind additionally terrifying, by the fact that, no matter what the circumstances might be, appearances had to be kept up. Mrs. Finn, in seconding the resolution, referred to the difficulties under which medical missionary work was started in Jerusalem with the small sum of £10. That work had grown very rapidly, however, and she exhorted her listeners not to be discouraged by reason of lack of funds at the commencement. The resolution on being put to the meeting was carried unanimously. Sir Alfred Fripp apologised for the absence of Dr. Russell Wakefield, dean of Norwich, and Dr. Arthur Latham, who had been prevented from attending the meeting. He was glad to say that owing to such publicity as the movement had already received an annuity of £20 had been promised, and two subscriptions of £10 10*s.* and smaller sums had also been received. Dr. S. West said that he hoped that this meeting would be the first of a series of drawing-room meetings. Guy's Hospital was to-day represented by Mr. Bonsor, and he trusted that all the London hospitals would take part in the work. He always told his students when addressing them on general matters that they had two great duties to perform, the one being to insure themselves, and the other to pay the debt which they owed to their less fortunate brethren. It was their duty to subscribe to a benevolent society. Lady Tweedy then proposed a vote of thanks to Sir Alfred and Lady Fripp for their kindness in putting their drawing-room at the disposal of the society, and the meeting terminated.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ASH, EDWIN, M.D. Lond., has been appointed Assistant Physician to the Italian Hospital, London.

BURTON, W. R., L.R.C.P. & S. Irel., has been appointed District Medical Officer to the Spalding Union.

BUTT, H. T. H., M.B., B.C. Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant Medical Officer to the Randfontein Estates Gold Mining Company, Randfontein, Transvaal.

DIXON, T. BENJAMIN, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Bristol Dispensary.

GILLESPIE, W. J., L.S.A., has been appointed District Medical Officer to the Poplar Borough Parish.

HARRIS, JOHN HENRY, M.D. Durh., M.R.C.S., L.S.A., D.P.H. Camb., has been reappointed Medical Officer of Health for the Dartmouth and Totnes (Devon) Port Sanitary Authority.

HERAPATH, CHARLES EDWARD KYNASTON, M.B., B.S. Lond., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Bristol Dispensary.

LANDER, H. W. G., M.B., C.M. Edin., has been appointed District Medical Officer to the Bakewell Union.

O'MEARA, W. H., M.R.C.P., L.R.C.S. Irel., has been appointed one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Carlow.

PASSMORE, J. E. S., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Gainsborough District of the county of Lincoln.

POLLARD, REGINALD, M.B. Durh., D.P.H., M.R.C.S., has been appointed Honorary Anæsthetist to the Metropolitan Throat and the Royal National Orthopædic Hospitals.

ROBERTS, CHARLES, M.B., B.S. Lond., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Honorary Assistant Surgeon to the Manchester Royal Infirmary.

SCRASE, J. J. S., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer to the Newton Abbot Union.

SHARP, P. J., M.B., C.M. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Blackford District of the county of Perth.

SMITH, J. W., F.R.C.S. Eng., has been appointed Honorary Surgeon to the Manchester Royal Infirmary.

SOMERVILLE, H., L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer to the Bedford Union.

TONGE-SMITH, W., M.D. Aberd., D.P.H., has been appointed District Medical Officer to the Pocklington Union.

TREVOR-ROPER, B. W. E., L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer to the Alnwick Union.

WADE, CHARLES, L.R.C.P. Lond., M.R.C.S., has been appointed Surgeon to the Boscastle (Cornwall) Friendly Society.
YOUNG, ERNEST, M.D. Durh., has been appointed Honorary Physician to the Farringdon General Dispensary.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ABERDEEN ROYAL INFIRMARY.—Anæsthetist.
ALBERT DOCK HOSPITAL, Connaught-road, E.—Senior House Surgeon. Salary £75 per annum, with board, residence, and washing. Also House Surgeon. Salary £50 per annum, with board, residence, and washing.
BENENDEN SANATORIUM.—Assistant Medical Officer, unmarried. Salary £80 per annum, with board, lodging, and laundry.
BETHLEM HOSPITAL.—Two Resident House Physicians, unmarried, for six months. Salary at rate of £25 each per quarter, with board and washing.
BEVERLEY, EAST RIDING LUNATIC ASYLUM.—Second Assistant Medical Officer, unmarried. Salary £150 per annum, with board, apartments, and washing.
BIRMINGHAM AND MIDLAND HOSPITAL FOR SKIN AND URINARY DISEASES, Birmingham.—Clinical Assistant for three months. Salary at rate of 52 guineas per annum.
BRECKNOCK COUNTY AND BOROUGH INFIRMARY.—Resident House Surgeon, unmarried. Salary £120 per annum, with apartments, board, attendance, &c.
BRISTOL, HAM GREEN FEVER HOSPITAL.—Resident Medical Officer. Salary £200 per annum, with board, rooms, and attendance.
BRISTOL ROYAL INFIRMARY.—Honorary Medical Registrar.
BRIXTON DISPENSARY, Water-lane, S.W.—Resident Medical Officer, unmarried. Salary £150 per annum, with apartments, attendance, coal, and gas.
BURY INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, residence, and laundry.
BUXTON, WYE HOUSE ASYLUM.—Assistant Medical Officer. Salary £120 per annum.
CARDIFF INFIRMARY (GENERAL HOSPITAL).—House Surgeon; also House Surgeon for Ophthalmic and Ear and Throat Departments, each for six months. Salary £30, with board, residence, and laundry in each case.
CHEADLE, MANCHESTER ROYAL INFIRMARY CONVALESCENT HOSPITAL.—Assistant Medical Officer, unmarried, for six months. Salary at rate of £80 per annum, with board and residence.
CHELMSFORD, ESSEX EDUCATION COMMITTEE.—School Medical Officer. Salary £350 per annum.
COVENTRY AND WARWICKSHIRE HOSPITAL.—Junior House Surgeon. Salary £80 per annum, with rooms, board, washing, and attendance. Also Honorary Aural Surgeon.
DERBYSHIRE ROYAL INFIRMARY.—Honorary Assistant Physician.
EAST BENGAL, BAPTIST MISSION HOSPITAL.—Locum Tenens, unmarried. Salary £120 per annum, house accommodation, and travelling expenses.
EVELINA HOSPITAL FOR CHILDREN, Southwark, S.E. — House Physician.
GLOUCESTERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board, residence, and washing.
GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—Assistant House Surgeon. Salary £50 per annum, with board, residence, and laundry.
HEMEL HEMPSTEAD, WEST HERTS HOSPITAL. — House Surgeon. Salary £100 per annum, with rooms, board, and washing.
HOSPITAL FOR EPILEPSY AND PARALYSIS AND OTHER DISEASES OF THE NERVOUS SYSTEM, Maida Vale, W.—Resident Medical Officer for six months. Salary at rate of £50 per annum, with board, lodging, and washing.
HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—Assistant Casualty Medical Officer, unmarried, for six months. Salary £30, with board, residence, and washing. Also House Surgeon and House Physician, early in July.
HULL, ROYAL INFIRMARY.—Casualty House Surgeon for six months. Salary at rate of £60 per annum, with board and lodging.
INDIAN MEDICAL SERVICE, India Office, London.—Fifteen Commissions in His Majesty's Indian Medical Service.
ITALIAN HOSPITAL, Queen-square, London, W.C.—House Surgeon for six months. Salary £60 per annum, with board and residence.
KENDAL, WESTMORLAND CONSUMPTION SANATORIUM.—Assistant Resident Physician, unmarried. Salary £100 per annum, with residence, board, &c.
LEICESTER BOROUGH ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £160 per annum, with board, apartments, and washing.
LEICESTER INFIRMARY.—Second House Surgeon. Salary at rate of £100 per annum, with board, lodging, and washing. Also Assistant House Surgeon. Salary at rate of £60 per annum, with board, lodging, and washing.
LIVERPOOL STANLEY HOSPITAL.—House Surgeon for two months. Salary 2 guineas per week.
MANCHESTER ROYAL INFIRMARY.—Assistant Surgical Officer. Salary £35 per annum.
MANCHESTER WORKHOUSE, Crumpsall.—Junior Resident Assistant Medical Officer, unmarried. Salary £110 per annum, with apartments, washing, &c
MIDDLESBROUGH, NORTH RIDING INFIRMARY.—Assistant House Surgeon. Salary £75 per annum, with board, residence, and washing.
MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood, Middlesex.—House Physician at Northwood. Salary £75 per annum, with board, residence, and washing.
NOTTINGHAM GENERAL HOSPITAL.—Assistant House Surgeon. Salary £60 per annum, with board, lodging, and washing.
PADDINGTON, PARISH OF.—District Medical Officer and Public Vaccinator. Salary £100 per annum.
QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—Two House Surgeons and House Physician for six months. Salary at rate of £60 per annum each, with board, residence, and washing.
REDHILL, EARLSWOOD ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £130 per annum, with board, lodging, and washing.
RENFREW, COUNTY COMMITTEE ON SECONDARY EDUCATION.—School Medical Inspectors for No. 1 and No. 2 Districts. Salaries £300 per annum.
ROYAL EAR HOSPITAL, Soho.—Honorary Assistant Anæsthetist.
ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN.—Junior Resident Medical Officer. Salary at rate of £40 per annum, with board and washing.
RYDE, ROYAL ISLE OF WIGHT COUNTY HOSPITAL.—Resident House Surgeon. Salary £125 per annum.
ST. ANDREWS UNIVERSITY.—Examiners in Faculty of Medicine and Faculties of Science and Medicine.
ST. MARYLEBONE INFIRMARY, Rackham-street, Ladbroke Grove-road, Notting Hill, London, W.—Medical Superintendent. Salary £450 per annum, with unfurnished house, gas, coals, and washing.
SALFORD UNION INFIRMARY.—Resident Assistant Medical Officer. Salary £120 per annum, with furnished apartments, attendance, and rations.
SALISBURY, FISHERTON HOUSE ASYLUM.—Assistant Medical Officer, unmarried. Salary £150 per annum, with board, washing, lodging, &c.
SALISBURY INFIRMARY.—Assistant House Surgeon, unmarried. Salary £50 per annum, with apartments, board, lodging, and washing.
SCARBOROUGH HOSPITAL AND DISPENSARY.—Junior House Surgeon for six months. Salary £80 per annum, with board, residence, and laundry.
SHEFFIELD ROYAL HOSPITAL.—Assistant House Surgeon and Assistant House Physician, unmarried. Salary £50 each per annum, with board, lodging, and washing.
SOUTH SHIELDS, INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTOE DISPENSARY.—Junior House Surgeon. Salary £90 per annum, with residence, board, and washing.
SOUTHWARK UNION INFIRMARY, East Dulwich-grove, S.E.—Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing.
STAFFORD, STAFFORDSHIRE GENERAL INFIRMARY.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.
STOCKPORT INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, washing, and residence.
STOKE-ON-TRENT, NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL, Hartshill.—Resident Surgical Officer. Salary £120 per annum, with apartments, board, and washing. Also Junior House Surgeon for six months. Salary at rate of £50 per annum, with board, apartments, and washing.
TAUNTON, TAUNTON AND SOMERSET HOSPITAL.—Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.
UNIVERSITY COLLEGE HOSPITAL, Gower-street, W.C.—Assistant Physician.
UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.—Lecturer in Mental Physiology and Mental Diseases.
VENTNOR, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.—Two Assistant Resident Medical Officers, unmarried. Salary £100 per annum each, with board, lodging, and washing.
WEST LONDON HOSPITAL, Hammersmith-road, W.—House Physician for six months. Board, lodging, and laundry provided.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Linlithgow, in the county of Linlithgow; at Midleton, in the county of Cork; and for the Mottram and Glossop District of the counties of Chester and Derby.

Births, Marriages, and Deaths.

BIRTHS.

AINSLIE.—On May 19th, at Pitfour, Kington, Herefordshire, the wife of Dr. W. Ainslie, of a daughter.
ALCOCK.—On May 18th, at Abbey Gate, St. Catherine's, Lincoln, the wife of Dr. Frank Alcock, of a daughter.
BARNES.—On May 10th, at The Pole, Failsworth, Manchester, the wife of Dr. Ernest Barnes, of a daughter.
PAUL.—On May 14th, at Isledon-road, Finsbury Park, N., the wife of John F. Paul, M.R.C.S., L.R.C.P., of a son.
SUTCLIFFE.—On May 10th, at Dalby-square, Margate, the wife of W. Greenwood Sutcliffe, F.R.C.S. Eng., of a daughter.

MARRIAGES.

BUTT—BENSUSAN.—On May 16th, at the British Consulate, Naples, Geoffrey Crawford Butt to Ruth Bensusan, M.D., B.S.
HALL—COLMAN.—On May 21st, at All Saints' Parish Church, Hove, Donald George Hall, M.A., M.D. Cantab., M.R.C.P. Lond., to Marjorie, only daughter of Jeremiah Colman, J.P., Hove.

DEATHS.

CANE.—On May 20th, at Edmonton, London, Frank E. Cane, L.R.C.P. & S. Edin., D.P.H. Cantab., Divisional Surgeon, Metropolitan Police.
BARTER.—On May 20th, at Greencroft-gardens, N.W., William Barter, M.D.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE PURITY OF FOOD.

WE yield to no one in our concern for the purity and wholesomeness of food supplies, and we doubt whether the promoters of the Pure Food and Allied Trades Exhibition held at the Royal Horticultural Hall, Vincent-square, Westminster, this week have done any service to the cause judging from the obviously exaggerated and incorrect statements which have appeared in the accounts of the exhibition in the daily press and which we suppose were inspired by those connected with the exhibition. As examples we may quote the following:—"Annatto, which at one time figured largely in the adulteration of milk, has now been superseded by cheaper articles such as formaldehyde, peroxide of hydrogen, and fluoric acid." (Annatto, of course, is used to give a yellow creamy colour to the milk and not one of the substances which are said to have superseded annatto would answer the same purpose.) "The peroxide is an article often used by ladies for hair-bleaching purposes, while fluoric acid is of such a biting nature that it cannot be kept in glass bottles, but has to be enclosed in special receptacles made of indiarubber." (We challenge anyone to demonstrate to us that fluoric acid, the substance described as of a "biting nature," is ever added to milk or that milk ever contains it.) "Vinegar which is used in the preparation of cheap sauces and pickles is chiefly composed of sulphuric acid." (We challenge this statement with as much confidence as the previous one.) "Cocoas contain red lead." (We doubt very much whether the slightest proof can be obtained of this.) We welcome the public ventilation of such questions as the addition of preservatives and colouring matters to foods, the chemical bleaching of flour, the contamination of foods by dirty handling and transit, and so forth, but no advance will be made by putting forward statements which are untrue. The imperfections of the Food and Drugs Act are not the fault of the public analyst, but arise chiefly out of the elastic interpretations given to the clauses in the law and the fact that those before whom legal proceedings are taken have in general no technical knowledge.

We have urged again and again the appointment of a court of reference composed of scientific and legal authorities, with whom alone the sound decision of questions involving a knowledge of medicine, physiology, and analysis can be left. The present Food and Drugs Act would then work with much better effect. But as it is, we do not hesitate to say that it requires no amendment whatever to deal with fluoric acid in milk, sulphuric acid as a chief constituent of vinegar, lead or other poisons in confectionery—substances about the harmfulness of which there can be no shadow of a difference of opinion.

AN ARTIFICIAL NAIL.

To the Editor of THE LANCET.

SIR,—I have a patient, a girl, who has had the matrix of her right thumb-nail destroyed, and of course a new nail will not grow. She is naturally very distressed and wants to know if an artificial nail can be provided. Can any of your readers tell me if such things are made and how they are fixed on?

I am, Sir, yours faithfully,

May 18th, 1910. MEDICUS EDIN.

A DEATH FROM LEAD POISONING IN BIRMINGHAM.

IT seems somewhat of an anomaly that in these days of sanitary administration and factory legislation a death from industrial lead poisoning should occur in a city like Birmingham, and the narrative which was unfolded in the *Times* of May 19th raises questions as to how far there is as much coördination between the several officials more or less involved as could be desired. A painter's labourer, whose principal work was to prepare old wheels for the painter by scraping off the old paint, dies from lead poisoning, and at the inquest it transpires, and is admitted by the secretary of the firm, that there was not proper provision for washing, the patient having complained to his wife that as there was no place in the works to wash he had to take his meals with dirty hands. The secretary, asked whether in his opinion the washing of hands in buckets and their drying upon old rags was sufficient provision, replied that this was all that they had possessed for 60 years, and we are glad to see the comment of the deputy coroner that methods which might have sufficed 60 years ago, when there were no Factory Acts and little knowledge as to lead poisoning, were no longer applicable to-day. The secretary to the works stated that he had never received any copy of the Home Office regulations, but it seems to us incredible that an official connected with these works should not have been alive to the possibility of lead poisoning in this case, more especially as the patient had repeatedly expressed the opinion to his wife that he was suffering from lead colic. It is a misfortune that the patient did not apparently seek medical advice, for in this manner the case might have been duly notified to the Chief Inspector of Factories under the provisions of the Factory and Workshops Acts, and the washing accommodation inspected. It would appear that the only means of overcoming this indisposition of the worker to seek medical advice is to provide for periodical medical inspection of the workers, as is so often arranged for in connexion with those engaged in the phosphorus industry. Apparently some reforms have been now introduced into the works in question in consequence of this unfortunate occurrence, but it would be better if reforms such as these could be brought about in some other manner than through deaths. We must not, of course, lose sight of the fact that within recent years there has been an enormous reduction annually in the number of deaths from lead poisoning, but if cases such as this one are to be avoided more coöperation between the sanitary and factory officials is desirable.

AS OTHERS SEE THEMSELVES.

"A new scheme a young German doctor discovered much sickness to cure,
But all our old doctors, so placid, to learn it could never endure.
Was it lost? Not at all; just exported; and when from abroad it came back
Quite unaltered, *then* Germans acclaimed it. Only Germans with us credit lack." —From the *Fliegende Blätter*.

HOVE AND SCHOOL MEDICAL INSPECTION.

THE Hove town council at a recent meeting ratified the proceedings of its education committee, deciding to engage a properly qualified dentist to attend to defective teeth among the school children of the borough at a cost not exceeding £100 per annum for one year, and to provide the necessary equipment at a cost not exceeding £40; to select, as a preliminary step, ten chronic cases of ringworm of the scalp and treat them by the X ray system at an estimated cost of £2 2*s*. each; and to provide a special class for mentally defective children under the Elementary Education (Defective and Epileptic Children) Act, 1899. In the cases of defective eyesight the parents are to provide spectacles themselves, and the local public institutions are to deal with cases of large tonsils and adenoids. Provision has been made at Hove in dealing with parents who are indifferent as regards the health of their children. Dr. L. A. Parry, the school medical officer, has found the coöperation of parents in the subsequent treatment of defects notified to them to be disappointing.

TAKING THE OATH.

To the Editor of THE LANCET.

SIR,—Can you tell me what status a witness has in a court of law as regards taking the oath? Does the new form of taking the English oath supplant the Scots fashion, and has the Act regarding the new English form deprived a witness of his right to insist on taking the Scots oath? Has a judge of any status the power to refuse to allow the Scots oath? I should be very grateful if at an early date you could give answers to these questions in your columns.

I am, Sir, yours faithfully,

May 13th, 1910. J. R.

*** The Oaths Act, 1909, which has introduced a form of taking the oath in a court of justice by holding a Testament in the uplifted hand and repeating a prescribed form of words, does not repeal any other Act or part of an Act, and as far as we are aware Section 5 of the Oaths Act, 1888, is still in force. Under it a witness was given the right to ask to be sworn in the Scotch fashion and to be so sworn without further question. The Act of 1909 was passed to meet the views of those who objected to the kissing of the book, and it was evidently intended to be adopted and followed universally.—ED. L.

ADULTERATION.

A War Office manual regarding military cooking gives some hints to cooks as to articles likely to be adulterated, and some of the quotations are not without humour. For instance, cayenne pepper is said to be often adulterated with brickdust, whilst black and white pepper is much adulterated with meal, clay, grate rubbish, burnt bread, &c. Coarse brown sugar frequently contains sugar mites; and it is extensively adulterated with sand, plaster of Paris, chalk, flour, and maize. Salt is declared to be the only article which it is "almost impossible to adulterate."

SLEEPING SICKNESS.

THE Sleeping Sickness Bureau, which has its headquarters at the Royal Society, has issued an admirable little pamphlet for the use of travellers and residents in tropical Africa, showing how to avoid the infection of sleeping sickness, and giving an account of the glossina palpalis and other biting flies. The pamphlet sets out in plain words how sleeping sickness is caused, how the organism is conveyed from the sick to the healthy, how the glossina palpalis may be distinguished from other blood-sucking diptera, and the best methods of avoiding infection. The account of the fly itself, and of the occasions under which travellers are most liable to be bitten, is supplied by Dr. W. M. Graham, the director of the Medical Research Institute at Lagos. Preventive methods are clearly set forth, and the Sleeping Sickness Bureau asks for any authenticated information

about the life-history and habits of the fly which travellers can supply, remarking that "our knowledge of the life-history of the fly is still very imperfect." The pamphlet should be in the hands of every traveller who goes to South Africa or tropical Africa or the south-west corner of Arabia, which are the districts where the glossina lives, and applications for copies should be addressed to the Director, Sleeping Sickness Bureau, Royal Society, Burlington House, London, W.

THE PREPARATION OF TEA.

ONE factor that does not count for abstinence from alcohol is the invariably long time which is taken to prepare tea. In the way of providing a stimulant nothing can be quicker than supplying a half pint of beer or a glass of, say, whisky-and-soda. When, however, tea is the stimulant ordered there is considerable time occupied in getting it ready for reasons which it is difficult to see. Boiling water is, or should be, available at most places of public refreshment, yet when tea is ordered it would seem that some machinery is involved; the tea, at all events, is a long time coming, a process has to be gone through which inordinately detains the customer. This delay is a source of inconvenience, in particular to travellers, whether they travel by rail, motor or cycle, or on foot, and the temptation is to save time by ordering an alcoholic drink, which is served promptly. The moral is obvious.

THE DUTIES OF A PUBLIC VACCINATOR.

To the Editor of THE LANCET.

SIR,—Will you kindly answer the following? Can a public vaccinator vaccinate a child under three months, enter it in his register, and charge accordingly? I am, Sir, yours faithfully,

May 19th, 1910. T. L. ASHFORTH.

*** A public vaccinator is obliged to attend and vaccinate any child, whether it be under three months old or not, if requested by the parents to do so; he is obliged to enter the proceeding on his register and is entitled to charge the work to the vaccination authority. Further, under the amended order of Jan. 27th, 1910, and various orders of 1907, the vaccination officer is instructed to communicate with the parents of all unvaccinated children when they attain the age of three months.—ED. L.

THE NORTH WALES TEMPERANCE FEDERATION.

THIS body is issuing a manifesto, signed by 101 medical practitioners in North Wales, upon the Use of Alcoholic Drinks. The manifesto is an appeal to all medical men in North Wales to recognise that "what is considered to be a moderate use of alcohol" does not promote health, and asks them "especially not to give, or even seem to give, the sanction of their professional authority to any general employment of alcoholic drinks in cases of disease."

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

WEDNESDAY.

SPECIAL MEETING OF FELLOWS OF THE SOCIETY at Morley Hall, George-street, Hanover-square, W.: at 5 P.M.

Discussion:

On Vaccine Therapy, its Administration, Value, and Limitations (Third Meeting). Re-opened by Dr. William Bulloch, and continued by Sir William B. Leishman, Sir John McFadyean, Professor R. T. Hewlett, Mr. K. W. Goadby, Dr. J. Henderson Smith, Dr. Arthur Whitfield, Dr. John Freeman.

FRIDAY.

LARYNGOLOGICAL SECTION (Hon. Secretaries—George C. Cathcart, L. Hemington Pegler): at 5 P.M.

Cases and Specimens.

ELECTRO-THERAPEUTICAL SECTION (Hon. Secretaries—Reginald Morton, G. Harrison Orton): at 8.30 P.M.

Annual General Meeting. Election of Officers and Council for Session 1910–11.

Paper:

Dr. Joseph Bolton: The Relief of Symptoms of Prostatic Obstruction by Electrical Treatment.

Discussion:

On the Relative Value of Various Types of High Tension Transformer (including Coil) used for the Production of X Rays (opened by Dr. Reginald Morton).

SATURDAY.

OTOLOGICAL SECTION (Hon. Secretaries—Hunter F. Tod, H. J. Marriage) at 11, Chandos-street, W., at 10 A.M.

Paper:

Dr. Wyatt Wingrave: Notes on the Pathology of Cholesteatoma.

Cases and Specimens:

Mr. A. L. Whitehead: Temporo-sphenoidal Abscess; Vomiting entirely Absent.

Dr. P. H. Abercrombie and Dr. Dan McKenzie: Hysterical Deafness with Active Vestibular Reactions.

Dr. H. J. Davis: Deformity of Both Pinnæ Resulting from Perichondritis following Double Mastoid Operation.

Dr. Hunter Tod: (1) Exostosis of Right External Meatus; (2) A Case in which the Clinical Symptoms Simulated a Cerebellar Abscess; (3) Cholesteatoma or Keratosis Obturans of the External Auditory Canal.

Mr. George Wilkinson: Two Cases of Cholesteatoma of Unusual Size.

Dr. P. Watson Williams: Myelogenous Sarcoma of the Right Temporal Bone with Extension through the External Meatus, Resembling an Aural Polypus.

Mr. G. J. Jenkins: Fracture of the Temporal Bone.

RONTGEN SOCIETY, 20, Hanover-square, W.

THURSDAY.—8.15 P.M., Dr. H. Pirie: Practical Observations on Everyday X Ray and Electrical Work; Filtration of Rays; Measurement of Rays; Rapid Stereoscopic Methods, &c. (with lantern).—Dr. R. Knox: Recent Improvements in Radiographic Technique (with lantern).—Dr. Hampson will show a New Form of Apparatus for Producing Rythmical Variations in the Strength of Electrical Currents.

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's Hospital, Tottenham, N.

THURSDAY.—4.15 P.M., Clinical Meeting.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. W. Evans: Clinique (Skin). 5.15 P.M., Lecture:—Dr. R. Russell: Diagnosis of Disseminated Sclerosis.

TUESDAY.—4 P.M., Dr. F. J. Wethered: Clinique (Medical). 5.15 P.M. Lecture:—Dr. C. Mercier: Demonstration of Mental Cases.

WEDNESDAY.—4 P.M., Mr. A. H. Tubby: Clinique (Surgical). 5.15 P.M. Lecture:—Dr. W. H. C. Greene: On the Treatment of Certain Fractures.

THURSDAY.—4 P.M., Dr. O. K. Williamson: Clinique (Medical). 5.15 P.M.. Lecture:—Mr. T. Walker: The Diagnosis and Treatment of Papilloma of the Bladder.

FRIDAY.—4 P.M., Mr. C. Worth: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Dunn: Ocular Symptoms in General Disease.

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 11.30 A.M., Demonstrations in Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Low: Sleeping Sickness.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Dr. Beddard: Practical Medicine. (Lecture II.)

THURSDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Bidwell: Surgery of Gastric Ulcer.

FRIDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. Medical Registrar: Demonstration of Cases. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Saunders: Clinical (with Cases).

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Diseases of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. Howell Evans), 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. W. Carson).

TUESDAY.—Clinic: 10 A.M., Medical Out-patient (Dr. A. G Auld). 2.30 P.M., Operations. Clinics:—Surgical (Mr. W. Edmunds); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting). 4.30 P.M., Demonstration:—Dr. Meachen: Selected Skin Cases.

WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Dr. A. H. Pirie).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel).

FRIDAY.—10 A.M., Clinic:—Surgical Out-patient (Mr. Howell Evans). 2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie).

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye. 2.15 P.M., Special Lecture:—Dr. F. Taylor: Tremors and Convulsive Movements.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 3.15 P.M., Special Lecture:—Mr. McGavin: The Surgery of Urethral Stricture.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4 P.M., Lecture:—Dr. M. Bruce: Aortic Incompetence and its Clinical Lessons.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY.—3.45 P.M., Lecture:—Dr. Atkinson: Pharynx, and Naso-pharynx.

FRIDAY.—3.45 P.M., Lecture:—Dr. Abercrombie: Clinical Cases.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY AND FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. J. Taylor: Eye Signs and Symptoms in Nervous Disorders.

HOSPITAL FOR SICK CHILDREN (UNIVERSITY OF LONDON), Great Ormond-street, W.C.

THURSDAY.—4 P.M., Lecture:—Dr. Hutchison: Hysteria in Childhood.

MANCHESTER ROYAL INFIRMARY.

TUESDAY AND FRIDAY.—4.30–5.30 P.M., Honorary Staff: Post-Graduate Clinical Demonstration (Medical, Surgical, and Special Departments).

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (30th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.),

TUESDAY (31st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

WEDNESDAY (1st).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (2nd).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (3rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (4th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 35, Rue Franklin, Asnières, Paris.

Three Clinical Lectures

Delivered at the Middlesex Hospital

BY SIR HENRY MORRIS, M.A., M.B. LOND., F.R.C.S. ENG.,

EMERITUS LECTURER ON SURGERY IN THE MEDICAL SCHOOL.

LECTURE II.[1]

Delivered on March 1st.

ON A CASE OF ANEURYSMAL VARIX IN THE LEG OF A CHILD, AGED 7 YEARS.

GENTLEMEN,—On August 24th, 1761, two persons then holding appointments in this hospital entered into the ranks of the Immortals. One was Dr. William Hunter. Thirteen years before this date—namely, in 1748—the year after he became a member of the Corporation of Surgeons, Dr. Hunter had been elected "one of the surgeon men-midwives," as the office was then styled, to the hospital. The other was Mr. Thomas Brookhouse Cheshire, who, in this the first year of his celebrity (1761), was "a servant in the laboratory at the Middlesex Hospital."

WILLIAM HUNTER AS A SCIENTIFIC WORKER.

Quite independently of the particular claim to immortality to which I am referring, William Hunter, by the work he accomplished both before and after this eventful occasion, gained a reputation so great as to make his name for ever illustrious in the records of our profession. He is celebrated as the founder of the first important anatomical school in London and as the greatest benefactor of the museum of the University of Glasgow; also as the collector of the most magnificent treasure of Greek and Latin books that had been accumulated by any person since the days of the renowned Dr. Mead; and further, as the author of "The Anatomy of the Gravid Uterus," which he published in 1775, after he had worked at the subject for 24 years.

Dr. William Hunter was a celebrated physiologist in his time, and the first great teacher of anatomy in England. He was appointed professor of anatomy at the Royal Academy of Arts on its inauguration in 1768. He anticipated by 60 years what was written by the brilliant Bichat on the structure and arrangement of synovial membranes. He is remembered, too, on account of his famous disputes with the Monros of Edinburgh as to whom belongs the merit of having been the first to point out the origin and use of the lymphatics, the power of absorption by the veins, the permeability to injections of the tubuli testis, and the presence of ducts in the lacrymal gland of man; on account, too, of his controversy as to whether Percival Pott or he was the first to explain the exact nature of congenital hernia, which Haller indeed had described before either of them; and further, on account of his controversy as to whether Haller or he first ascertained the insensibility of the dura mater, of tendons, and of ligaments; and although each was in respect to these points an independent discoverer, it is quite certain Hunter corrected Haller when the latter concluded that these parts had absolutely *no sensation;* and finally, and sorrowfully be it said, William Hunter is remembered on account of his quarrel—bitter, prolonged, and notorious—with his brother, John Hunter, who is still more famous than himself, as to which of them first described the "structure of the placenta, the communication between it and the uterus, and the vascularity of the spongy chorion."

But though there are many reasons why William Hunter has found a permanent place in the history of medicine, the name of poor Thomas Brookhouse Cheshire would have passed completely into oblivion had he not been "bled in the arm by a person who was reputed a good bleeder though not of the profession," and had not an accident which occurred in the course of the operation been followed by "a particular species of aneurysm never before described."

It was on August 24th, 1761, that Dr. William Hunter read a paper[2] before "*a Society of Physicians in London*" on the sequelæ of this accident to Cheshire, and he gave therein such an accurate and complete account of them and of his own very careful observations and experiments on the case, that this paper at once became authoritative, and has served as the basis and pattern of every account of arterio-venous aneurysms which has ever since been written, no matter who the writer.

In another paper,[3] read a few years earlier at the same society of physicians, Dr. Hunter, in the course of some remarks on aneurysm in general, asked the question: "Does it ever happen in surgery, when an artery is opened through a vein, that a communication, or *anastomosis*, is afterwards kept up between these two vessels? It is easy to conceive this case; and it is not long since I was consulted about one which had all the symptoms which may be expected, supposing such a thing to have actually happened, and such symptoms as otherwise must be allowed to be very unaccountable." Here, we remark, is to be seen the influence of one of the great apostles of the deductive method of reasoning—the great Scotch pathologist Cullen—at work in the mind of his friend and former pupil, William Hunter; and here was a hypothesis which Hunter quickly converted into a positive fact by his practical and experimental manner of examining the ailments of the man Cheshire and another. The result of these examinations was such a perfect delineation of arterio-venous aneurysms that subsequent experienced and accomplished surgeons have not been able to improve upon it, though it is true that by means of it they have been enabled to show that arterio-venous communications are produced by disease as well as by injury, and occur between arteries and veins other than the particular vessels at the bend of the elbow, which exclusively were the subject of Hunter's investigations. The case, for instance, which I bring before you to-day differs widely from Hunter's cases as to the vessels involved; but instead of relating it in detail I will give you as far as possible in Hunter's very words his own narrative of the symptoms which is *cæteris paribus* equally applicable to every case of aneurysmal varix.

WILLIAM HUNTER'S ACCOUNT OF ARTERIO-VENOUS ANEURYSM.

Cheshire's condition when Hunter saw it had been much the same for five years, and the condition of the other patient had been stationary for twice as long. In each case the cause of the accident was venesection at the bend of the arm; in each a communication had been established between the brachial artery and the basilic vein. Cheshire told Hunter that "he felt at the time as if the lancet had gone too deep"; the bleeding which followed was easily stopped, and for the first two days he observed nothing uncommon except that his arm was black and blue down to his wrist. On the third day he noticed a swelling, almost as large as it was five years later, at the part where he was bled. He thought it had altered very little. His arm appeared to him to have as much life and strength as it ever had, and he used it as freely as the other, even in laborious employment. Being a thin man, the appearances in the arm were very distinct. There was a great difference in the brachial artery above and below the point of communication with the basilic vein. The trunk of the artery all the way down the arm was considerably enlarged and its pulsation was so strong as to be apparent to the sight, whereas the artery at the wrist was much smaller and its pulsation much weaker than in the natural limb. At the place where the wound had been "a bag rises up, projecting as much as if there was a large nutmeg under the skin. This bag is filled entirely with fluid blood, disappears under pressure, and has a strong pulsation. Its deepest part is manifestly united with the artery. Over the most prominent part of this bag the basilic vein runs, and is so firmly united to it, and blended with it by communication, that it is difficult to determine whether the bag be a sinuous dilatation of a part of the vein or if it be an adventitious cavity between the artery and vein formed in the cellular membrane, though I am more inclined to believe the last." Hunter minutely described how in one case the trunk of the vein may keep close to the trunk of the artery, and the margins of the orifices of the two vessels become soldered together, so that there is nothing like a canal between, and then the whole tumefaction will be more like varicose veins only; whilst in another case the cellular membrane between the two vessels may become widened out

[1] Lecture I. was published in THE LANCET of May 28th, 1910, p. 1455.
[2] Medical Observations and Inquiries, vol. ii., 1764.
[3] Medical Observations and Inquiries, vol. i., 1757.

into a little sac, as in a common traumatic aneurysm, and so a sort of canal may be formed between the two vessels on the under aspect of the vein along which the blood will pass from the artery into the orifice in the vein, and the trunk of the vein will be removed to a little distance from the trunk of the artery.

Here, we must note in passing, is proof that Hunter had in his mind a clear idea of the difference between the form of arterio-venous aneurysm which we now call aneurysmal varix and that which we now call varicose aneurysm.

Hunter went on to point out what he considered to be the evidence in favour of there being a communication of this bag with both the artery and vein. The basilic vein was greatly enlarged for a considerable way upwards from the point where the puncture was made in bleeding. When the arm hung down the distension of the vein was very apparent; when the arm was held up the vein subsided and no swelling whatever was seen except just at the punctured place, where the bag continued as much dilated as when the arm hung down. Besides pulsation there was a peculiar tremulous motion both in the bag and in the dilated vein as if the blood had been squirted into it through a small hole. Hunter compared this motion to what is produced in the mouth when the letter "r" is continued in a whisper. It was strongest at the point of puncture and became gradually less perceptible from there upwards. It was apparent to the sight. It was stopped by pressing the trunk of the artery anywhere above, or by pressing the bag or the vein at the punctured part, where the point of the finger was of sufficient breadth for that purpose. On the compression being discontinued the tremulous motion instantly returned, and that, too, whether the arm hung down or was held up; and whether it was free or girded by a ligature below the punctured part. When the ear was held near the part, and much more distinctly if the ear was touching the skin, there was heard "a hissing noise, as if there was a blast of air through a small hole, and interrupted, answering precisely and constantly to the stroke of the heart or diastole of the artery." It stopped immediately when the trunk of the artery was compressed and returned instantly when the artery was free. The noise kept the man awake if his arm was near his head, and he had to put the limb down by his side in order to go to rest. There was no coagulum present, for when the bag and vein were emptied by pressure on the arterial trunk above there was no more thickness or fulness about them than natural. On ceasing to compress the arterial trunk the emptied bag and vein immediately refilled. When a ligature was applied round the top of the forearm tight enough to stop the pulse at the wrist, the bag and the dilated vein and the tremulous noise in them continued as before the ligature was applied. If in this state the bag and the vein were emptied by pressure they did not remain empty but filled again instantly, and this experiment succeeded in the same manner when repeated any number of times. But while the ligature remained on the forearm, if the trunk of the brachial artery was compressed without touching the adjacent vein, the bag and swelled veins subsided and remained empty till the pressure on the artery ceased, and the tremulous motion also ceased. As the blood returned in the bag and vein on discontinuing the pressure on the artery, very close watching revealed the rushing of the blood down the artery, then across the bag, and then flying upward in the vein. The return of blood was so quick that unless the closest attention was given the three several parts seemed to be filled by one instantaneous jerk. With the ligature still tight on the forearm, if another ligature was tightly applied round the middle of the arm, taking care to have the dilated part of the vein pretty full of blood, on pressing the bag the blood returned into the artery and distended it; and when the pressure was taken from the bag the artery emptied itself and grew flaccid, so that by repeated and successive pressure the blood intercepted by the two ligatures was made to undulate sensibly from the artery to the bag, and *vice versâ*. "All these observations and experiments were made and repeated before the members of the society and other gentlemen of the profession; and," continued Hunter, "I am persuaded that nothing more is wanted to establish this new and useful observation in surgery but an opportunity of examining one such case after death."

In the first case which Dr. W. Hunter described, a surgeon in the country, when bleeding a young lady in the basilic vein, instantly realised that he had wounded the brachial artery by the violence and "*saltus*" of the stream that gushed from the vein. Varied and prolonged compression failed in preventing the formation of an aneurysm. This aneurysm acquired a considerable bulk, and when Hunter saw the patient for the first time—several years after the accident—he remarked when speaking of the limb: "The appearance was very particular, and so different from anything of the kind I had ever seen, that it engaged my attention and curiosity, and made me examine it with care, in a variety of different ways."

Here we find William Hunter obsessed by the same spirit which was ever at work so imperiously in his brother John Hunter. The spirit of the true inquirer. "Attention" and "curiosity"! It seemed to say, "Take note of everything you can see, feel, hear, smell, or taste; but do not let that suffice you! Try this way and that, one method after another method, and find out what more is discoverable, what more the senses can detect, beyond what is obvious to unassisted though careful observation only."

Hunter then goes on: "The veins at the bending of the arm, and especially the basilic,—the vein that had been opened,—were prodigiously enlarged at that place, and came gradually to their natural size, nearly at about two inches above, and as much below the elbow. When emptied by pressure, they filled again almost instantaneously; and this happened even when a ligature was applied tight round the forearm, immediately below the affected part. Both when the ligature was made tight and when it was removed, they" (the swollen veins) "shrunk and remained of a small size, while the finger was kept tight upon the artery, at the part where the vein had been opened in bleeding. There was a general swelling or fulness at the affected part and in the course of the artery, which seemed to be larger, and to beat stronger than what is natural, all the way down the arm. There was likewise a pulsation in the dilated veins, corresponding to the pulse of the artery; and there was a hissing sound and a tremulous jarring motion in the veins, which was very remarkable at the part that had been punctured, and became insensible at some distance both upwards and downwards."

The young lady having been told of Cheshire's condition wrote on Sept. 14th, 1761: "I am very sorry to hear I have a fellow sufferer in the case of my arm. The best comfort I can give the person you mention is, that it is now about 14 years since I met with the accident. I do not find that it [the arm] is much worse than when you saw it, though I think the veins that lie over the artery are rather more enlarged. But I have never attempted to do anything to it, nor do I find any uneasiness from it more than that I cannot sleep on that side without feeling such a sensation as if all my blood was centred in my arm. There is no congested blood in the wounded part, for when I hold my arm up to my head the blood entirely returns and the veins are as empty as they would be in my other arm."

Scarpa, referring to this patient, says, "In the lady who was the subject of the first of Dr. Hunter's observations, after 35 years the aneurysmal varix was nearly in the same state in which it was soon after the accident." Mr. B. Bell, with reference to Dr. Cleghorn's patient (to be again alluded to later on), stated that he had learnt that the varicose aneurysm after 20 years had not experienced any other change than a little more swelling of the veins in the bend of the arm communicating with the aneurysmal varix; and that, notwithstanding this he made use of his arm as before, and had resumed his trade of shoemaker.

In the operation of bleeding, if the artery is wounded by the lancet passing into it through the vein, there will be two wounds in the vein and one in the artery, and all will be quite or nearly opposite to each other and to the wound in the skin. The wound in the skin and in the adjacent upper side of the vein heal up as usual, but the wound in the artery and in the adjacent underside of the vein remain open, and by that means the blood is thrown from the trunk of the artery directly into the trunk of the vein. The communication in different cases, as Hunter pointed out, will be found to differ in many little circumstances; thus the venous dilatation may affect only one vein or several, and may extend from the seat of puncture further upwards or downwards in one case than in another, according to the manner of branching, the state of the valves of the veins, the size of the artery wounded, and the size of the orifices in the artery and vein. The shape and size of the sac in varicose aneurysms will vary

in different cases according to the degree of resistance of the cellular tissue, and owing to its being unequally bound down by the bicipital fascia; and if the sac be very large or irregular some coagulation of blood might take place in it as in a common false aneurysm.

Arterio-venous aneurysm differs from an ordinary false aneurysm following punctured wound, in one circumstance only—namely, the persistent communication between artery and vein. But this one circumstance occasions a great deal of difference in symptoms, prognosis, and treatment.

I. In its symptoms the arterio-venous differs from the common false aneurysm in the following particulars: the vein is dilated, varicose, pulsative, and the seat of a jarring motion and a buzzing noise; the blood of the tumour is altogether or almost entirely fluid, because it is kept in constant movement; the artery becomes larger on the cardiac side and smaller on the distal side of the tumour than in the normal state; whilst the effects of ligatures around the limb and of direct pressure on the vessels have been described above.

II. The natural tendency of a false aneurysm is to grow worse and worse and ultimately to become diffused, whereas the arterio-venous aneurysm soon attains a permanent state, and if not disturbed produces no further mischief, because there is no considerable resistance to the blood that is forced out of the artery. Hunter's and Cleghorn's cases confirm this.

III. The proper treatment in the two cases is very different, "the spurious aneurysm requiring chirurgical assistance as much perhaps as any disease whatever, whereas in the other case I presume it will be best to do nothing." Hunter never seemed to have any doubt as to the wisdom of leaving matters alone. He seems instinctively to have arrived at this conclusion. Although the first case he described had been sent to him as one in which the aneurysm had acquired such a considerable bulk that it would soon burst if she did not submit to "*the operation*,"[4] Hunter decided against interfering. He remarked: "Though such a case had never before entered into my thoughts I was so well convinced, by the symptoms, of its arising from a communication between the artery and vein, that I gave an opinion to that purpose, and therefore advised her to do nothing while there should be no considerable alteration." Yet he was dealing with an affection which, as he said, "was entirely new to myself and appeared incredible or incomprehensible to some others."

I do not know in the whole history of medicine of any other instance in which either a medical or surgical disease has been so correctly, so clearly, so completely, and yet so cautiously made out by, as it were, a single stroke, and with reference equally as to its cause, symptoms, diagnosis, pathological changes, prognosis, and treatment, as was arterio-venous aneurysm by Dr. Wm. Hunter. For this reason, and because of the inaccessibility of the volumes which contain the papers referred to, I have taken this opportunity of bringing Hunter's own statements and views to your notice.

Cheshire's case and Hunter's narrative of it will always interest Middlesex Hospital men, and it affords a brilliant example of the value, when investigating disease, of combining hypothesis with observation and experiment, and of reasoning from the facts elicited by the two latter processes to test the accuracy or otherwise of the first.

It is astonishing that this affection continued to go unrecognised until the latter part of the eighteenth century, and that no one before Hunter should have discovered it; and it is all the more astonishing if we consider the hundreds, possibly thousands, of instances of it, to which the accidents attending venesection during many centuries had probably given rise.

RESULTS OF PUNCTURED WOUND OF ARTERY THROUGH A VEIN.

There are, it is true, a variety of consequences which may follow a punctured wound of an artery through a vein. Their occurrence depends on whether both sides, or only one side, of the artery as well as both sides of the vein are penetrated, and whether one or other, or all the wounds heal, and heal permanently, as the result of the compression employed for controlling the immediate hæmorrhage. In Rudolph Matas' article in Keen's "Surgery" there are eight varieties illustrated (coloured diagrams of them were exhibited at the lecture), but several of them must be of most exceptionable occurrence. There is, however, strong presumptive evidence that arterio-venous aneurysms were met with throughout the previous centuries but were not recognised as a special form distinct from the common false aneurysms. Thus Sennertus (1572–1637), writing in the earlier part of the seventeenth century, in his chapter on aneurysms, speaks of a lady who for 30 years had an aneurysm on the inner side of the front of the elbow, the size of a walnut, which followed venesection, and in which there was a tremor felt and a hissing noise heard when the ear was applied close, like that of blowing air through a narrow opening; and he adds that so far she had remained quite comfortable, and therefore that it is often better to put up with this state of things rather than subject oneself to a risky cure. It will be noted that the description given by Sennertus is in much the same words as those employed by William Hunter. There is also corroborative proof of this opinion afforded as Dr. Cleghorn suggested, in the "noise which Paulus and others perceived on touching aneurysms," which Paré expresses by the word "*fisslement*," and Municks compared to the "*strepitus bullientis aquæ*." I am, however, disposed to think that the common form of aneurysm which had formerly been seen after venesection accidents was the simple false aneurysm. The numerous dissections, after amputation or death, described in Scarpa's book and elsewhere, of aneurysms at the bend of the elbow, are of this variety.

The great attention which the old surgeons paid to methodical compression after venesection when a wound of the brachial artery was thought to have been inflicted, is shown by the precise description which Galen gave of his own use of a sponge; which Genga[5] (1673) gave of the bandage known by his name and by that of Theden also; by Desault's employment of his "semi-canal" splint; and by the celebrated Brambilla's (1728–1800) advocacy of chewed paper and graduated compresses "as the surest of all compresses for immediately healing a wounded artery and preventing aneurysm." These measures no doubt were effective in many cases in bringing about the immediate reunion of the wounded artery, and in thus preventing the generation of aneurysmal varix; but whilst the incisions in the vein, like that in the skin, remained permanently healed, that in the artery subsequently yielded and a false aneurysm resulted, just as we see happens after the healing of a simple puncture of an artery. Indeed, in 1763, within two years after Hunter read his second paper, one of the ablest anatomists and most celebrated professors in Europe pretended to demonstrate to a numerous audience that a persistent communication between an artery and a vein could never happen (Cleghorn).

CASES RECORDED BY OTHER OBSERVERS.

Of course, Hunter's title to being the first to describe arterio-venous aneurysms did not long remain unchallenged. Dr. George Cleghorn[6] (1716–1789), lecturer on anatomy in Dublin, and an exact contemporary of William Hunter, was the first to suggest the term "aneurysmal varix." This he did when reporting a case of the sort in April, 1765, and at the same time he took the opportunity of declaring that in his opinion Hunter had made "one of the most ingenious and happy discoveries which modern times had added" to surgical science. Benjamin Bell (1749–1806), also a contemporary, though a much younger man than Hunter, originated the name "varicose aneurysm," but he also fully and freely acknowledged Hunter's priority in describing the characteristic features of arterio-venous aneurysm. Scarpa (1752–1832), too, who was of the same date as Benjamin Bell, did likewise, but he also made a similar claim for his countryman Guattani, who, he said, described the true nature of this particular kind of aneurysm and published the history of two cases of the sort before ever Hunter's investigations were known in Italy, and that Guattani, therefore, deserved "an equal share in the merit of the discovery." But Guattani did not see his first case until 1769, and his book was not published till 1772, whereas William Hunter's papers were published in 1757 and 1764.

[4] By "*the operation*" is meant Anel's, or else the radical operation of laying open the aneurysm. Anel died in 1730; and when Hunter was writing, Anel's operation had long been in use. J. Hunter's operation for popliteal aneurysm had not yet been introduced. William Hunter died in 1783 and it was not until two years later—viz., in 1785—that John Hunter performed his first ("the Hunterian") operation.

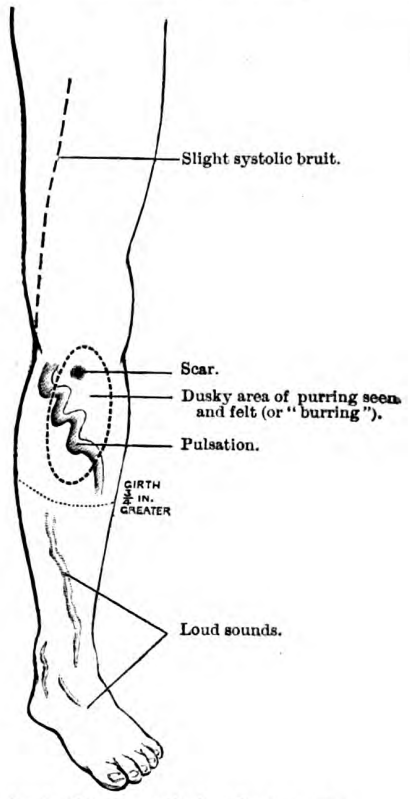
[5] Scarpa on Aneurysm, second edition, 1819.

[6] Medical Observations and Inquiries, vol. iii., 1767.

John Bell (1763–1820) and Charles Bell (1774–1842) equally followed Hunter's observations when writing their own descriptions; though whether they sufficiently acknowledged the source of their information or not is another matter.

Hunter had said: "I am persuaded that nothing more is wanted to establish this new and useful observation in surgery but an opportunity of examining one such case after death." Such proof was supplied by Mr. Park[7] of Liverpool (1745–1831), not, indeed, on the dead subject, but on the arm of a living patient in the course of performing a radical cure in 1791. A beautiful illustration of this case of "varicose aneurysm" is given in John Bell's "The Principles of Surgery."[8]

W. Hunter's note of the noise in the veins being like "a blast of air sent through a small hole" recalls the description by Sennertus above referred to, and the simile has been used by Charles Bell and others. But this sound has been compared with many others—for example, with the noise of a bee in a paper bag, with the whirr and buzz of machinery, the purring of a cat, droning of bees, and the humming of a top. In a case involving the femoral vessels which we had in this hospital many years ago Mr. Hulke described the noise as "not unlike the roar of a large bellows and positively painful to listen to."[9] Dr. Cleghorn, writing to Dr. Hunter in 1765, said of his own case, which he had exhibited to his class and to a number of medical men, "Some gentlemen compared it to the noise of a whirlwind; others to that of a nut-mill; others to that of a woollen spinning-wheel; others to the waves of the sea; others to a boiling tea-kettle. The patient himself says that when he leans his head on the affected arm he hears a noise like the buzzing of bees, and the peasants acquainted with this young man's indisposition, assured him he had got a bee in his arm."



OCCURRENCE OF ARTERIO-VENOUS ANEURYSM IN VARIOUS PARTS OF THE BODY.

Hunter described arterio-venous aneurysms at the bend of the elbow only, and Charles Bell, writing in 1807, stated that aneurysmal varix "happens only after bleeding in the median basilic vein." Subsequent experience, however, has shown that aneurysmal varix (not varicose aneurysm) may be established by disease as well as by injury, in many parts of the body. Such direct communication between artery and vein, the result of ulceration, has been recorded between the aorta and vena cava, and between the iliac, femoral, carotid, and subclavian arteries and their companion veins. Varicose aneurysms never occur from disease. In some instances aneurysmal varix is congenital, as in a case described in Bryant's "Surgery," in which the communication was in the axilla.

As the result of injury Baron Larrey (1766–1842) tells of a case under his uncle, who was a surgeon at Toulouse, of aneurysmal varix occasioned by a sword wound of the popliteal artery and vein. He himself had a case of aneurysmal varix situated under the clavicle, the result of a sabre wound in a duel; and a second case of aneurysmal varix, involving all the veins of the arm, caused by a sword wound of the axilla.

Dr. Orsey of Philadelphia in 1813 published a case of varicose aneurysm due to a wound in the leg with buck shot. Dissection after death showed a communication between the posterior tibial artery and vein through an intermediate sac situated on the inside of the leg just below the knee. Mr. Joseph Hodgson (1788–1869) recorded[10] cases of aneurysmal varix of the lower limb; in one case the femoral artery and vein, four inches below Poupart's ligament, were wounded by the point of a heated iron rod; in the other a communication between the popliteal artery and vein was the consequence of a wound with a pistol ball. Agnew[11] saw a case in which after separation of a ligature which had included both femoral artery and vein, the channels of these vessels communicated.

In 1875 I had the opportunity of studying a case of aneurysmal varix of the femoral vessels caused by the accidental discharge of a pistol, and of witnessing the absolute failure of digital and instrumental pressure. On Oct. 29th, 1909, I saw the case of which the accompanying woodcut gives some idea. The patient was a girl, aged 7, who had accidentally punctured with scissors the upper part of the front of the leg. There was very little bleeding at the time. Some months afterwards the family medical attendant, observing that the veins of the leg and foot had become prominent, arranged for an operation for varicose veins by Mr. Carwardine of Bristol, to whom the patient was sent for the purpose on Oct. 6th, 1909. When he saw the condition, Mr. Carwardine naturally declined to undertake the operation, and sent her to see me. There were all the signs of an aneurysmal varix. The dilated or varicose superficial veins are well shown in the figure; the purring noise in the long saphena was very faint above the knee, compared with it in the lower part of the leg and at the ankle; the purring vibration

Aneurysmal varix of leg in a patient aged seven years.

and murmur and the pulsation were all best marked within the area indicated by the dotted outline in the figure. The vessels involved are, I believe, either the upper parts of the anterior tibial themselves, or primary branches of those vessels. The case seems worth recording as it must be very rare for a communication to be made between vein and artery in this situation. There is nothing peculiar in the case, however, on account of the youth of the patient, because, given the requisite conditions, an arterio-venous aneurysm may occur at any age.

Arterio-venous aneurysms as a rule require no treatment beyond the avoidance of direct injury or strain, and some restraint as to the amount and variety of exercise of the limb. It is now universally recognised that aneurysmal varix should be left uninterfered with. The use of the ligature has been much more frequently followed by a fatal result in this form of aneurysm than in the spontaneous forms of the disease, and the employment of pressure in any manner whatever has been far less successful. An elastic stocking has been found to be of the greatest value in aneurysmal varix of the lower limb. In varicose aneurysm an operation is only to be thought of when the disease is causing marked functional disability, or is interfering with the nutrition and usefulness of the limb. Then a ligature should be applied immediately above, and another immediately below the sac, and in the event of an anastomosing branch

coming off between these two ligatures a third ligature should be placed around the communicating aperture of the artery (Agnew). The vein should be left untouched. It is only in cases in which the aneurysm becomes diffused that laying open the sac and ligaturing the artery above and below the aperture in it has been thought necessary.

[The various modern methods (endo-aneurysmorrhaphy) for closing the openings in vessels were described, but it was pointed out that their application in arterio-venous aneurysms can hardly ever be justifiable in actual practice.]

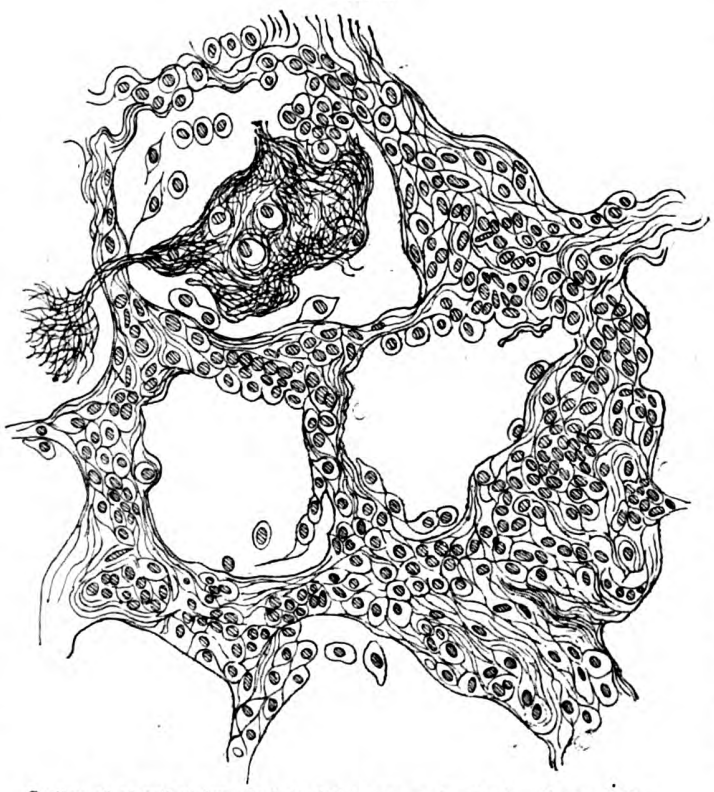
A Lecture
ON
THE RELATION OF FIBROSIS TO TUBERCULOSIS.

Delivered at the Hospital for Consumption and Diseases of the Chest, Brompton, on March 9th, 1910,

BY C. THEODORE WILLIAMS, M.V.O., M.D., F.R.C.P.,
CONSULTING PHYSICIAN TO THE HOSPITAL.

GENTLEMEN,—In the present lecture I propose to discuss fibrosis in relation to the changes in the lungs, which the ravages of the tubercle bacillus cause in the structure and functions of those organs, and I hope to prove to you that as the bacillus is the destructive element in the tubercular process, so fibrosis is the protecting element, by which Nature resists the advances and limits the inroads of the microbe in the lungs and other organs. It is not improbable that the process of fibrosis is Nature's answer to the bacillar attack, and that it is evolved by the tissues from the stimulating effect of the poison on them.

VARIETIES OF FIBROSIS OF THE LUNGS.



There are at least three different kinds of fibrosis varying in origin, growth, and vitality. The first is the growth accompanying, or following, pleurisy, and generally has its origin in the pleura, which becomes adherent and considerably thickened. Here the fibroid growth consists principally of interlobular tissue, and being largely increased compresses the adjoining lung tissue. Interlobular fibrous growth is much coarser and tougher than the fibrosis originating in tubercle, and being abundantly supplied with blood-vessels becomes organised and long lived, especially as the arteries which are derived from the bronchial system are not liable to be obstructed and obliterated. This tissue is distinguished by its white colour and its relation to the lobes and pleura, embracing the former and starting as invading processes from the latter. It is the cause of large tracts of lung tissue being obliterated, not only the tubercular portions, but sometimes in chronic pleurisy tracts of healthy lung tissue may become involved and compressed under its contracting influence. When this is so the patient becomes habitually short-breathed. Interlobular fibroid growth with thickened pleura invariably causes flattening of the thorax and contraction of the affected chest.

A second form of fibrosis originates in interstitial pneumonia,[1] which prevails among those who pursue dusty occupations and inhale fine particles of iron, grit, coal, and stone, such as knife and fork grinders, stonemasons, potters, and colliers. The inhalation of these particles induces first bronchial and alveolar catarrh, and then inflammatory exudation of fibrin and leucocytes into the alveoli and a thickening of the alveolar wall by a cellular infiltration, from which the cells gradually disappear, leaving a more or less fibrous structure. What is generally noted in these cases is that the new product fills the alveoli completely and infiltrates the walls. The fibrous plugs in the alveoli produced by the exudation may be seen attached to the walls of the alveolus by two or three processes each containing a small vessel.[2] (Fig. 1.)

Tiny capillaries are to be seen occasionally perforating the walls so that the plugs of neighbouring alveoli are joined together in one vascular network. In addition there is a distinct thickening of the alveolar wall from cellular proliferation.

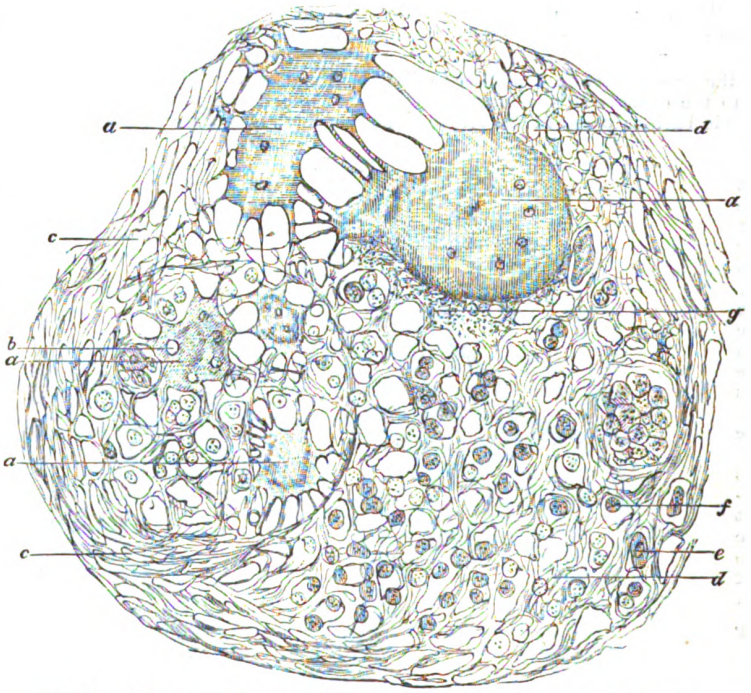
Interstitial pneumonia, sometimes called chronic pneumonia, may arise in others than workers in dusty occupations, and is often the result of catarrh or pneumonia, but its characteristic feature is the infiltration of the lung structure by fibrosis, which in time obliterates the alveoli and converts the whole organ into a slaty-grey fibroid mass impermeable to air. The middle and lower lobes of the lungs are more frequently the seat of this affection than the upper. Both these classes of fibroid tissue are well organised and tough, and being well supplied with blood-vessels show great vitality. Their characteristic features are: (1) their tendency to contraction, for a lung infiltrated with fibrosis will shrink in volume to one-half or one-third of its size; and (2) the dilatation of the bronchi, which is generally present.

FIG. 1.

Section of alveoli of lung in interstitial pneumonia, showing the exudation undergoing organisation through vascular extension, with thickening of the alveolar wall by cellular proliferation.

The third form of fibrosis is that which supervenes on tubercle, and indeed may be termed its product, for the late Dr. Moxon was not far wrong when he described fibrosis (this form of) as the past tense of tubercle.

[1] This variety is probably the same as Addison's "grey induration," of which good examples will be found reported by Dr. Sidney Coupland (Pathological Transactions, vol. xxx., p. 224) and by Dr. Percy Kidd (Medical Society's Transactions, vol. xiii., p. 328).



[2] For the illustration I am indebted to "Fibroid Diseases of the Lungs" by Sir A. Clark and Dr. Hadley and Dr. Chaplin, whose publishers, Messrs. Charles Griffin and Company, Limited, have kindly permitted me to use the block.

PATHOLOGICAL FEATURES.

The supervention of fibrosis in a case of pulmonary tuberculosis is characterised by well-marked pathological features and by certain clinical symptoms, but perhaps it would be well to consider the former first. We find after death in cases of old disease that the conversion of tubercle into fibrosis is a gradual process, which was ably described by the late Professor Hamilton of Aberdeen,[3] from whose work Fig. 2 has been taken.[4]

When a miliary tubercle is first formed it is seen under the microscope to be mainly cellular, but it soon undergoes changes in two directions: first, the epithelial cells undergo caseous change, and are transformed into the yellow tubercle of Laennec; and secondly, some of the cells, chiefly those of epithelial origin, become converted into giant cells, which have branched processes extending in various directions. These unite with the branched processes of the adjoining giant cells and form a fine network which is gradually converted into fibroid tissue, the nuclei and nucleoli disappearing, and nothing remaining but fibres. This tissue, once formed, spreads. The effect of this growth on a tubercular lung is very remarkable. Masses of comparatively freshly formed tubercle undergo fibrotic changes or become enveloped in the fibrous strands and, being deprived of blood-supply, degenerate into caseous material. This effect is best seen in the neighbourhood of cavities undergoing contraction, of which some striking examples are exhibited.

FIG. 2.

Fully developed tubercle of lung × 450 diameters. *a*, *a*, *a*, Giant cells. *b*, Vacuole in one of these. *c*, Peripheral capsule of fibrous tissue. *d*, Reticulum of the tubercle. *e*, Large endothelial-like cells lying on the reticulum and within its meshes. *f*, Smaller lymphoid cells occupying the same situations. *g*, Peripheral fibrous-looking periplast of the giant cell. In the upper portion of the drawing two giant cells are seen joining their branched processes, and further to the right the resulting network and fibrous striæ can be distinguished.

Two marked features of this form of fibrosis are that the lung becomes deeply pigmented and that it shrinks in size considerably. In certain cases of long standing, after death the affected lung is found contracted to the size of a man's fist and lying at the bottom of the thoracic cavity close to the spine. When laid open the lung presents a tough, slaty-grey fibrous structure, impervious to air, and with the remains of an old cavity with blocked bronchus. The opposite lung, when healthy, or if only slightly diseased, is enormously hypertrophied, and is found stretching across the median line and occupying, in addition to its own side, that portion of the opposite side from which the diseased lung has retreated.

The method by which contraction of cavities is brought about is remarkable. The fibroid tissue into which the tubercle has been transformed commences to contract; the cavity wall becomes wrinkled; the bronchus leading to it, blocked either through lateral pressure or by plugs of accumulated mucus, and the contents of the cavity dry up or become cretaceous. Cavities shrink to one-half or one-third of their size, leaving a narrow channel of irregular form, but they seldom entirely close, and absolute cicatrisation of a cavity is very rare. Now when you examine any of these chronic tubercular lungs you will find traces of several pathological processes. First, considerable thickening of the pleura. Secondly, great increase of the interlobular tissue, the white strands of which pass from pleura to root of lung and squeeze the lung, diseased or healthy, between them. This tissue is very tough and shining. Thirdly, we find the grey and black fibroid tissue of transformed tubercle encircling old caseous masses and old cavities and cutting off all blood-supply. Then we come to cavities as yet uncontracted, whose walls are still secreting, and lower down towards the pulmonary bases we find more recent tubercular masses, and even miliary tubercle, scattered throughout the healthy lung tissue.

CLINICAL FEATURES.

Having discussed the pathology of fibrosis, it behoves us to say a few words on the clinical features of patients in whom fibrosis is taking place, as the symptoms are often very striking. In the first and second varieties of fibrosis, where tubercle is not necessarily present, the principal symptoms are: shortness of breath, most marked on ascents, and sometimes pain in the affected side, cough with probably scant expectoration or none at all, loss of flesh and often of colour. If the breath be very short there are usually signs of obstructed circulation and a dilated heart, with œdema of the lower extremities. The chief external feature is the flattening of the chest wall and the contraction of the affected side, which is present in all these cases. The second variety of fibrosis is practically that described by Corrigan as cirrhosis of the lung and by Sir Andrew Clark[5] erroneously as fibroid phthisis, for tubercle is not necessarily an element of this class, though it may supervene occasionally in cases. The symptoms have been well described by both these authors.

The physical signs of these two varieties indicate shrinking of the one lung and the extension of the opposite lung to fill the void caused by the retraction of the diseased one. Displacement of organs is noted as regards the heart, liver, and stomach. The heart is drawn towards the contracted lung, and the liver and stomach raised alternately according as the right or left lung is affected.

The symptoms in cases of the third variety of fibrosis—viz., that following tubercle—are characteristic. The supervention of tubercle by fibrosis is marked by decided improvement in all the patient's symptoms except his breath; cough and expectoration diminish. Tubercle bacilli disappear from the sputum, all pyrexia and night sweats disappear, large gain of weight takes place (often as much as a stone), the chest wall becomes flattened and contracted, the circumference of the affected side becomes smaller than the

[3] The Pathology of Bronchitis, p. 170 et seq.

[4] I am indebted to Messrs. Macmillan, the publishers of Professor Hamilton's book, for the use of this block.

[5] Fibroid Diseases of the Lung, including Fibroid Phthisis (Clark, Hadley, and Chaplin, 1894).

healthy one by one or more inches, and the respiratory movement is much less marked. But the breath is decidedly shorter, and the dyspnœa always increases on exertion. This is so marked a symptom that one can almost diagnose the extent of fibrosis by the amount of dyspnœa present.

When the upper lobe of the right lung is the seat of a contracting cavity it is not rare for the middle and lower lobes to be drawn up and rendered emphysematous by traction, and this will sometimes suffice to fill in the void left by the contracting lung, and then there will be no further displacement of organs. When there is extensive pleuritic adhesion the process of contraction is very persistent and the thoracic wall very rigid and unyielding; either the pleura becomes thickened or appears to develop meshes into which fluid is effused, or else fat forms between the ribs and the parietal pleura. A very important displacement is that of the opposite lung, which becomes hypertrophied and increases to nearly double its normal size, and it can be detected by physical signs under the sternum halfway across the opposite chest wall. Contracting cavities contract towards fixed points, generally towards the root of the lung, or where strong pleuritic adhesions exist they may contract towards these and give rise to displacement of other organs beside the neighbouring lung, according to the relative position of the cavity and adjoining organ.

Where the contracting cavity is in the right lung the liver is drawn up and the upper edge of this organ may be raised as high as the fourth rib. The left lung and heart may be drawn across the median line and the pulsation of the latter may be visible in the second and third interspaces, and the apex has been detected near the right nipple, but this is rare, and generally the heart's position is beneath the sternum and slightly to the right of it.

When the cavity is in the left lung the displacement of organs is far more marked. The right lung may be drawn considerably over to the left side; the stomach may mount up to the fifth rib; and the heart may be uncovered and drawn upwards through retraction of the left lung, and then comes into contact with a considerable surface of the chest wall, and its action is visible in the first and second costal spaces. In this change of the heart's position the course of the apex seems to be upwards, outwards, and towards the axilla, often describing the arc of a circle, of which some point in the neighbourhood of the aortic valves is the centre. First the apex is felt in the fourth interspace, then in the third interspace rather to the outside of the nipple, and at last it is found in the axilla. There is sometimes a twisting of the heart on itself, causing a slight obstruction in the aorta, which occasionally gives rise to a systolic murmur, but leaves no lesion after death.

Flattening of the chest wall over the affected lung has already been alluded to, and over large cavities it is very conspicuous, combined with deficiency of motion of the side. In one case under my care the contraction gave rise to curvature of the spine. The cavity had been sufficiently extensive to produce tinkling sounds on cough. Changes take place in the cavities and the bronchi leading to them, the trabeculæ of the former being made up largely of the fibroid element, contract, and the infiltration of the walls of the bronchi cause them to shorten in length and to draw the cavity nearer to the root of the lung. This last causes a change of the region where cavernous sounds are audible, or as I call it, a "vagrancy" of the cavernous sounds. When the fibrosed lung has contracted towards its root the cavernous sounds formerly heard over the upper front chest are heard above the scapula and then in the interscapular region, and in time disappear altogether.

Fibrosis need not necessarily be a slow process, though it is usually so. I have known cavities in some patients to contract in a month and all signs of them disappear, while in other patients the same result is only attained in several years. In conclusion, I will give you a case of fibrosis where the process was extreme in its development and results.

A married woman, aged 29 years, a dressmaker, was admitted into the Brompton Hospital under my care on April 18th, 1871, with the following history. She had had a cough and expectoration for three years, and had noticed for two years that she was emaciating. Hæmoptysis to the extent of 4 ounces came on soon after the beginning of her illness; it was repeated to the same amount three months later, and again in February, 1869, another 2 ounces were coughed up. She had night sweats which ceased before admission, and once for two weeks she suffered from diarrhœa. Lately she had complained of increasing shortness of breath, which had become very troublesome. In September, 1869, she became an out-patient under Sir Richard Douglas Powell, who found flattening, dulness, and cavernous breathing in the upper right chest anteriorly, and tubular respiration and moist crepitation over the right posterior base. He observed that the left lung was enlarged and extended to the right of the sternum, and he detected crepitation at the apex, posteriorly. Sir R. Douglas Powell's diagnosis was—a cavity in, and contractile disease of, the right lung and granulations in the left lung. In October, 1869, she was admitted into the Brompton Hospital under the late Dr. Cotton, when the right lung was found to be in the same condition, but in the left, harsh blowing respiration had taken the place of the humid crepitus. She remained in the hospital for three months and under treatment gained 7½ pounds in weight, the physical signs remaining the same. After leaving the hospital she continued better for some time, but increasing dyspnœa caused her to apply for readmission, and she was readmitted under my care in April, 1871. Her cough was troublesome, expectoration was frothy, the tongue was clean, and the bowels were regular; the catamenia had been absent for two years; the countenance was pallid and the thorax was emaciated. The right side of the chest was considerably smaller than the left, the shoulder was depressed, and the upper part of the chest was fixed. Marked depression was visible in the upper right front as far as the third rib, this space being decidedly resonant. Cavernous sounds were heard under the clavicle, though chiefly below the sternal end. From the fifth rib downwards there was absence of breathing and marked dulness, not modified by change of position. Posteriorly cavernous breathing was audible in the right inter- and supra-scapular regions. The heart's sounds were more audible over the lower portion of the sternum than in the cardiac regions, and the apex could not be felt. It was therefore concluded that the heart was displaced towards the contracted side.

The diagnosis was "fibroid disease of the right lung with some excavation of the upper portion, and displacement of the left lung, liver, and heart towards the affected side." The patient was placed under treatment but did not improve, and on April 27th the evening temperature rose from normal to 100° F. 23 days later the morning temperature rose to 101° and the record remained between 100° and 101·6°, with the exception of one day, until May 4th. The patient became weaker and the breath shorter. Sonorous rhonchi and harsh breathing were audible in the left lung. On May 15th the morning temperature fell to 98·4°, the evening to 99°, the pulse being 100 and the respirations 40. After this the morning and evening temperature varied between 98° and 98·5°, and on May 20th the breath became very difficult. Crepitation was audible at the base of the left lung. The patient died from dyspnœa on May 25th.

The post-mortem examination was made by Mr. William Rose in the presence of Sir R. Douglas Powell and myself, of which the following is the record. The body was greatly emaciated; there was marked concavity from the right clavicle to the second rib and general shrinking of the whole right side of the chest. On removing the cartilages the right lung could not be distinguished at first, but was afterwards found contracted to a third of its normal size, occupying the axillary and lateral regions and not extending lower than the fifth rib. The heart was drawn over to the right side of the sternum, the apex lying slightly to the left of the ensiform cartilage. The liver, which was much enlarged, was drawn up, and owing to the retraction of the right lung had become superficial below the fifth rib. The left lung stretched across the median line as far as the right costo-sternal articulation, this being the case as low as the third rib. The right lung, weighing 20 ounces, was generally adherent to the chest wall, the pleura, with the intervening adhesions, being on an average half an inch thick and most dense over the diaphragm, where it contained in its interior a great deal of fibro-gelatinous material. The texture of the lung itself was dark grey, traversed by whitish fibrous bands proceeding from the pleura, interlobular septa, bronchi, and vascular sheaths. In the upper lobe were the remains of an old cavity into which some bronchi opened, their mucous membrane seeming to terminate at its entrance. The cavity appeared to have undergone

contraction and was divided by numerous fibrous septa stretching across it, separating it into smooth-walled loculi, which communicated with each other. The left lung was much enlarged and congested, the edges being highly emphysematous. It contained cheesy nodules, around which were miliary tubercles of recent date. In the portion drawn over to the right side was a cavity of the size of a walnut, which corresponded to the area of the cavernous respiration heard under the right clavicle. The heart was large, the right ventricle was slightly dilated, and the valves were healthy; the liver and spleen were both lardaceous; the kidneys were healthy.

In this case the shrinking of the right lung had caused remarkable changes. The chest wall was contracted, the liver pressed upwards, the heart was displaced to the right of the sternum, and the upper part of the left lung into the right chest. Owing to the portion of the left lung, which had been drawn over, containing a cavity, it gave rise to cavernous sounds under the right clavicle, from which it was naturally concluded that the cavity existed in the *right* lung, whereas, strange to say, it was in the *left* lung but in the right chest. It is probable that Sir R. Douglas Powell and Dr. Cotton listened to a different cavity from the one I detected, as their examination of the patient's chest was one and a half years before mine, and great changes intervened in that period, the right lung contracting steadily. Death was caused probably by the eruption of miliary tubercle in the left lung, by which the already limited respiratory area was still further reduced.

In conclusion, Gentlemen, the above facts show that though fibrosis is the process by which Nature resists the advance of tuberculosis, and limits its inroads, its progress and spread in the tissues are by no means an unmixed blessing to the patient, as it often obstructs the circulation, causing dropsy, and goes nigh to strangle him by reducing still further his already limited breathing surface.

SOME FURTHER INVESTIGATIONS AND OBSERVATIONS UPON THE PATHOLOGY OF RHEUMATIC FEVER.

BY F. J. POYNTON, M.D. LOND., F.R.C.P. LOND.,

HONORARY PHYSICIAN TO ST. SAVIOUR'S HOSPITAL, LONDON; ASSISTANT PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, AND TO UNIVERSITY COLLEGE HOSPITAL;

AND

ALEXANDER PAINE, M.D. LOND.,

DIRECTOR OF THE CANCER RESEARCH AND PATHOLOGICAL DEPARTMENT OF THE CANCER HOSPITAL, BROMPTON, S.W.; LECTURER ON BACTERIOLOGY AT THE BEDFORD COLLEGE FOR WOMEN, LONDON.

(From the Research Department of University College Hospital Medical School.)

IT is now close upon ten years since we published in THE LANCET[1] the first evidence that we had at our disposal upon the pathology of acute rheumatism, and while bringing forward some additional points we would shortly review the position as it seems to us to stand to-day.

In our first paper we attempted to show the relation of our own investigations to those of others, and with this we need not deal again here; in our later papers we also referred to the researches of other workers upon this subject, notably Dr. E. W. Ainley Walker,[2] Dr. W. Vernon Shaw,[3] and Professor J. M. Beattie.[4] Much interesting criticism has been directed against the two main conclusions we have so often stated, and which we venture to repeat here: first, that a diplococcus, streptococcus, or micrococcus is a cause and most probably the only exciting cause of acute rheumatism; secondly, that acute rheumatism may be a cause of simple and malignant endocarditis. We will at once clear the ground by adding that we are as convinced now as we were before that both these conclusions hold good. Some of the criticisms that have been put forward have been already answered, and in this paper we shall attempt to deal further with one of the most recent of them.

It has been suggested that we have been describing an agonal or terminal infection, but we have brought forward conclusive evidence to show that some of the patients from whom the micrococcus was isolated lived for many weeks afterwards, and that others were alive and at work some years later. This criticism may then be dismissed once and for all. Again, it has been suggested that the micrococcus may be present in complicated rheumatism as an epiphenomenon, as a cause, that is, of the complications. Having produced experimentally the important lesions of the disease,[5] we naturally ask in return what is to constitute acute rheumatism when deprived of arthritis, carditis, nodules, choreiform movements, and pleurisy? We hold that there is, as in tuberculosis, only a predisposition left in the sense that there is some vulnerability of the tissues to this infection, and that there is no mysterious disease "rheumatism," which is always associated with secondary infections. The idea that rheumatism produces arthritis, but that a secondary infection produces the endocarditis which is so often associated, may now be looked upon as contrary to all accurate knowledge. Another difficulty has been raised that this micrococcus is not constantly present and that we have even ourselves not always succeeded in isolating it. This is naturally a troublesome question to answer, and it has been made all the more so because this further criticism has been added, that when, on the one hand, some observers are repeatedly finding this micrococcus, and others of equal reputation are always failing, the success of those who obtain positive results is somewhat suspicious.

If, then, we fail to find the infective agent we must be convicted out of our own mouths, and if we find it we are suspects because others do not succeed. With regard to this micro-organism, all our own investigations go to prove that it is very constant. We have not demonstrated it in every case of acute rheumatism, but that is no proof that it may not be present, and, on the other hand, we have succeeded so repeatedly that we believe that we are in the position to say that if in any case one had unlimited scope and time for investigations the results would be quite constant. It is abundantly clear that we must choose the cases with care, and with a knowledge of pathological processes, selecting those in which the disease is active. It is a hopeless undertaking to investigate a case of chronic rheumatic heart disease which has been *in extremis* from secondary cardiac failure of mechanical origin, the result of the scars of former disease. Again, from one's knowledge of rheumatism, it is hardly likely that 10 cubic centimetres of blood taken at random from the general circulation is going to yield a positive result in a mild rheumatic arthritis.

The particular points that we wish to lay stress on now with reference to the isolation of this micrococcus are that we have upon several occasions demonstrated it in fatal rheumatism and that it has been simultaneously found by others in the same case; secondly, that we have worked with it when isolated not by ourselves but by others; and lastly, that we have isolated it from pericardial fluids obtained from fatal pericarditis by others who have forwarded to us the fluids in sealed tubes. These tubes we have incubated without opening, and as was the case in the first result we ever reported, the diplococcus was found in these fluids after incubation—that is, growing in the natural medium.

Example No. 1.—A girl, aged 7 years, was admitted to University College Hospital on March 25th, 1906, with a three weeks' history of acute malaise, vomiting, and multiple arthritis. Chorea and severe pericarditis developed with endocarditis, and death occurred after barely four weeks' illness. There had been a previous attack of rheumatic fever at five years of age. The post-mortem investigation showed pericarditis of the usual rheumatic type.

Dr. F. H. Thiele, clinical pathologist to University College Hospital, obtained a pure growth of a diplococcus from the heart's blood. Dr. T. Lewis demonstrated a diplococcus in the pericardial fluid. We also found it in the exudation, and in the laboratory it conformed to the characters of the diplococcus rheumaticus, and on experiment produced multiple arthritis and pericarditis of the usual type.

Example No. 2.—In June, 1908, Dr. J. Graham Forbes, bacteriologist to the Hospital for Sick Children, Great Ormond-street, isolated a diplo-streptococcus during life from the blood of a child in the hospital suffering from carditis, chorea, and nodules. This diplo-streptococcus had the usual appearances and growth on culture. Dr. Forbes kindly sent us a subculture and with it we repeated an experiment we have undertaken before—the subcutaneous inoculation of a large dose of the

culture. No suppuration resulted and in a short time all signs of an inflammatory reaction had disappeared as in our previous experience.

It is interesting that the subcultures from this case growing on unsuitable media showed a transition of the diplococcus into bacillary forms. Those who have followed the researches upon Achalme's bacillus will remember that in the last few years it had been observed this bacillus may assume a diplococcal form.

Example No. 3.—Dr. A. Salisbury Macnalty, resident medical officer at the Brompton Hospital for Diseases of the Chest, in April, 1909, kindly sent us a culture of a diplococcus which he had isolated post mortem from a case of rheumatic pericarditis. This micro-organism showed the usual characters of the diplococcus rheumaticus and produced a transitory arthritis of the right knee-joint on intravenous inoculation into a rabbit.

Example No. 4.—In August, 1909, through the kindness of Dr. Lauriston Shaw and Dr. A. F. Hertz from Guy's Hospital, pericardial and cerebro-spinal fluid were taken from a case of fatal rheumatic hyperpyrexia and were forwarded to us in sterilised sealed tubes; the results are fully detailed later in this paper.

We believe that these examples will dispose of any suspicion that our success in isolation of the diplococcus is dependent upon some mysterious chance, and we need only recall the work of Ainley Walker, Vernon Shaw, and Beattie in this country to make it clear that the diplococcus is not a monopoly.

With regard to the specificity of this micro-organism we would again repeat that in our experience no other can be found in the rheumatic lesions in man which will produce similar lesions in animals. Undoubtedly various micrococci may, for example, produce experimental endocarditis, as they may also produce endocarditis in man, but various micrococci are not found in human rheumatic endocarditis which will reproduce the disease. Again, various infections may cause experimental pericarditis, but only one in our experience can produce rheumatic pericarditis in man and also experimental pericarditis. We hold, too, that Triboulet, Wassermann, Walker, Vernon Shaw, Beattie, and ourselves have shown that the general characteristics of this streptococcus are as well differentiated as those of other members of this group. It would, nevertheless, be wrong to ignore the recent investigations by Rosenthal and others in France upon Achalme's bacillus, or to hide the fact that they claim that they have proved its causal relation to the disease. We can only repeat that we have failed to demonstrate this bacillus, and would add that even the French observers lay stress upon its pleomorphism and its occurrence in *diplococcal form.* Thus Rosenthal[6] mentions the reception of a diplococcus from Belgium which had been isolated from the blood of a case of active rheumatism. This, when transferred to his anaerobic media, developed into the bacillus of Achalme, but in aerobic culture it retained its diplococcal form. Rosenthal and others each year that passes are apparently striving to prove that this diplococcus is the bacillus of Achalme growing in unsuitable media. We, on the other hand, maintain that the diplococcus grows naturally in aerobic media, but may, as we stated eight years ago, when growing in unsuitable media, assume bacillary forms. Whether these bacillary forms are Achalme's bacillus we cannot say.

In this country we believe the tendency has been to mystify the main question—the etiology of rheumatism—by introducing a classification of the streptococci by certain sugar ferment tests in the laboratory. Apparently, as an outcome of this, we have to be satisfied with the description of a streptococcus salivarius or fæcalis. That a streptococcus in the saliva or fæces should give certain tests in the laboratory is not likely to be of any practical moment unless some peculiar streptococci develop *de novo* in these situations. Seeing that the nature of this group of micro-organisms is much altered by the media in which they grow, such a classification is in our present state of knowledge most perplexing. Instance, for example, the diplococcus of rheumatism: it undoubtedly locates itself in the tonsils, but are not these washed by the saliva, and is not the saliva swallowed into the stomach and passed into the intestines with the food? Which is of the greater importance—that a diplococcus can be isolated from a rheumatic angina and reproduce rheumatic lesions, or that a diplococcus isolated from the saliva and fæces can give some apparently specific sugar tests in a laboratory? Lastly, what alterations in character and virulence might not the diplococcus undergo when, dislodged from the tonsils by the saliva, it lingers in a new environment such as the fæces?

[6] La Tribune Médicale, Feb. 26th, 1910, p. 134.

Is it not an outcome of the confusion which arises from such a classification that in a valuable paper on infective endocarditis we read as follows: "It would obviously be fallacious to conclude that any micro-organism isolated from the blood of a patient with fever, endocarditis, and chorea had any necessary connexion with the cause of rheumatic fever"? Seeing that a streptococcus isolated from acute rheumatic lesions, and let us add also from the blood in acute rheumatism, can produce endocarditis, fever, and choreiform movements, as more than one skilled bacteriologist has shown, it is difficult to see how the conclusion that this streptococcus has some necessary connexion with rheumatic fever can obviously be fallacious. It may be a wrong conclusion but it seems almost a reasonable one.

Indirect Support from Recent Investigations.

We would next point out that in the last ten years the trend of scientific investigation and clinical observation has strengthened our position in spite of the fact that some of these observations have been made by those who have not had the causation of rheumatism in view, and others have been made by those who have not accepted our explanation and yet have been of assistance in bringing us support by their independent observations.

To take the first type of evidence, we would allude to a paper written by one of us in 1898 and read at the Royal Medical and Chirurgical Society.[7] In this contribution it was demonstrated that in rheumatic carditis scattered foci of inflammatory change were to be found in the connective tissue framework of the heart springing from the region of the small blood-vessels. It was further shown that in these regions gross changes might be found in the neighbouring muscular fibres. This distribution, it was pointed out, strongly favoured the view that they were a result of some bacterial infection. Later, when we identified the infection, we produced and showed at the Pathological Society of London experimental carditis of the same order.[8] These observations have been expanded, notably by Aschoff and Tawara[9] and Carey-Coombs,[10] who have maintained that they are specific lesions, and their importance has been insisted upon from an entirely different standpoint to ours. We emphasised their importance as a factor in the heart failure of rheumatic morbus cordis. Others, led by Dr. James Mackenzie, have dwelt upon their importance in connexion with cardiac arrhythmias and the primitive cardiac muscle. If we recall that Keith, in one of his latest papers which he read upon the anatomical side of this question before the Medical Society of London in 1909, stated his conviction that cardiac nerve and cardiac muscle come into such close relation that they may fairly be said to merge in the primitive muscular fibre of the cardiac tube, it becomes at once apparent that these focal lesions of rheumatic carditis must have an important bearing upon this aspect of cardiac disease.

Since Aschoff published his observations they have attracted considerable attention in this country not because of their bearing upon the etiology of rheumatism, but because they are concerned with the ever fascinating problem of the heart beat.

Next we will take the second type of evidence supplied by others who are opposed to our explanations, but who in spite of this have given us indirect support.

To us there are few more curious points in the history of cardiac pathology than the attitude held by many toward rheumatic endocarditis. They admit it is infective; the evidence, indeed, in its favour is overwhelming, but they hesitate to admit that this endocarditis may become malignant. When, however, we analyse the meaning of this malignancy as applied to endocarditis, we find it expresses an inability on the part of the damaged tissues to overcome the local infection. There may be partial, and exceptionally even complete, success, but the rule is failure. This malignancy is, then, no new mysterious change in the tissues, and as its antecedent we find the most frequent is previous rheumatic endocarditis.

Now come the curious conclusions we are asked to accept: firstly, that an infection in the endocardium of rheumatic origin is always simple—that is, is always capable of

[7] Poynton: Transactions of the Royal Medical and Chirurgical Society, vol. lxxxii., 1899.

[10] Quarterly Journal of Medicine, vol. ii., No. 5.

healing; and, secondly, that malignant endocarditis after rheumatism is always caused by a secondary infection of valves scarred by previous disease.

The first conclusion is strange, because infections of the rheumatic type are not likely to be always "simple"; they obviously vary in virulence as do all other infections of the same group. The second conclusion that bacteria prefer scarred valves is, in our opinion, a false one. There is no evidence that bacteria prefer scar tissue; in fact, all evidence is against it. If the so-called scarred valves of rheumatism are examined it will be found that the vegetations are not really scar tissue, but are masses of unhealthy necrotic material which the scar formation has not invaded. We hold that in this necrotic tissue the rheumatic infection that caused the original endocarditis often lurks quiescent but not destroyed. The formation of scar tissue makes it difficult for leucocytosis to deal with bacteria in these isolated necrotic patches, which, bordering as they do on the general circulation, are as much a source of danger as a necrotic gland close to the circulation is in tuberculosis.

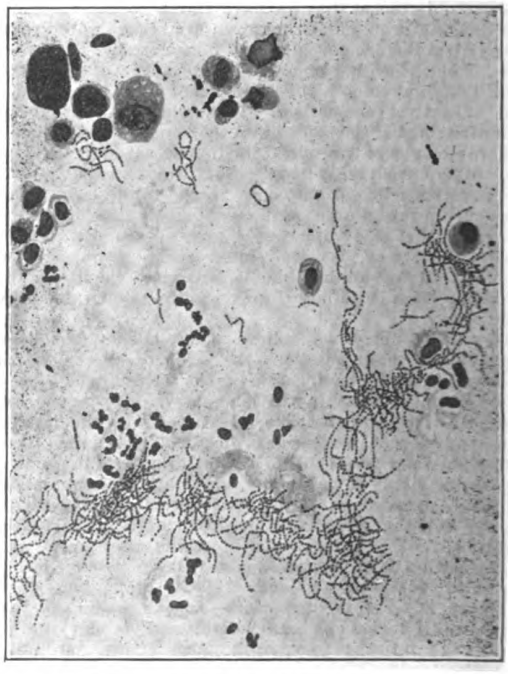
The recent vegetations of rheumatism are, in our opinion, often much more chronic than is generally believed, and those who investigate them from this point of view will find in them areas of necrotic tissue shut off by scar tissue—that is, they will find imperfect healing. We believe that in cases of malignant endocarditis of rheumatic origin the disease has been slightly active long before symptoms call attention to the serious nature of the disease. This link in the chain of evidence is difficult to get, but doubtless it will be obtained by clinicians who keep a constant watch on their patients who leave hospital with rheumatic heart disease. When in these cases the malignant type arises it is not necessarily because some added infection has attacked scar or sclerotic tissue, but because some agency lowering the general health has aroused the lurking micrococci of a previous infection which are lying in the necrotic areas bordering on the general blood stream.

In our original paper[11] we could not hazard how many cases of malignant endocarditis were rheumatic, but we thought future experience would show that a very considerable percentage would prove to be of this type. We are thus interested to find Dr. T. J. Horder discovering that the type of streptococcus most often found in infective endocarditis is not the highly pathogenic streptococcus of suppurative processes, but what he terms "one or other of three types of streptococci that are more closely allied to the 'saprophytic' streptococci of the alimentary canal." Dr. Horder[12] writes in terms of salivarius and fæcalis which unfortunately we cannot follow, but we note also that in an analysis of 100 cases of infective endocarditis he finds a streptococcus was present in 62. We hold that all complete evidence goes to show that the streptococcus which causes acute rheumatism is a cause also of malignant endocarditis, and that the further evidence in this condition of the frequent occurrence of "streptococci," which for want of a better description from others we may call peculiar, is an additional support to this view.

We would add that since our first contribution to this question we have seen further cases in adults and children which confirm our original examples and entirely support the view that rheumatism may be a cause of malignant endocarditis.

Acute Rheumatism and Rheumatic Fever Faulty Terms.

The next point we would emphasise is the retarding influence that the terms acute rheumatism and rheumatic fever exert upon the study of rheumatism. If we compare any one other great infection to rheumatism in its clinical course it would be tuberculosis. This is but a repetition of a former statement, but we allude to it now because it is so thoroughly supported by a recent paper by Dr. R. Miller[13] upon chorea. In this paper the writer dwells upon the fact that the choreiform movements are but the developed disease, and that there may be warnings weeks before these appear. The late Dr. W. B. Cheadle, Sir Thomas Barlow, and Sir Dyce Duckworth have called attention to the same point. This premonitory stage is not peculiar to chorea, for heart disease and arthritis show the same features. Many cases in childhood which develop obvious rheumatism may suffer for some weeks from fever, anæmia, and debility before anyone can foresee the exact meaning of these symptoms, a point which, we may add, Dr. G. H. M. Dunlop has also insisted upon. How can we, in face of these facts, keep the terms acute rheumatism and rheumatic fever as indicative of anything but phases of rheumatism? We have no doubt that a good deal of the mystery of unexplained heart disease, and in particular mitral stenosis, is the result of this imperfect naming of the disease. It is essential that some more general term such as rheumatism, which implies neither acuteness nor chronicity, should be used.



Rheumatic Hyperpyrexia.

Hyperpyrexia is an event in rheumatism which all would point to as one which should throw light on the pathology of the disease. Through the kindness of Dr. Lauriston Shaw and Dr. A. F. Hertz we have had assistance from Guy's Hospital upon this question. Until this recent opportunity we had only one case for investigation, and that not a classical example. It was fully published by us in THE LANCET in 1905,[14] and was peculiar in that there was severe cerebro-spinal meningitis. In the exudation there were great numbers of strepto-diplococci, and we satisfied ourselves, but we fear not others, that it was a rheumatic case. There is no necessity to recount the details of that investigation here. Our second from Guy's was of the classical type, the patient, an adult, dying with a temperature of 107° F., and the post-mortem examination showing active rheumatism but no meningitis. The following details give the salient features of this investigation.

The following tubes, among others, were received from Guy's Hospital on August 13th, 1909: (1) the turbid pericardial fluid in a sterilised pipette; (2) the blood; and (3) portions of the cerebral cortex. The two latter were placed in bouillon. The pericardial fluid was incubated overnight without addition of any medium.

The following results were obtained. A pure growth of strepto-diplococci was present in the incubated pericardial fluid (Fig. 1). The *cerebral cortex* gave a growth of diplo-

of the cerebro-spinal fluid showed a few diplococci. A film of the pericardial fluid showed the diplococci in streptococcal chains and in considerable number.

On August 15th two intravenous inoculations were made into rabbits. No. 1 received 30 drops of the pericardial fluid. No. 2 received 20 drops of the bouillon culture from the cerebral cortex which contained some colonies of staphylococcus aureus with the diplococcus. The second rabbit died in 24 hours from acute pericarditis, and the pericardial fluid from this, inoculated overnight, showed a pure growth of strepto-diplococci (Fig. 2). The other organs showed no

Incubated rabbit pericardial fluid (× 1000). Showing the streptococcal form of the micrococcus growing, as in Fig. 1, in streptococcal chains. This film is under higher magnification than Fig. 1, which was intended to show the exudation as well as the micrococci, and required a larger field.

obvious change. They were not soft and there were no hæmorrhages. The first rabbit lived a week and during that time it rapidly wasted and developed pyrexia, endocarditis, and arthritis of the right knee-joint. The post-mortem examination showed early endocarditis of the tricuspid valve, a fibrino-plastic exudation in the right knee-joint, and an infarct in the right kidney. Cultures from the right knee-joint gave a pure culture of strepto-diplococci.

A third rabbit was inoculated intravenously with 10 minims of the incubated pericardial fluid from rabbit No. 1. Three days later there was arthritis of both shoulder-joints with wasting and general illness, but during the next week there was gradual recovery from the arthritis. This animal died from acute intussusception 12 days after the injection, and the post-mortem examination showed no cardiac lesion and a healing arthritis.

A fourth rabbit was inoculated on August 25th with a culture from the cerebro-spinal fluid. On the 28th the right knee became swollen and tender and the animal began to waste. No cardiac lesion was detected.

Examination of fragments of the aortic and mitral valves, portions of the motor cortex and pia mater of the patient showed that the valvular lesions were of old standing and that the brain and pia mater examined only showed a few diplococci.

The result of this investigation may be thus summarised: From a case of rheumatic fever with carditis, arthritis, and hyperpyrexia a strepto-diplococcus was obtained in pure culture direct from the pericardial fluid incubated overnight. This strepto-diplococcus produced, on intravenous inoculation into rabbits, non-suppurative multiple arthritis, pericarditis, endocarditis, and infarction, and the micro-organism was again isolated from the lesions in pure culture. The same micro-organism was present in the cerebro-spinal fluid, motor cortex, and blood of the patient.

It would be a mistake to infer too much from a single case, but we believe this investigation supports the general opinion among physicians that rheumatic hyperpyrexia is a peculiar toxæmic process rather than an intense bacterial invasion, for although the micrococci were both isolated and demonstrated, they were not present in the tissues or blood in any extraordinary numbers.

Investigations upon the Tonsils in the Rheumatic.

Two other lines of investigation have occupied our attention in the last five years: the first is another step in the study of the tonsils suggested to us by Mr. George Waugh; the second is an experimental study of arthritis, with a view to ascertaining whether more than one form of arthritis may result from intravenous inoculation of the same micro-organism. The object of this second investigation is to widen the field of study of rheumatoid affections, reversing, as it were, the usual method of inquiry. The clinician seeks among this heterogeneous group to find some one clear path. We have started along one clear path (the study of the diplococcus) and endeavoured to find our way some little distance into this heterogeneous group.

Taking first the tonsils in rheumatic fever we need only mention the great frequency of tonsillitis in this disease, and the demonstration by Dr. William Hill[15] some 20 years ago of deep-seated foci of disease in enlarged tonsils removed from the rheumatic. In 1900 we showed that a micrococcus found in rheumatic lesions could be isolated from acute rheumatic angina, and be demonstrated in the tonsils, and further would produce similar lesions. In the next year Fritz Meyer published an extensive paper upon the same subject, and we have returned to the question again to work out Mr. Waugh's suggestion. Mr. Waugh advocates enucleation of the large unhealthy tonsils that are so often present in rheumatic children, and in some carefully chosen cases has done this for us between the rheumatic attacks. These tonsils were seared on removal, cultures were taken from their depths, and the histological appearances of them investigated. One example will suffice to show the kind of case investigated, six cases of which have been examined up to the present date.

The patient, a male aged 10 years and 5 months, came to the Hospital for Sick Children, Great Ormond-street, in February, 1908, suffering from slight chorea and rheumatic pains. In 1906 he had an attack of rheumatic fever, since which he had never quite recovered his usual health, and had always had shortness of breath on exertion. The heart was obviously affected. There was considerable mitral regurgitation, with hypertrophy and dilatation. In addition he had two very large tonsils and was subject to sore-throats. The cervical glands showed a moderate enlargement. In April, when quite recovered from his active rheumatism, Mr. Waugh enucleated both tonsils. Immediately after removal the surface was seared, and cultures were taken from the centre of one gland. Histological examination by section and films of the other tonsil showed the presence of streptococci in the deep part of the gland. The culture gave an almost pure growth of strepto-diplococci, from which it was easy to isolate this organism in pure culture. Five minims of this culture injected intravenously into a rabbit produced no result. Two cubic centimetres produced arthritis and fatal aortic endocarditis. One cubic centimetre in another experiment produced arthritis of the left knee, which slowly recovered. Subsequently smaller doses produced arthritis of the right knee-joint and fatal endocarditis.

We have here but a repetition of the results obtained in our original case in 1899, and independently confirmed by Fritz Meyer[16] in 1901. The particular point of interest lies in the fact that here we are dealing with tonsils in the rheumatic when they are not in the stage of acute inflammation, during an attack of acute rheumatism, but in the latent period after previous attacks of the disease.

There can be very little doubt, we believe, that these large unhealthy tonsils are a constant menace to the rheumatic, and that these investigations originated by Mr. George Waugh show decisively that there abound in the depths of these disordered tissues strepto-diplococci which will produce with much constancy in appropriate dosage endocarditis, pericarditis, and arthritis on intravenous injection into

[15] Tonsillitis in Rheumatic States, 1889.

[16] A paper read before the Congress of Internal Medicin, Berlin, 1901.

rabbits. We believe they may well explain some rheumatic relapses. The relation of acute rheumatism and tonsillitis to the diplococcal infection is now so well-defined by clinical observation, histological investigation, and experimental research that it constitutes one of the most satisfactory advances in the study of the disease. We have only to contrast the explanation it gives us with the older nervous and lactic acid theories to realise this advance, which is one, not only of scientific interest, but also of practical importance. We have not investigated other pathways of infection, but great attention has been directed to the importance of unhealthy condition of the teeth. It would be wrong to deny, too, the possibility of infection from the alimentary canal, but we do not think that at present the wide acceptance of auto-infection from the intestines in arthritic diseases has as yet been completely justified by the evidence that has been forthcoming, however probable it may seem on clinical grounds.

When the position of the tonsils is borne in mind it may seem a startling assertion to make that strepto-diplococci may be obtained in pure culture from the depths of the diseased glands, yet it is true, and has happened not only in our experience but in one case was quite independently ascertained by Dr. Graham Forbes, who had examined a culture from the same case.

We are not pretending that a pure culture is a constant result, but we have invariably found that the strepto-diplococci predominated. Again, we do not deny that the same results, both cultural and experimental, might obtain if diseased tonsils from the non-rheumatic were treated in the same way. We have not worked at this point. Should similar results obtain it would not negative the interest of the facts before us, for it is quite evident from our clinical knowledge that there must be a tendency to develop rheumatism, and we have never believed that the exciting cause was not present in the normal throat. As with tuberculosis and pneumococcal infections, so with rheumatism, there are many factors to be considered in addition to the presence of a bacterium.

Investigations upon Arthritis.

When the diplococcus of rheumatism is injected intravenously it produces arthritis with great frequency; and further we have convinced ourselves that it may produce it in various forms. In 1902[17] we published with drawings in the Transactions of the Pathological Society a short paper upon the production of an osteo-arthritis—non-suppurative in character—by the intravenous inoculation of a micrococcus isolated from a case of human osteo-arthritis in which death had occurred from misadventure. We believe this to have been the first recorded example of experimental osteo-arthritis by intravenous inoculation. Since that date we have produced osteo-arthritis and peri-articular arthritis with the diplococcus rheumaticus, and at the present time we have a very striking specimen of an arthritis resulting from this infection. This occurred in a rabbit which had developed inflammation first of one knee-joint and then of the other, from which it gradually recovered, but 18 months later, though in good health, it limped to some extent upon the hind limbs. This specimen showed that there was a clear fluid in both articulations, but the right patella was dislocated and had formed for itself a new facet on the inner side of the internal femoral condyle and the original facet had lost much of its cartilage, and the bones had been eroded. The left joint showed erosion of cartilage. The occurrence of dislocations of joint surfaces in human "rheumatoid arthritis" is well recognised, and the production of such a deformity is strictly analogous to the condition in the specimen just described, in that there are in both a stretching and damaging of the capsules of the articulations by a non-suppurative process, a damage to the articulating surfaces themselves, and a faulty pull of tendons connected with the joints. At the British Medical Association meeting at Manchester we also demonstrated convincing examples of the "guttering" of osteo-arthritis, and published illustrations of these changes in a paper in the *Medical Press and Circular*.[18] In this paper we also showed that perivascular fibrosis occurred in the capsules of articulations, the subject of experimental and pathological chronic arthritis, explaining thereby the "withering" of joints in rheumatoid affections. We have also produced that rarefying osteitis of bone ends in the neighbourhood of joints affected by chronic disease which is well recognised in "rheumatoid arthritis." Although so far as we can judge from modern writings and discussions the results that we have already published have aroused but little interest we cannot help thinking that the fact that a micro-organism can, on intravenous inoculation, produce all these various forms of arthritic change must in the course of time persuade many to look upon "rheumatoid affections" in a more tolerant spirit. At present the statements that meet one are somewhat of this nature. "Rheumatoid arthritis" is quite different from rheumatic arthritis; or put as an interrogative, Do you suppose that all "rheumatoid arthritis" is rheumatic?

Investigations of this nature do not pretend to settle such problems, but they do warn us not to classify "rheumatoid affections" by the character of the arthritic lesions, and not to persist in stating dogmatically that acute rheumatism produces a transient arthritis. For ourselves, we believe that just as malignant rheumatic endocarditis is probably a more frequent occurrence than is generally believed, so also, too, is malignant rheumatic arthritis.

We will not again labour here the obstructing influence that we believe the view that salicylate of soda is specific exerts upon advances in the study of rheumatism.

Two further clinical points of minor importance from the scientific view have engaged the attention of one of us. The first is the age at which a rheumatic infection may occur. It seemed to us remarkable that it should delay its appearance to the fifth year and later, for there seemed to us nothing unusual about the general characters of the infection that demanded such a strange limitation. In a paper published in 1908[19] it was shown that rheumatism is by no means rare in the very young, although infancy, being protected by its helplessness from exposure, is to a great extent immune. Thus any difficulty upon the score of age in regarding rheumatism as an infection is groundless.

The second point was an investigation into the after-history of scarlatinal rheumatism in a paper published in 1909.[20] It was shown that most, and possibly all, of these cases are examples of true rheumatism, probably modified to some extent by the mysterious condition we call scarlet fever.

In conclusion, we would repeat that no explanation of acute rheumatism can, we believe, compare with that which attributes it to an infection with a diplococcus of the streptococcal group; and that although during the last ten years this view has gained but little headway in this country the Chelsea Clinical Society in 1900 marked a forward step in London when they opened a discussion on "Acute Infective Rheumatism."

TWO CASES OF NEPHRECTOMY.[1]

BY R. ATKINSON STONEY, F.R.C.S. IREL.,
VISITING SURGEON TO THE ROYAL CITY OF DUBLIN HOSPITAL.

THE following two cases of nephrectomy are, I think, of sufficient interest to merit recording.

CASE 1.—The patient, a man, aged 28 years, while riding a bicycle down-hill on August 2nd, 1909, collided with a man and was thrown off his bicycle and fell on his right shoulder. He fell clear of his machine, and was not conscious of striking the ground except with his shoulder; he got up immediately, but fell down again and was unconscious for about ten minutes. He then went home, and half-an-hour after the accident he vomited. For the next week he remained very quietly in bed, suffering great pain under the ribs on the right side. The pain subsided somewhat, and the next week the patient was able to sit up in bed, and by the end of the week he was up and about, though he did not return to work. On the 19th—that is, the seventeenth day after the accident—he for the first time noticed blood in his urine. He brought a specimen to hospital with him, and as it was found to contain a large quantity of blood he was at once admitted to the Royal City of Dublin Hospital. The patient was quite positive that this was the first time since the

[1] A paper read at the Surgical Section of the Royal Academy of Medicine in Ireland on March 11th, 1910.

accident that he had passed any blood. During the first few days of his stay in hospital he passed what appeared to be nearly pure blood in large quantities, but on the 22nd he had a rigor, the temperature rising to 104° F., and there was retention; on passing a catheter the bladder was found to be distended with clotted blood. The temperature fell on the next day, but remained somewhat irregular. A few days later a catheter had to be passed again to break up clots in the bladder. On the 28th the urine was nearly clear and remained so for two days, but on the 31st, while the patient was being moved in bed to have his back rubbed, he felt a sudden pain in his right side, and the next urine passed contained a large quantity of blood and some clots. On Sept. 4th the urine was segregated by means of the Luys segregator. The urine from the left side contained no blood, that from the right appeared to be nearly pure blood. Since admission the patient had been passing from 40 to 85 ounces of urine a day, an average of 56 ounces for the 16 days during which he had been in the hospital. The patient was wasting rapidly and had become very anæmic. On the 6th there was only a trace of blood in the urine and the temperature rose again to 104° on the following day. His pulse had become much weaker during the last two days, and it was decided to operate on the 8th. A lumbar incision was made on the right side, and the region of the kidney was exposed. A thick layer of partially organised blood-clot behind the kidney was divided and the kidney was reached. In attempting to peel the peritoneum off the anterior surface of the kidney a rent was made in it, and it was found impossible to separate it, so an incision was made through the capsule of the kidney and this was peeled off with the peritoneum towards the hilum. In enlarging the wound so as to allow access to the upper pole of the kidney the pleural cavity was opened, although the incision was kept well below the angle between the last rib and the outer border of the erector spinæ; the opening was at once plugged with gauze, held in place by a retractor. The kidney was now freed and was found to be almost divided in two near the level of the hilum, and the lower half to be largely disintegrated and merely represented by a mass of blood-clot. The pedicle was divided from above downwards, the vessels being clamped one after another as they were exposed and cut; there was comparatively little bleeding during this process. The vessels were then tied with catgut, and to stop some oozing a few deep catgut sutures were used to unite the anterior and posterior parts of the kidney capsule. The rents in the peritoneum and the pleura were stitched, a piece of gauze was passed down to the remains of the kidney capsule, and the muscles were sutured with catgut and the skin with silkworm gut. The patient was given two pints of saline solution subcutaneously during the operation. He made an uninterrupted recovery. The gauze was removed on the fifth day and the stitches on the seventh, the wound healing rapidly. There was no more blood in the urine after the day of operation, and the cystitis which had been present before operation gradually cleared up. On the day of operation the patient passed 42 ounces of urine and on the following day only 24 ounces, but on the next three days over 50 ounces were passed daily, and from then to the time he left the hospital the average was 43 ounces. The patient left the hospital on Oct. 9th for the convalescent home, and when seen in the middle of November he was quite well and had put on over a stone in weight.

The history in this case is hard to explain. Why, when the kidney was so severely injured, was there no blood in the urine for more than a fortnight? Why, when the kidney was nearly torn in two and the calyces opened, was there no extravasation of urine or the formation of a perinephric abscess? How was so much damage done to the kidney, so that the lower half of it was pulped by a fall on the shoulder? And, lastly, why, with such severe injury, was there nothing more than pain in the side? The following is the probable explanation of the course of events. When the patient fell on his shoulder the trunk was forcibly bent to the right and the kidney, especially the lower pole, was crushed between the last rib and the crest of the ilium, blood was extravasated into and around the kidney and clotted in the ureter. The injury to the kidney was so great that suppression of urine occurred on this side, so preventing urinary extravasation. When the patient got up and began to move about at the end of a fortnight the clot in the ureter was dislodged, as were those in the torn vessels, and hæmaturia, for which the patient was admitted to hospital, occurred; about this time also the remainder of the kidney began to secrete again. On at least two occasions during the patient's stay in hospital before operation the ureter again became blocked by clot and the hæmaturia ceased temporarily. The adhesions formed made the operation difficult and precluded the possibility of isolating and clamping the pedicle before removal. Fortunately the opening of both the peritoneal and pleural cavities was not followed by any unfavourable results. The pleural reflexion was abnormally low, crossing the last rib below, where it was met by the outer border of the erector spinæ, instead of above this point as is the normal arrangement.

CASE 2.—The patient, a woman, aged 27 years, noticed blood in the urine on May 14th, 1909, after a severe chill. She also complained of some pain in the left side. She remained in bed for three months, and the urine, which was frequently tested, always contained some blood. Tubercle bacilli were also found. During the months of August and September the patient was up and went about a little. She had pain in the left side and the back, never in the groin or thigh, and never noticed pain when passing urine. Since the beginning of October there has been more blood in the urine and the pain has been worse. She was admitted to the Royal City of Dublin Hospital on Oct. 6th. She was a well-nourished, healthy-looking woman, and had increased 5 pounds in weight since the beginning of August. There were slight pain and tenderness on pressure over the lower pole of the left kidney, which was thought to be palpable. The urine was red in colour, containing blood in large quantity and pus. Tubercle bacilli were demonstrated in the urine. On the 9th the patient was anæsthetised with ether and the urine was segregated with Luys' segregator; the flow of urine was very slow and the amount collected small, but that from the right side contained no blood, while that from the left side did. On the 16th the urine was again segregated. This time the patient was not anæsthetised. A pint of weak tea was given half an hour before, and a pint of milk and soda-water during, the procedure. In the course of about 40 minutes 11 drachms of urine were collected from the left side and 8 drachms from the right side. The urine from the right side came in gushes of three or four drops at a time, was quite clear, and contained no pus or blood; that from the left side came in gushes of five or six drops at a time, contained blood and pus, and tubercle bacilli were demonstrated in it under the microscope. From the time the patient entered the hospital till the time of operation, although she was left absolutely quiet in bed, the amount of blood in the urine did not diminish but was always considerable. Nephrectomy was therefore performed on the 26th. The kidney was exposed by the lumbar route. It was found to be very freely moveable and somewhat larger than normal, and a cavity of the size of the top of one's finger could be palpated in the upper part. The pedicle was clamped and the kidney was removed. Unfortunately, in transfixing the pedicle preparatory to ligating it the blunt needle pierced one of the branches of the renal vein and there was some difficulty in stopping the hæmorrhage. The vessels were finally tied separately with silk, but a clip had to be left on one bleeding point. The clip was removed on the fourth day and the stitches on the eighth, the portion of the wound which was not sutured on account of the presence of the clip healed rapidly, and the patient left hospital for the convalescent home on Dec. 1st. There had been no blood or pus in the urine since the operation and a microscopic examination failed to demonstrate the presence of tubercle bacilli. Before operation the patient was passing a daily average of 45½ ounces of urine, and although for the first six days following the operation the average was only 22½ ounces a day, the amount then rapidly increased, and the average for her stay in hospital after operation was 48¼ ounces, a little more than the amount excreted by both kidneys before the operation. On splitting the kidney open it was apparently normal, except for a cavity in the upper pole which practically corresponded to one of the pyramids; it was smooth-walled and had a capacity of about half a drachm. Over a small area the wall was slightly nodular and suggested the presence of tubercles. Sections were made of portions of the wall and were examined, but the microscopical appearances were not definite, though very suggestive of tubercle. No giant cells were seen but considerable round-celled infiltration and

closely packed masses of round cells here and there. When seen on her return after a fortnight's stay at the convalescent home the patient was looking well and had put on 8 pounds in weight.

This case also is peculiar from the disparity between the symptoms and the pathological findings. For here, though the disease had lasted for about six months and was marked by the constant presence of blood and pus in large quantities, it was limited to a very small portion of the kidney. If a partial nephrectomy for tubercular disease is ever justified, which is denied by some of the best authorities, this certainly would have been an ideal case for such treatment.

Dublin.

A CASE OF VOLVULUS ASSOCIATED WITH THE REDUCTION OF A HERNIA.

BY GORDON TAYLOR, M.A. ABERD., M.S., B.SC. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON, THE MIDDLESEX HOSPITAL.

VOLVULUS occurring in connexion with hernia was somewhat recently the subject of a leading article in the columns of THE LANCET, and in the same number four recent cases of the condition were recorded by Mr. Lawford Knaggs [1] and two cases by Mr. J. F. Dobson,[2] all six cases having been operated upon in the Leeds General Infirmary. The condition does not appear to be very common, and its comparative rarity, quite apart from the somewhat curious history associated with the present case, would seem to justify its publication. Mr. Lawford Knaggs in his excellent articles in THE LANCET and in the *Annals of Surgery*,[3] classifies the cases of volvulus associated with hernia into the following four groups: (1) the contents of a hernia or a part of them are twisted, the neck of the volvulus lying either within the hernial sac or at the hernial aperture; (2) a volvulus is present, and its neck with some of the affected coils of intestine lie within the abdomen, but a loop of coil belonging to the twist is engaged in the hernia; (3) a volvulus may be produced within the abdomen by the reduction of a hernia; and (4) a volvulus may occur within the abdomen from some predisposing condition more or less directly connected with a hernia.

Most of the cases on record appear to belong to the first two groups, and the cases detailed in THE LANCET of March 6th, 1909, can all be referred to the second class. The history of the present case rather suggests that it belongs to the third group of cases, which is a small one, Mr. Lawford Knaggs referring to only two cases coming under this heading.

A woman, aged 69 years, unmarried, had for a number of years suffered from a right inguinal hernia for which she had worn a truss. Twice before the hernia had given rise to symptoms of strangulation, and on the first occasion medical aid had to be requisitioned to effect its reduction. On the second occasion the patient herself, with a good deal of pain and difficulty, succeeded in reducing the hernia and in obtaining immediate relief from her symptoms. On April 3rd, 1909, while the patient was in her bath, the hernia again came down, producing great pain and nausea. Difficulty was again experienced in reducing it, but the patient and her sister, acting with some vigour, and supplementing the manipulations of their fingers with the pressure of the truss, after some hours again succeeded in effecting the disappearance of the swelling, but instead of the relief from pain experienced on previous occasions the latter at once became much worse. When seen by her medical attendant on the following day she complained of pain all over her abdomen, most intense, however, in the right iliac fossa. The bowels had not moved since the attack commenced, and vomiting occurred as soon as food was attempted; general abdominal tenderness was present, but no swelling could be made out in the inguinal canal. Despite her serious condition, which was repeatedly pointed out to her by her medical attendant, the patient persistently refused operation until late in the evening of April 7th, by which time the vomiting had become very urgent and stercoraceous. She was admitted to hospital in the early hours of April 8th; a tense painful swelling was then to be felt in the right inguinal region which gave no impulse on coughing. In spite of the fact that the patient had now been ill for over four days the pulse-rate was only 100 and the temperature was just above normal. The diagnosis was made of a Richter's hernia with gangrenous bowel, and a spreading peritonitis starting in the right iliac fossa.

Operation was performed as follows. An incision was made over the right inguinal canal, and some blood-stained fluid with a most filthy odour escaped from the hernial sac. No gut was found occupying the neck of the sac, but on introducing a director through the internal ring a quantity of foul purulent fluid escaped, and a large mass of boggy intestine could be felt just inside the ring. The abdominal cavity was opened and a large volvulus found in the right side of the abdomen consisting of upwards of 5 feet of the lower ileum. The gut had rotated from right to left through an angle of about 180°, and it was found impossible to untwist it; the bowel was in a gangrenous condition, perforated in several places, and the surrounding peritoneum acutely inflamed. Several ounces of stinking purulent fluid similar to that which escaped through the internal abdominal ring were found to occupy the pelvis and the right iliac fossa. The gangrenous portion of the bowel having been resected with about 6 inches of healthy bowel on each side, the ends of the proximal and distal segments were closed in two layers with a suture of No. 60 linen thread, and a lateral anastomosis then effected. Before suturing the bowel the proximal segment was brought out of the abdominal wound and a considerable quantity of the intestinal contents allowed to escape. The abdomen was closed with through-and-through sutures of silkworm gut, two drainage-tubes being inserted through the original incision, one into the pelvis and the other into the iliac fossa.

For a fortnight the patient made excellent progress; the bowels acted regularly from the time of the operation, but a good deal of pus continued to escape from the drainage openings. On the fifteenth day small intestine contents began to escape through the original wound, and by the end of the third week practically no fæcal matter was passed by the rectum, and the skin became excoriated and painful despite applications of calamine lotion and ointments containing lead and bismuth carbonate. At the suggestion of the sister of the ward strips of linen soaked in parolein were applied to the excoriated abdominal skin, which rapidly improved under the treatment, and by May 18th was sufficiently sound to permit of further operative treatment being undertaken to cure the fistula. On May 18th, nearly four weeks having elapsed since the formation of the fistula, which showed no sign at all of closing, the abdomen was reopened and the ileum divided just above the site of the opening on to the skin. Each cut end of this part of the bowel was then crushed with an enterotribe [4] and the stump buried by means of a purse-string suture of thread; an anastomosis was then effected between the upper segment of the ileum and the transverse colon. Intestinal contents ceased to escape from the fistula, which now discharged only a little mucus, and on June 16th she was sent to the convalescent home at Clacton-on-Sea.

In the beginning of August the patient was re-admitted to hospital since the terminal segment of the ileum, which had been left at the second operation, tended to prolapse through the fistulous orifice; the patient's skin was constantly wet with mucus, the amount of which had greatly increased since she left the hospital in June, probably as the result of the irritation of the exposed bowel, and she was exceedingly anxious to be rid of the discomfort. On August 6th the abdomen was again opened and the terminal segment of the ileum from the fistula to the ileo-cæcal orifice, amounting to some 10 inches, was removed; the stump was crushed and buried in the cæcum. Two pedunculated sub-peritoneal fibroids, each of about the size of a tangerine orange, were removed at the same time. She made an uneventful recovery and left the hospital on Sept. 1st, 1909.

Despite the total loss of nearly 7 feet of small intestine and the exclusion of the cæcum, the ascending colon, and part of the transverse colon, the patient has remained in very fair health, and the bowels, which at first acted three, four, or more times in the 24 hours, now act twice a day regularly.

[2] THE LANCET, March 6th, 1909, p. 679.
[3] Annals of Surgery, April, 1900.
[4] Gray's modification of Doyen's enterotribe.

She takes food well, and except for the discomfort of a ventral hernia, for which she wears an abdominal belt, she may be safely said to be far more vigorous and active than the great majority of patients in their 71st year. It is, of course, possible that the case may really belong to Mr. Lawford Knaggs's second class, and that an intra-abdominal twist had already formed, and that acute symptoms were precipitated by one limb of the twist being pulled upon and becoming taut by incarceration in the hernia sac, but the fact that the symptoms immediately became much worse when the hernia had been reduced inside the abdomen rather points to the actual process of reduction having imparted a twist to the piece of bowel which had been lodged in the sac. The coils of the volvulus were so matted together by agglutinative peritonitis and shared so equally in the gangrenous process that the particular coil which had been engaged in the hernia could not be identified. There is evidence that elongation of the mesentery may result from repeated inclusion in the hernial swellings and, as Mr. Lawford Knaggs points out, it is reasonable to suppose that if a particular portion of the mesentery were in this way marked off from the rest the coil of intestine attached to it might easily fall into a state of volvulus from its two ends being brought more or less close together; in any case it might well act as a predisposing factor in the production of the twist, of which the misapplied taxis furnished the exciting cause.

The case can in no way be regarded as a triumph of surgical technique; the first anastomosis failed, possibly because the bowel at the suture line became softened by the suppurative process, and two operations had to be performed to restore its continuity. Although at the time of the first operation the resection of some 6 feet of small bowel for acute obstruction in an old woman of nearly 70 years seemed a desperate measure, yet the fact that her pulse before operation was only 100, that the peritoneum, containing as it did distinctly purulent fluid, was thereby exhibiting a very decided reaction, and that the proximal segment of the bowel was able to partly empty itself of its stagnant contents, thereby showing that it was not in that lethal condition of paralytic distension,—all these proved that one was dealing with a patient possessed of marked vitality, and to this and to the careful nursing her recovery is mainly due. The case illustrates one of the causes of the continuance of symptoms of strangulation after the reduction of a hernia by taxis—a recognised though not a common cause. The condition is mentioned in the last edition of an excellent and popular text-book of surgery,[5] where it is stated that the persistence of symptoms may be due to a volvulus having formed in the sac and having been reduced untwisted, or to the formation of an intra-abdominal volvulus after reduction owing to the paralysis of the bowel.

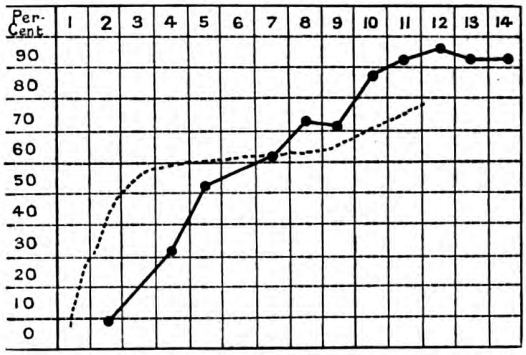
PULMONARY TUBERCULOSIS IN CHILDREN.

BY MARY HAMILTON WILLIAMS, M B., B.S. LOND., D.P.H. CAMB.,
SENIOR MEDICAL INSPECTOR OF SCHOOLS, WORCESTERSHIRE.



THE time has come when we must alter our conception of tuberculosis. We have grown up to consider it a fatal disease, generally killing its victims once it has obtained a firm foothold. When due regard is had for the fact that the large majority of British people have at some time of their life been infected with tuberculosis, we *ought* to regard it as a disease with an extremely low case mortality. Perhaps the disease to which it is best compared is gout. A fairly large number of people suffer from gout, and of these a few die from it. A man contracts gout and has an attack; then for a period, if he lives righteously, he does not suffer. Then, if he again sins, he suffers from a fresh attack; if he again takes care he recovers and enjoys good health in proportion to the care he takes and the degree of his disease. Substitute the word "tuberculosis" for the word "gout," and the description holds good for this disease also.

In a recent paper in THE LANCET[1] Dr. C. Riviere objects to the present use of the words "pulmonary tuberculosis" and "phthisis," and endeavours to limit and restrict the use of both words in accordance with certain ideas of his own. I agree with him in objecting to the use of the word "phthisis" as it is often used. The words "phthisis" and "consumption" have both acquired a sinister meaning, and imply the existence of a disease which will probably be fatal. Pulmonary tuberculosis is generally a non-fatal disease, and I think it would be much better if we used this title to indicate all cases of tubercular disease of the lungs, and at the same time do our best to prevent this word acquiring any significance which shall lessen by one iota the hope of long life to which a person with pulmonary tuberculosis may fairly look forward. Most of us have used the words "phthisis" and "consumption" hitherto because they were the words in common use. But it would be far better to drop them, as they embody a most mischievous idea.

The result of recent work shows that the tubercle bacilli are very widely disseminated. They are present in the large majority of people, but only do harm in a small proportion of cases. The first question naturally is as to when these bacilli gain access; and the results of post-mortem work and the most careful recent tests alike show that infection most commonly takes place in childhood. There are two tables on the subject of tuberculosis in children, given by different workers from different standpoints, which to my mind merit comparison. The one is a table[2] given by Hamburger and Sluka of the percentage results of 100 necropsies in children in regard to the number found tubercular at different ages. The other is the table[3] given by Hamburger showing the results of von Pirquet's reaction, together with a tuberculin test in certain cases. The two results are contained in the following chart:—

CHART 1.

Ages in Years.

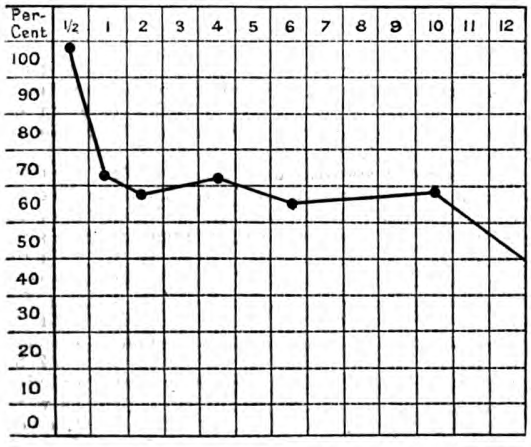
The continuous line shows von Pirquet's reaction. The dotted line shows results of 100 post-mortem examinations.

The results of other observers on the same lines tend to confirm the above chart. This chart shows unmistakeably that tubercular infection begins in many cases in early childhood, and its frequency increases steadily as the child approaches puberty.

In dealing with statistics of any nature it is of importance that deductions in regard to them should only be made in exact accordance with the basis on which the statistics were framed. In the paper by Dr. Riviere before alluded to there are certain absolutely unwarranted deductions. It is first shown that the Registrar-General's returns for 1907 show the deaths from "phthisis" between 5 and 14 years of age to be 3·1 per cent. of the total deaths. Dr. Riviere also states that the proportion of undoubted phthisis cases among his out-patients for the same ages is 2·6 per cent. of the total. He then compares the number living at the various ages, and continues: "If the phthisis were as rife at school age as in later life, 24·0 per cent. of cases would occur between these years instead of the 3·0 per cent. or thereabout of my figures *and those of the Registrar-General*" (italics are mine). But the Registrar-General by no means states that this is the proportion of *cases* of phthisis. From his figures may be correctly deduced the statement that the proportion of *fatal* cases of phthisis is 3·0 per cent. Dr. Riviere's out-patient figures are for cases of phthisis. The Registrar-General's are for fatal cases. There is no necessary analogy between the two, and, for reasons which I will explain later, it is not possible for there to be any analogy.

Dr. Riviere gives a table of post-mortem results recording tuberculosis in children. Though no reference is given, I find that this table occurs in the same paper from which I quoted last year. I did not use the table Dr. Riviere gives because the deaths mentioned there were from diphtheria and therefore referred mainly to children under 5 years of age. A reference to the chart given earlier in this paper will show that the maximum percentage of children infected with tuberculosis between 2 and 5 is the 60·0 per cent. of the 5 years old. After that age the percentage steadily rises, until by 12 years of age some 96·0 per cent. were infected. Hence it does not appear fair to deduce any conclusions in regard to school children from facts concerning children under 5 years. In the figures which I quoted *re* Hamburger and Sluka's own cases, the deaths had occurred from infectious diseases, trauma, or operations. The ages were as follows:—

	Cases.		Cases.
Under 1 year	154	5 years to 10 years... ...	57
1 year to 5 years	168	11 ,, ,, 14 ,, ...	22



Considering the fact that the percentage of infection is so very much greater in cases at the higher ages (of which there are only 22 in the table as compared with 399 under 10) I consider that this would more than balance any possible excess from any high figures which might result from measles or scarlet fever cases.

At the beginning of the excellent paper, above quoted, by Hamburger and Sluka, they state that Naegeli's figures must be included in any consideration of the subject, both on account of the detailed accuracy of the classification and the extreme care taken in the examination of the material. Many of the observers only examined macroscopically, and none, except Hamburger and Sluka themselves, analysed the results with the extreme care taken by Naegeli. (Unfortunately, Naegeli's figures are often incorrectly quoted—an error crept into an early quotation and has been re-quoted since.) The analysis made by Naegeli and that by Hamburger and Sluka are interesting in regard to the proportion of lethal cases among children with tuberculosis at the different ages.

Naegeli's figures give 100 per cent. lethal cases among children infected with tuberculosis at ages under 5 years; at ages 5 to 9, the lethal proportion is 75 per cent.; at ages 9 to 17, the lethal proportion is 40 per cent. Hamburger and Sluka's analysis[4] shows the same diminution in the proportion of lethal cases as the age increases. Shown in tabular form their results are as follows:—

CHART 2.

Ages in Years.

A comparison of this chart with the former chart shows plainly that it is false and inaccurate to deduce statements concerning the number of cases of tuberculosis from the number of deaths from tuberculosis. Apparently, as Dr. R. A. Young states,[5] "as age progresses more children suffer from tuberculous lesions, although decreasing numbers die from their results." Dr. Young also quotes Müller to the effect that in his cases of tuberculosis in children the lungs were affected in 92·67 per cent.; and other figures in his paper, quoted in my former paper, indicate that the figure is generally high, Dr. Young's figures being higher than those I quoted. But whichever set of figures we consider, the results show that so far no clinical observer has come near ascertaining the actual amount of pulmonary tuberculosis which exists in children.

Dr. Riviere's figures are too small to be of much use. But of the 21 cases of pulmonary tuberculosis (presumably not early, as he notes that symptoms appear late in children, and they would not be taken to hospital until they had symptoms) he only records a mortality which works out at 43·0 per cent. But the main reason why mortality statistics from any hospital are of little use is because most school children with pulmonary tuberculosis are not ill, and therefore there is no reason why they should attend a hospital. Hitherto we have considered that persons with tuberculosis were ill. Now that recent work has placed beyond dispute the fact that most people and most children are tuberculous, it is high time we ceased to think of a child with tuberculosis as necessarily needing a visit to a medical man.

In reports, letters, &c., on the subject of the discovery of pulmonary tuberculosis during the medical inspection of school children I have been repeatedly much distressed by the recurrence of phrases such as "in the short time at our disposal," "in a few minutes,"[6] &c., all used to show that pulmonary tuberculosis cannot be diagnosed owing to lack of time. If medical inspection of school children is to be more than a farce—and a farce disgraceful to the medical profession—we must insist on taking such time as we, each one, consider necessary for diagnosis. We cannot advise either our education authority, or the parents, of the many steps necessary, if we cannot diagnose what diseases are present. And the fact that the examination of the lungs takes time is no reason for omitting it.

Also there have been remarks about the impossibility of diagnosing from examination of a few inches of chest. I hope no one ever tried. I examine every case all over the chest and back and have never had the least trouble on the question of taking off the clothing, and have often had parents ask me to examine the child because their own medical man had only examined a few inches. Further, in many cases, I re-examine at the end of a few months. Of the 514 cases which I record this year, 75 have been examined twice, and 17 three times. I have also seen this year 75 of my last year's cases; the majority being examined three or more times. Many of the cases were marked doubtful on the first visit, the diagnosis being made on a second or third examination. Of those actually entered as pulmonary tuberculosis on the first visit I have only seen reason to alter the diagnosis in regard to two.

The results of children examined this year are, briefly, as follows:—

Total examined, 3159. Number with pulmonary tuberculosis, 514.
Percentage with pulmonary tuberculosis, 16·2.

Boys.

Ages 3—6 ..... Number examined, 458; number defective 9·4%
, 12—14 ..... ,, ,, 442; ,, ,, 11·5%

Girls.

Ages 3—6 ..... Number examined, 520; number defective 10·4%
,, 12—14 ..... ,, ,, 1001; ,, ,, 18·7%

The number 3159 includes all children, whether examined for some special reason or in the ordinary routine. But the two age groups given contain practically only routine children, and hence give more reliable results.

There were also 13 boys and 36 girls in whom I could detect no abnormal signs except those of pleurisy. In the Parkes-Weber Prize Essay[7] Dr. W. C. Wilkinson writes: "Pleurisy is merely a phase or form of pulmonary tuberculosis ..... rarely the initial and sole lesion. ..... For years past I have tested with tuberculin every case of pleurisy that has come under my observation ..... and so far in every case tested ..... there has been a positive reaction."

In 8 cases I have entered tuberculosis of thoracic glands—these have been cases in which at least five of Dr. G. F. Still's[8] seven criteria have been present. I have no doubt that this figure is absurdly low, but at present I am not competent to diagnose the condition with certainty.

In addition to the above I have noted 14 cases of bronchiectasis in girls and 3 in boys. In regard to these I am much indebted to an article by Dr. Walter Carr, in which he states that bronchiectasis in children is not

necessarily accompanied by fœtid expectoration. Of my 17 cases the expectoration has only been fœtid in 3. Of course, it is possible that some of these cases are tubercular, and, on the other hand, a few cases entered as pulmonary tuberculosis may in reality be bronchiectasis. But as a rule the distinction is possible, and the history is a great help.

Dr. Riviere states that I "accept bronchitis as evidence of a tubercular process." This is a most inaccurate statement, for which there is no foundation in my paper. Other writers imply that the points I mentioned as "aids to diagnosis," to quote Dr. John Allen,[9] were the only signs and symptoms on which diagnosis was based. In many cases there were plenty of other symptoms of ill-health, but of no diagnostic value. Many of the children were anæmic, but as anæmia is a symptom of a legion of diseases I do not allude to it. Again, in a large proportion of the children the body weight is far too low and the pulse far too variable. But these two symptoms are as often due to other causes as to tuberculosis, and consequently I do not regard them as aids to diagnosis. In regard to the existence of a non-tubercular chronic bronchitis between the ages of five and 50 I would ask any colleague who has experience of post-mortem work to state the proportion between such cases and cases of pulmonary tuberculosis—presuming that microscopic examination be made in each case. I think the proportion will be small. The common history of many cases of fatal pulmonary tuberculosis is recurrent bronchitis every winter for years, then tuberculosis is diagnosed; considering the ubiquity of the tubercle bacillus as shown by the tables given at the beginning of this paper, is it not at least probable that tuberculosis starts early in inflamed bronchial membrane?

An unusually intelligent parent recently asked me to examine her child because she was not gaining strength and they had a tubercular family history. She stated that the child had had two attacks of illness "on the chest" every year for several years, and that these illnesses had been labelled by the several medical men who had attended her as "inflammation of the lungs," "broncho-pneumonia," and "bronchitis," the first two names recurring several times. Now I think that a young child who had had three or four attacks of such serious acute diseases within a short time would not be in the fair state of nutrition in which I found this child. But a chronic lung tuberculosis, with exacerbations two or three times a year, would account for the attacks and the condition. There were slight physical signs in both lungs which agreed with such a diagnosis.

In another case I wrote in March, 1907, that a child had tuberculosis in both lungs. The signs were slight, the condition early. The family medical attendant wrote: "I ..... am very much astonished at Dr. Williams's diagnosis as I feel I cannot agree that the child's condition is as grave as the report infers." The child was excluded from school for some months and improved. But in face of the verdict of the family medical man I do not think that the mother believed in the need for care. Now I regret to say that she has no doubt. In October, 1909, I was asked to examine the child again as she had been more or less ill for some time, and was informed that "the doctor attending her says her lungs are in a bad state." I hope this child may recover, but it will take a long time if she does. Both lungs are considerably affected.

Since writing the above I have read an interesting paper by Dr. J. Allen. I entirely agree with him that due importance should be given to the question of adenoids and, wherever necessary, treatment undertaken. I would, in addition, commend to him one suggestive sentence in the Parkes-Weber prize essay: "Of the cases of adenoids in children all but one reacted" to tuberculin. Many children suffer both from adenoids and pulmonary tuberculosis, and I fear the former often predispose to the latter.

One sentence in Dr. Allen's paper appears to me the crux of the matter: "In *chronic bronchitis* in adults I have been able to demonstrate the presence of bacilli in a few cases, and *these patients were suffering from chronic bronchitis simply*, not from pulmonary tuberculosis as usually understood." (Italics are mine.) In children it is notoriously difficult to get sputum enough for examination, and hence the tubercle bacilli can be rarely found. But if Dr. Allen will admit that they are suffering from the same kind of bronchitis as those of the adults with "chronic bronchitis simply" in whom he found tubercle bacilli I will agree. Only I call this complaint pulmonary tuberculosis.

ENCAPSULATED CEREBRAL ABSCESS,

OF LARGE SIZE AND CONSIDERABLE DURATION, INVOLVING THE TEMPORO-SPHENOIDAL LOBE, ISLAND OF REIL, AND THE VENTRICLES, BUT CAUSING COMPARATIVELY SLIGHT SYMPTOMS.

BY JOHN A. C. MACEWEN, M.B., B.Sc. GLASG., F.R.F.P.S. GLASG.,

SENIOR ASSISTANT TO THE REGIUS PROFESSOR OF SURGERY, GLASGOW UNIVERSITY; ASSISTANT SURGEON, GLASGOW ROYAL INFIRMARY; SURGEON, ELDER HOSPITAL, GOVAN.

History.—A man, 36 years of age, and a miner by occupation, was attended by Dr. J. Alexander of Galston, who asked me to see him in consultation with him at the end of August, and gave me the following history. He first saw the patient in May, when he was suffering from a deep gluteal abscess, which was discharging through an aperture near the anus. The patient made satisfactory progress until June, when the temperature rose to between 102° and 103° F. for a period of ten days, during which the left wrist became swollen and painful. As the condition of the wrist persisted the part was opened up under chloroform and a necrosed carpal bone removed. He again did well until shortly before I saw him, when he developed cerebral symptoms—headache, vomiting, and loss of word memory of an intermittent character.

Examination and symptoms.—The patient was in bed at the time of my visit, but could stand and even walk with a little assistance, and, save for a general weakness, his muscular system revealed no abnormality. Pulse and temperature were both practically normal. While cerebration was slightly delayed, the patient appeared bright, listening to what was said, and answering fairly intelligently. He had frequent difficulty, however, in finding the word he wanted, whereupon he would stop short, shake his head, and give a short laugh, or make several attempts to get the word he wished. Generally he did not accept suggestions of a wrong word. A severe attack of hiccough, from which he had been suffering intermittently during the previous two days, made conversation difficult. The pupils were widely dilated with homatropine, so that pupillary phenomena were obliterated, but optic neuritis was found to exist bilaterally and equally. There was no history nor evidence of nasal nor aural mischief, nor of tubercle or syphilis. There was a suggestion of passivity of the right side of the face, and the tongue on protrusion was slightly deflected to the right.

In view of the history and of the facts elicited I advised his removal to the Royal Infirmary, Glasgow, and he was admitted to that institution under my care, while acting for Mr. P. Paterson, on Sept. 1st. Once the effect of the homatropine passed off, the pupils appeared normal and equal and were recorded as such, but on very critical examination there was a suggestion of sluggishness in the reaction of the left pupil to light. Notwithstanding the slight optic neuritis there was no impairment of vision, and there was no nystagmus, diplopia, or squint. The slight passivity of the right side of the face was again noted, but the condition of both face and of pupil was so slight as to leave one in doubt as to the existence of these phenomena. Both ears contained wax and the postero-superior portions of both drums were slightly inflamed, but there was no perforation. The body generally was well nourished, and, while weaker than normal, no undue weakness of one side as compared with the other could be detected. The knee-jerks were unsatisfactory, the left being very active, whereas the right could not be elicited, although the muscles twitched when the patellar tendon was tapped. There was no ankle clonus. The temperature remained slightly subnormal, while the pulse ranged about 70 and the blood pressure registered

140 millimetres. The patient had repeated attacks of severe hiccough, which lasted for hours at a time and appeared to be provoked by excitement.

The most noticeable feature in the patient's condition, however, was his loss of memory of the names of many persons and things—a form, probably, of amnesia verbalis. Unless a sentence were short and he uttered it spontaneously he generally stuck from want of some word. When questioned this condition became more marked, and if asked to name an article he rarely succeeded in finding the word, even when the object was such a familiar one as his own finger. Generally he would say, "That's —— 'thingamy.'" He appeared, however, to recognise the correct word as a rule when suggested to him. If a friend came in he would say, "Hullo, Mr. Smith, how are you?" quite correctly, but if asked afterwards who had been to see him he would rarely be able to give the name of his visitor, although he appeared to clearly remember the visit and the visitor. He very frequently made mistakes as to the number of his brothers, and this was considered by some as evidence of loss of memory, but I am disposed to think it arose from confusion between brothers who lived at home with him, and others who were in England. He was frequently told the name of the infirmary, the names of the medical men and nurses, and so forth, but during this period he never remembered them, although he would repeat them quite correctly at the moment. The Sister he always referred to as "Jean," which was his wife's name, but I think he did this with the desire to tease, and, indeed, there was constantly noticeable a desire on his part to give "smart" answers, a condition frequently noticed in cerebral affections. That his intelligence and reasoning faculties were fairly sharp was shown repeatedly, as, for example, on one occasion, while examining him, I saw his attention arrested by a man being carried out of the ward on a stretcher, when he immediately asked, "Is that man gaun hame?" and, indeed, he constantly informed us that he was "gaun hame."

He was also reported to be able to read easily, but while I did hear him read small words correctly I was not satisfied as to larger ones, although there was, of course, difficulty in gauging his standard of education. Even with small words he made mistakes, as, for example, on one occasion when he appeared absorbed reading a magazine I asked him what he was reading. He promptly and erroneously answered, "Pearson's," and insisted on the word "New," which was printed on the title-page, being "Pearson's." He also about this time wrote a letter to his wife, which I did not see, but which I was informed began quite intelligibly. He certainly could generally write short words.

For a week subsequent to admission little further was noted. The pupils became slightly more contracted, but remained equal. The temperature remained steadily slightly subnormal—98° or less; the pulse ran between 80 and 90, while the blood pressure tended to rise, reaching 150 mm. On Sept. 5th, when the blood pressure was at its maximum, the patient had several attacks of spontaneous vomiting, but he had no headache at this period.

A note made on Sept. 12th states that the patient had been much better, so much so that some members of the staff thought he might be sent home, but was getting more difficult to manage. He would not take his medicine, would not lie down, and was constantly "goin' hame." When I interviewed him he told me he was fine, was "goin' hame," and got out of bed to let me see how fit he was, walked up and down, and stood with his eyes shut. Amnesia verbalis, however, was more marked than ever, so that it was difficult even to assist him. The following forenoon—Sept. 13th—he became comatose after an attack of hiccough and vomiting, and could not be roused to speak or look. The pupils were equal and contracted. There were slight twitchings of the right arm.

Up to this period, while cerebral pressure was indicated by the low temperature, contracted pupils, and congested discs, it was difficult to determine the site of the lesion. The facial paresis and sluggishness of the left pupil, if really present (and most observers were not inclined to admit their presence), indicated the left temporo-sphenoidal lobe, and this site likewise tallied with recent theories as to the location of a speech centre in the temporo-sphenoidal lobe. I had accordingly determined, if called to act in an emergency, to expose the left temporo-sphenoidal lobe, and the twitchings of the right arm, which now occurred, strengthened my diagnosis.

Operation.—As the patient was not absolutely unconscious and was rather restless a little chloroform was given, and almost immediately the anæsthetist drew my attention to the fact that the left pupil, which had been so long watched in vain for evidence (beyond the slight sluggishness) had dilated widely, while the other remained contracted.

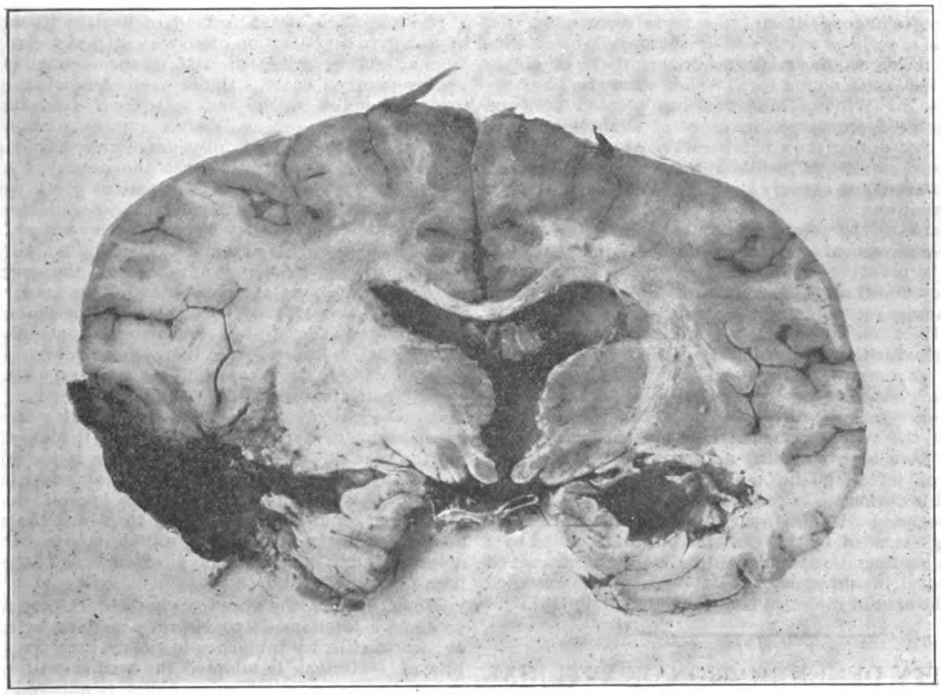
There could now be little doubt as to the localisation of the affection, and the skull was opened as in the mastoid operation, the bone being very thick and the antrum practically obliterated, suggesting old-standing middle-ear disease. The dura mater over the temporo-sphenoidal lobe was exposed and was found tense, with complete absence of cerebral pulsation. On incising the dura mater the brain matter bulged slightly into the wound, while the pulse was reported to become faster and the pupil less dilated. As nothing was detected near the surface of the brain exposed the opening was much enlarged vertically upwards from the antrum, the brain matter now being extruded freely on incising the dura mater. A mass was finally detected lying fully an inch from the surface of very considerable size. An endeavour was made to "tempt" this mass to the surface, but failed, owing possibly, it was thought, to the almost entire absence of brain pulsation. On account of its size, depth, and adhesions, however, it was found to be impossible to shell the mass out. Accordingly, a trocar was introduced into it and over 2 ounces of pus were evacuated, the pupils meanwhile becoming equal and the pulse rapid. A portion of the abscess wall was now caught and an endeavour made to bring it to the surface, but with very indifferent success. The cavity was, therefore, lightly packed with oiled gauze and the surrounding parts shut off with packing. The pus was examined and found to contain staphylococcus pyogenes aureus.

Condition subsequent to operation.—After this operation the patient became so well that hopes were entertained for his ultimate recovery. He was perfectly bright and intelligent; there was no vomiting or headache; he knew where he was; soon knew the names of those around him; could generally name an article when asked to do so; and could read with ease, unless presented with very large words.

On the 25th—12 days after operation—notwithstanding careful and regular dressing, during which the abscess wall had been partly extruded, the headache returned, and he did not recognise relations, and the temperature, which hitherto had remained normal or subnormal, rose to 100°. When dressing him on the 26th a small bag of pus was found protruding from the wound, the thin covering of which resembled the lining membrane of the ventricles. On carefully removing the little bag there was for the first time a considerable flow of cerebro-spinal fluid, which almost certainly came from the descending horn of the lateral ventricle, into which the abscess had projected. On the 27th the headache increased, and there were vomiting and hiccough. On dressing, some remnants of the cyst wall came away, but the patient became comatose with moderately dilated and irresponsive pupils. Respiration became of the Cheyne-Stokes character; the temperature rose to 105°, the pulse became very fast, and death supervened.

Post-mortem examination.—A post-mortem examination of the head was kindly permitted. The skull was opened, and the brain carefully removed, along with a considerable portion of the dura mater over the affected area. A very considerable collection of purulent material was found at the base surrounding the medulla, but a careful examination of the wound showed that the dura mater was firmly adherent all round the opening, and it therefore became a question how this material had reached the base. After hardening, the brain was cut into portions about ½ inch thick by a series of coronal sections and an examination made.

The whole ventricular system was enormously distended. The lateral ventricles began anteriorly vertically above the olfactory bulbs, and were from ½ to ¾ inch in diameter at the commencement, and increased in size as they extended backwards. The descending horns were particularly affected, that on the right side attaining a diameter of 1¼ inches at a point opposite to the lesion on the left side. On the left side the lesion obviously involved the descending horn of the lateral ventricle, which was much smaller than its neighbour, and in places was practically obliterated.



The posterior horns of the lateral ventricles measured 2 inches in their greatest diameter. The third and fourth ventricles were also markedly distended. It is difficult to believe that this distension was purely the result of infection occurring a few days prior to death. It is possible that a simple hydrocephalus had been caused by the pressure of the abscess on the valve of Vieussens and other communications between the ventricles and the extra-ventricular system, pyogenic involvement occurring late in the course of the disease, but the location of the lesion and the condition found post mortem do not favour this view. Cases have occurred in which there was reason to believe that leakage from an abscess had occurred into the ventricles for some very considerable time prior to death, pus containing organisms being thus slowly poured from the abscess into the ventricles, where the organisms would give rise to further mischief. As the organisms in this case were active staphylococci aurei, it would be reasonable to suppose that active destruction would follow their being set free in the ventricles, the patient exhibiting symptoms such as he did a day or so before death. The writer is inclined to attribute the distension to an inflammatory process produced over a prolonged period by the diffusion of toxins, but not of organisms, from the abscess cavity, through the thin lining membrane of the ventricle, which formed the inner wall of the abscess cavity. The products of this inflammatory process, both serous and corpuscular, probably distended the ventricles, but ultimately escaped by the valve of Vieussens, while, as no organisms were present, the process would not spread, the purulent material gradually collecting at the base, where it was found on post-mortem examination.

As the abscess had been evacuated two weeks prior to death, and almost the whole of the containing wall had been removed, the affected parts had collapsed greatly, and thus the precise extent of the original focus was difficult to determine. The area found post mortem to be affected began on the surface anteriorly about one inch behind the Sylvian fissure, involving the superior and middle temporal gyri. In this position it extended about ¾ inch into the brain substance. As it extended backwards the affected area became wider, involving also the inferior temporal gyrus, while it also extended much more deeply into the brain substance, until, at the position of a line joining the supra-marginal gyrus above with the junction of the pons and medulla below, it reached a maximum. Here it extended upwards and inwards for fully 1¾ inches, coming to within ½ inch of the lateral ventricle itself, while a little behind this point it terminated rather abruptly. The descending horn of the lateral ventricle was in places almost entirely obliterated, the affection extending upwards and inwards above it, and affecting and crushing the island of Reil, and possibly to a slight extent the lenticular nucleus. (See figure.)

To summarise, then, the pathological condition. An encapsulated abscess, containing over 2 ounces of pus, was situated about 1 inch below the surface of the upper portion of the temporo-sphenoidal lobe, its inner wall being formed by the lining membrane of the descending horn of the lateral ventricle, into which it projected, while its upper wall encroached upon and crushed the island of Reil and adjacent parts. The whole ventricular system was greatly distended, and its lining membrane much thickened and congested.

Remarks.—In conclusion, one would draw attention, in the first place, to the slight disturbance created by the large abscess, and in particular to the comparative absence of focal symptoms. As stated, both facial paresis and sluggishness of pupil were so slightly marked as to make their presence doubtful even to trained observers, and, apart from the occasional attacks of hiccough and vomiting, the disturbance of speech was the point which was most noticeable. The comparative slightness of the disturbance is presumably to be accounted for by the slow rate of growth of the focus, which permitted the parts to adapt themselves to the increasing pressure, while the gradual distension of the ventricles probably acted as a distributing and equalising agent of the pressure, thus preventing marked focal symptoms. It would also appear probable that as the abscess grew it projected into the descending horn of the lateral ventricle in addition to displacing the surrounding brain matter.

On account of the marked amnesia verbalis it was of the utmost importance to determine the significance of this symptom and particularly its value as a focal symptom. It is not the writer's object to discuss the various theories

Section through area of maximum disturbance, in line of mastoid antrum. Note the dura mater adhering to the margins of the wound: the involvement and practical obliteration of the descending horn of the lateral ventricle (much distended on the other side), and the extension of the process to within a short distance of the lateral ventricle, which is compressed.

regarding the location of speech in the brain, nor would he propose to draw conclusions regarding the matter from the present case, as the large size of the lesion and the wide diffusion of the pressure would render such conclusions unreliable. It is, however, well to note that in this case there was no motor speech disturbance. The patient had no difficulty in speaking so far as the mechanical part of speech went, but he did constantly forget words. From a pathological standpoint there was no evidence of any disturbance of Broca's lobe, the anterior limit of the lesion terminating an inch behind the Sylvian fissure, while from an anatomical and clinical standpoint it is well recognised that, as the frontal lobes rest upon a higher shelf, so to speak, than the temporal, pressure from a temporal lesion is generally directed upwards toward the face centre of the Rolandic area and inwards toward the third nerve and not forwards toward Broca's convolution, at least until the pressure has become quite generalised. On the other hand, the temporal lobe, the island of Reil, and to a less extent the lenticular nucleus—structures included in Marie's quadrilateral—had either been actually invaded by the lesion or crushed by it.

The sudden dilatation of the pupil on the administration of chloroform was probably due to some very slight, but sudden, increase in congestion of the parts surrounding the focus, and it is perhaps worth asking whether slight congestion caused in this manner might not frequently be of use in clearing up the location of a focus which otherwise has been masked. As Sir William Macewen has pointed out, one frequently notes, for example, in cases of slight tubercular meningitis, that during the administration of an anæsthetic the pupils become unequal, while squint may also develop, which phenomena are entirely absent while the child is in its natural condition.

With regard to the treatment of encapsulated cerebral abscess, where removal of the whole focus, intact, is impossible, it is probably generally better not to endeavour to remove the cyst wall after evacuation of the contents. The writer was anxious to minimise the chances of the formation of a septic tract from the surface to the abscess through the brain matter, with the risk of dissemination therefrom, and hence tried to remove the cyst wall by gentle traction repeated on each occasion the wound was dressed, as well as at the operation. In the present case the connexion of the abscess with the ventricles renders it doubtful if the wall would ever have been extruded naturally, but the risk in such cases of infecting the ventricle while removing the abscess wall is obvious. In cases where the cyst is not intimately associated with the ventricle it often comes away intact, being extruded by the cerebral pulsation, aided by a little gentle manipulation; but even such a form, if opened prior to removal, would probably best be left to be extruded naturally, the area of infection being thereby minimised.

THE FATTY DEGENERATION OF ARTERIAL HYPERTENSION.

BY LESLIE THORNE THORNE, M.D., B.S. DURH., M.R.C.S. ENG., L.R.C.P. LOND.,

LATE MEDICAL EXAMINER TO THE LONDON COUNTY COUNCIL TECHNICAL EDUCATION BOARD.

IN the clinical investigation and study of diseases of the heart and circulation it is of the utmost importance to recognise the fact that arterial hypertension, if untreated, is progressive, and will ultimately lead to degeneration of the vessel walls and all the discomforts and dangers of a premature old age. That the process is very slow and may continue to progress for years before any symptoms noticeable to the patient are manifested is an undoubted fact, and it is for this reason that this disease is often well established before its cause is recognised. In its early stages it is practically impossible to diagnose arterial hypertension unless observations of the blood pressure are made, and if this is not done many early symptoms may appear unimportant, and be either disregarded or overlooked.

The two most common forms of tissue degeneration, the result of arterial hypertension, are those of atheromatous degeneration and fatty degeneration accompanied by infiltration. I do not propose to discuss the former in this paper, nor do I wish to attempt to draw any hard-and-fast line of demarcation between fatty degeneration and fatty infiltration, as the two conditions may each be caused by a deoxygenated blood-supply, and are so intimately connected that it is not possible to separate them in clinical investigations. My object is to draw attention to that form of degeneration, the result of arterial hypertension, in which fat is developed in the place of normal healthy tissues, and to outline the leading symptoms together with the methods of treatment which I have found of the utmost value, not only in arresting the degenerative process, but in restoring the patient to health and strength.

Whatever may be the primary cause of hypertension, whether it be originally due to the poison of gout, rheumatism, malaria, influenza, intestinal auto-intoxication, alcoholism, or any other toxæmia, the history and ultimate result will be the same if the condition itself is not treated. The tension in the vessels rises, the heart in attempting to carry on an efficient circulation is overworked, and consequently dilates, the circulation becomes impaired, all the organs are badly supplied with blood of an impure quality, and the whole system suffers from a nutritive degeneration and is rendered less and less capable, as time advances, of throwing off the original poison that started, and tends to steadily increase, the degenerative process.

The formation of fat instead of healthy tissue is a form of nutritive degeneration often met with in patients suffering from arterial hypertension, with its accompanying overloaded and overworked heart. Under these conditions the patient begins to put on weight and to suffer from dyspnœa on any unusual exertion, especially after a meal, when the stomach is dilated; this tends to discourage the taking of exercise and thereby to directly increase the obesity. As fatty degeneration slowly advances the patient gives up, first one, and then another form of exercise, and ultimately is unable to walk more than a short distance with comfort, on account of the dyspnœa arising from a dilated and fatty heart and an increasing bulk. As time advances all the organs become congested, the bowels, stomach, and liver cease to perform their functions perfectly, and the lungs become subject to a chronic catarrhal condition, accompanied by attacks of cardiac asthma, which cause great distress and prevent the patient from sleeping in the recumbent position, and palpitation and cardiac pains follow on any exertion.

It takes many years for the patient suffering from the fatty degeneration of hypertension to get into the above condition, but the very slowness and insidiousness of its advance is a danger, as the patient who is usually approaching, or past, middle age gradually accommodates himself or herself to the altered conditions, and begins to regard them more as a necessary accompaniment of advancing years than as a disease which can be first alleviated and then kept in hceck by suitable treatment.

When, in time, the symptoms become irksome and painful, an effort is often made to improve matters by a rigid diet, or, worse still, by inulgence in violent exercise. If the first line of treatment is adopted the weight will probably be reduced whilst a strict rule of diet is adhered to, but the health will be rendered worse rather than improved, as this class of patient does not possess the physical stamina necessary to withstand either an entire alteration in diet or a modified starvation. If the second line of treatment is adopted the heart's action is further impaired and the severity of the symptoms is increased, with often a fatal result.

In a typical case of fatty degeneration due to arterial hypertension the patient is overfat, with often a high colour, has a high arterial tension, but no signs of atheromatous degeneration of the blood-vessels, cold extremities, a urine of low specific gravity, showing a deficiency of the solid constituents, but no albumin, an increased cardiac dulness, very feeble cardiac sounds, and sometimes œdema of the legs and feet. These cases may be mistaken for ones of chronic nephritis, but are distinguished from them by the fact that the impulse at the apex is often absent, or very slight, and that the heart-sounds are only feebly heard at the apex, and are often too feeble to be audible over the aortic and pulmonary areas. This condition, combined with an increased cardiac dulness, indicates a dilated and fatty heart, in contradistinction to the hypertrophied and over-vigorous heart of chronic nephritis. The most important difference between these cases and those of chronic nephritis is demonstrated by the fact that, with suitable treatment and care, the former can be restored to good health, the arterial tension lowered, the cardiac dilatation cured, the fatty degeneration arrested,

and the weight greatly reduced, without resort to any strictly limited dietary or drugs of the vaso-dilator group.

Treatment.—The objects to be aimed at in the treatment of these cases are, firstly, to lower the blood-pressure without weakening the patient, thereby resting the heart and setting up a more healthy condition of the circulation; and, secondly, to reduce the weight, so that the heart has a less arduous task to perform, and is not impeded by a superabundance of fat.

There is no treatment which lowers high arterial tension in so satisfactory a manner, and is less likely to weaken the patient and derange the body functions, than the administration of a graduated course of baths prepared artificially so as to resemble in all active ingredients the natural waters of Nauheim. In conjunction with these baths regulated resistance exercises should be given, the patient should be ordered a definite amount of gentle walking exercise, and a diet in which food rich in carbohydrates is given sparingly.

Patients will continue to improve in health for months after such a course of treatment, the various organs of the body gradually resuming their normal conditions and carrying out their functions in an increasingly satisfactory manner. The weight also, which may only fall a few pounds during the course, will continue to diminish for a long time. The reason for this continued improvement over a period of several months is due, I believe, to the gradual repair of nutrition taking place in degenerate organs long accustomed to a defective and impure blood-supply.

The administration of drugs in these cases has been proved to be highly unsatisfactory, for if those belonging to the digitalis group are used the arterial tension is further raised, and although the patient may feel benefited for a time, the stimulating effect of the drug will soon wear off and the case will be left in a worse condition than before the treatment; the above procedure may well be likened to the whipping-up of a tired horse. If, on the other hand, drugs of the vaso-dilator group are given, the blood-pressure is possibly lowered for the time being, but at the cost of lowering the vitality of the patient to a marked degree, as such drugs, whilst lowering the blood-pressure, act also as depressants upon the heart.

There are no such drawbacks in connexion with the treatment by baths and graduated exercises, as by this method of treatment the blood-pressure is *lowered*, but the cardiac action is *not depressed*, and therefore the heart has less strain put upon it and less work to do, and consequently can recover tone and contractility, whilst at the same time it is supplying itself with an increasingly pure and satisfactory blood-supply; hence, instead of a vicious circle, consisting of a steadily weakening heart, giving an increasingly poor blood-supply, not only to the organs of the body but to itself also, we get a better nutrition, and consequently a more perfect action of this organ, the function of which is to carry on the nutrition both of itself and of the whole system.

Queen Anne-street, W.

LITERARY INTELLIGENCE.—Messrs. Baillière, Tindall, and Cox announce the following for publication during the next few days:—An English translation of Professor Dieulafoy's well-known text-book of medicine ("Pathologie Interne"), by Dr. V. E. Collins and Dr. J. A. Liebman; "Diseases of the Ear," by Dr. A. A. Gray, containing numerous original illustrations, many of which are stereoscopic; an eighth edition of Sir William Whitla's "Pharmacy, Materia Medica, and Therapeutics"; "An Introduction to the Study of Hypnotism," by Dr. Hugh Wingfield; and "Nursery Hygiene," by Mr. M. Feldman. In addition to the above, the same firm hope to publish during June several other important works, including "Accidents in their Medico-legal Aspects," by Douglas Knocker, which will be an exhaustive work on the new Employers' Liability Act; "Medical Inspection of School Children," by Dr. E. M. Steven—the result of his investigations in this country, Canada, Germany, and the United States as Commissioner for Australia; "Syphilis and its Treatment," by Colonel F. J. Lambkin, R.A.M.C.; and a second edition of "Military Hygiene," by Colonel R. Caldwell, R.A.M.C.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Cases.

A MEETING of this section was held on May 27th, Dr. J. WALTER CARR being in the chair.

Dr. F. PARKES WEBER showed a case of Ateliosis in a man aged 42 years. The patient is an infantile dwarf, whose physical development roughly corresponds to that of a boy aged 9 years, but his expression, the wrinkles on his face, his attitude, his manner of speaking, and his general behaviour are those of an adult. He was born in 1868, and it is said that his development was normal up to the age of 9 years, but that it then ceased. The shape of his trunk, the undeveloped state of his sexual organs, the absence of any "pomum Adami," and the high pitch of his voice are those of a child. There is no hair upon his face or pubes. Mentally he seems normal. Skiagrams of the extremities show persistence of some of the epiphyseal cartilages, but the amount of union with the diaphyses varies considerably in different bones. There is no history of any similar condition in the family.

Dr. CARR showed a case of (?) Myositis Fibrosa. The patient was a girl aged 4½ years; there are three other children in the family, all healthy. The child began to walk when 16 months old, but six months later she was unable to walk or stand. Two years ago her arms became weak. At present the child cannot fully extend either the hips or the knees; there is no limitation of flexion, but abduction of the hips is much restricted. The left arm cannot be completely supinated. There is no pain on movement. There is no rigidity of the muscles. The mental condition is normal. Skiagrams show no definite evidence of bone disease nor any ossification of the muscles.—In discussing the case Dr. EDMUND CAUTLEY doubted the condition being one of myositis fibrosa, and thought it analogous to the contracture of limbs which one saw in prolonged toxæmic conditions where the patients were confined to bed.—Mr. J. P. LOCKHART MUMMERY took a similar view of the case and advised treatment by means of weight extension over a prolonged period.

Dr. G. BELLINGHAM SMITH showed a case of Amaurotic Family Idiocy. The patient, a female aged 11 months, was taken to the hospital for blindness and inability to sit or hold her head up. The symptoms had only been noted for one month. The child is exceedingly fat, but the general condition is one of extreme apathy; no movements of the head or body are attempted, and those of the limbs are limited. Further examination of the limbs reveals a variable degree of rigidity. An ophthalmoscopic examination reveals changes characteristic of the condition. These changes are bilateral and consist of marked pallor of the optic discs, while in the yellow spot region there is a greyish-white area surrounding a bright pink spot.

Dr. T. R. C. WHIPHAM showed two cases of Congenital Malformation of the Heart. The first case was a child aged 1 year 9 months. Cyanosis was first seen when he was a fortnight old and has persisted. It is very marked on the face, the extremities are deeply congested, and all the digits are clubbed. The heart is enlarged. At times there is no murmur, while at others a soft systolic bruit is audible in the pulmonary area. The child also has congenital ptosis of both eyelids. The second case was a girl, aged 18 years, with congenital pulmonary stenosis. She has always been cyanosed and suffered from shortness of breath, but has had no other cardiac symptoms. She presents a typical blue appearance and clubbing of the digits. The heart is enlarged and there is a typical rough systolic murmur.—The cases were discussed by Dr. CARR, Dr. FRANCIS H. HAWKINS (who quoted a similar case of his own kept under observation until 21 years of age, and another case which had reached adult life), Dr. PARKES WEBER, and Dr. CAUTLEY.

Dr. WHIPHAM also showed a case of Air Swallowing in a boy aged 12 years. There was a habit of continuous forced eructations. The abdomen was not enlarged. The patient had suffered from a similar condition two years previously.

Dr. HILDRED B. CARLYLL exhibited a Sarcomatous Tumour from a child aged 2 years. The specimen was removed from a girl who was admitted to the hospital suffering from distension of the abdomen, which had been noticed six weeks prior to admission. Abdominal exploration gave a negative result and exploratory laparotomy was performed. The tumour was discovered which appeared irremoveable, and the abdomen was closed. The child died a week after admission. At the post-mortem examination the tumour, which weighed 6½ pounds, was found to be attached only by a few adhesions to the bladder, and by a branch of the left common iliac artery, and a thin peritoneal covering. Microscopically, it was a myxosarcoma.

Dr. WHIPHAM communicated the pathological report on the case of Myelogenous Leukæmia in an infant, aged 18 months, shown at a meeting of the society on Feb. 25th last.

Dr. HAWKINS read a paper on a case of Malignant Endocarditis of the Tricuspid Valve in a child aged 6 years.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.

A MEETING of this society was held on May 25th, Dr. BYROM BRAMWELL, the President, being in the chair.

Dr. J. S. FRASER exhibited: 1. A woman who had suffered from Chronic Suppurative Otitis Media complicated by septic thrombosis of the jugular bulb and of the internal jugular vein. After operation the patient made a good recovery and had regained almost a normal degree of hearing in the affected ear.

Dr. DAWSON TURNER showed: 1. A woman suffering from Rodent Ulcer at the Left Angle of the Mouth and Nose. She had been treated by the X rays, and on two occasions the ulcer had been scraped, but neither these nor other forms of treatment had benefited her. Treatment by radium for 57 milligramme hours had greatly improved her condition, and at present there were numerous impetiginous crusts which were often exhibited by patients undergoing cure by radium. 2. Three cases of Nævus treated by radium. 3. A case of Enlarged Cervical Glands treated by radium and the X rays.

Dr. R. CRANSTON LOW showed on behalf of Dr. NORMAN WALKER: 1. A case of Generalised Lupus Erythematosus in an elderly woman. During her stay in the ward she improved while under quinine for three months, but after discharge her condition relapsed. 2. Several cases of "Port-wine" Nævus under treatment by carbonic acid snow.

Dr. GEORGE MACKAY exhibited a young boy suffering from "Spring Catarrh" of the Eyelids. This was a form of blepharitis with granulations of a pavement-like type on the palpebral conjunctivæ. The case was sent in as one of trachoma, but on healing no cicatrices remain, and the disease is not communicable. It does not lead to destruction of vision as happens in trachoma. The case was being treated by radium.

Dr. G. LOVELL GULLAND showed two cases of Leukæmia in women.

Dr. R. W. PHILIP showed a girl who was undergoing the new treatment for Diabetes Mellitus by massive saline doses, and with a remarkably good result. Three months ago she was excreting 35 grains of sugar per ounce, and passing from 120 to 130 ounces of urine per diem; along with this there was marked acidosis, acetone and diacetic acid were present, and she showed a serious degree of intoxication. Ordinary treatment had little or no effect. On April 7th a massive saline draught was given in the shape of an entire bottle of Hunyadi Janos swallowed in one hour. No urgent diarrhœa followed, and the subsequent day she was allowed only one pint of milk well diluted. This treatment had been repeated at intervals, and as a result the sugar excreted fell to 5 grains per ounce, and then to *nil*, and at the same time the acidosis disappeared. The girl has gained 13 pounds in weight since the commencement of this treatment.

Dr. ALEXANDER BRUCE showed: 1. A case of Bilateral Paralysis of the Spinal Accessory Nerves probably due to division of the nerves during the operation of removing tuberculous cervical glands on either side. The case resembled one of primary muscular dystrophy. 2. A case of Chronic Internal Hydrocephalus. The patient, a girl, aged 13 years, suffered from cerebro-spinal meningitis in August, 1909. On recovery she suffered from recurring headache, optic neuritis, loss of abdominal but exaggeration of other reflexes. The size of the head has gradually increased and the sutures have commenced to separate. The lateral ventricles have been aspirated and a large quantity of fluid has been withdrawn without perceptible benefit.

The PRESIDENT showed a man whom two years ago he had demonstrated as a case of Intermittent Claudication. Subsequently the patient had experienced great pain in the right limb with absence of pulsation from Poupart's ligament downwards, and Mr. C. W. Cathcart had amputated the right leg below the knee on account of gangrene. The condition was due to insufficient blood-supply to the muscles, and a degree of gangrene was commencing in the toes of the left foot. The patient has become very cyanotic and breathless owing to cardiac failure. His red cells amount to 8,000,000.

Professor F. M. CAIRD exhibited: 1. A patient after removal of 277 Chondromata from the Right Hip-joint. 2. A man after Removal of the Entire Scapula for Sarcoma. The patient lost hardly any blood, and the deltoid was stitched to the trapezius so that a fair degree of movement was obtained. 3. Ten men on whom Professor Caird had performed Removal of Half the Tongue and Glands for Epithelioma within one year. They all exhibited remarkable freedom of speech and power of swallowing. All the operations were performed under local anæsthesia induced by cocaine and adrenalin. Two men were shown on whom the same operation was performed two years ago, and other two from whom the half tongue was excised three years ago. 4. A lad after Appendicostomy for Colitis.

Mr. J. M. COTTERILL showed: 1. A case of Arterio-venous Aneurysm which involved the facial and ophthalmic vessels, and which was cured by ligature of the common carotid artery. The patient fell out of a dog-cart in July, 1905, and after remaining unconscious for eight hours experienced a loud noise in his head, and four days after the accident noticed a projection of his right eyeball. On examination in June, 1907, diplopia was present, and a large vascular tumour was present in the right eye; the ophthalmic vessels and the angular branches of the facial were involved on both sides. 2. A case of Subtemporal Decompression of the Brain for suspected Tumour. The patient was a man, aged 64 years, and in October, 1909, suffered from optic neuritis, headaches (not severe), gait unsteady, and great mental disturbance. No localising signs were present. A piece of bone as large as the palm of the hand was removed and the tissues were then replaced. This allowed the brain to expand and a large swelling now presents in the subtemporal region. The patient has improved remarkably; his memory has returned and he walks well. 3. A case of Occipital Decompression with great improvement. A large piece of bone was removed from the occipital region as far down as the foramen magnum. Von Pirquet's reaction was markedly positive and there was a strong family tuberculous history. In December, 1909, the lad suffered from headache, dizziness with sudden blindness, vomiting, loss of weight, with great mental disturbance. After two operations he became much worse and appeared moribund, when one ounce of cerebro-spinal fluid was withdrawn on two occasions from the cerebellar protrusion, and at once improvement commenced.

Professor H. ALEXIS THOMSON showed: 1. A patient in whom, after Demonstration of a Calculus in the Ureter by the X Rays, it was removed by transperitoneal ureterotomy. 2. A series of patients After Facio-hypoglossal Anastomosis for Facial Paralysis to show the power of movement which was regained. 3. A patient after Complete Extirpation of a Large Pancreatic Cyst.

Mr. CHARLES W. CATHCART exhibited: 1. A patient who illustrated the Effects of Irritation Confined to the Mucous Membrane of the Vermiform Appendix. The lad suffered such severe pain in the back as to cause him to stop working. The symptoms were not typical of appendicitis and no renal symptoms were present. On removing the appendix it was found to contain a few coiled hairs and two fragments of bone or shell. The mucous lining was deeply congested and irritated and a few drops of pus were present, though nothing abnormal could be detected on the exterior aspect. After operation all the symptoms disappeared. 2. A boy, aged 6 years, who had suffered from Fæcal Fistula for a year as a result of a gangrenous intussusception. 3. A case of recovery after very severe cut-throat; the tissues had been

divided down to the vertebral column above the level of the hyoid bone.

Mr. J. W. STRUTHERS showed for Mr. J. W. B. HODSDON a man, aged 29 years, after removal of Spindle-celled Sarcoma from the brain two and a half years ago. The headache and other symptoms soon disappeared and though the man is blind he is in other respects in good health.

Mr. DAVID WALLACE exhibited: 1. A patient after Excision of the Cæcum for Carcinoma. The symptoms commenced in July, 1909, but an absolute diagnosis was not made until six weeks ago. 2. A girl, aged 5½ years, after Nephrectomy for very large Sarcoma which probably grew from the right suprarenal gland. The operation was done by the transperitoneal route on May 6th, and though the kidney was not involved it was completely flattened. The child has made an excellent recovery and has a ravenous appetite.

Mr. ALEXANDER MILES showed: 1. A boy, aged 10 years, after operation for Acute Osteomyelitis of the Spine. Sixteen days before admission he was perfectly well, but was suddenly seized with very severe pain on the left side of the back, and a few days later a large swelling appeared on the left side of the dorso-lumbar region. On opening this pus and fragments of the transverse processes of the vertebræ escaped. The boy has made a good recovery. 2. A man on whom Cardiac Massage was successfully performed for cardiac arrest during operation. The operation was one of gastro-enterostomy for duodenal ulcer, and all went well until the closure of the abdominal wall, when he suddenly to all appearance died. Mr. Miles ripped open the abdominal wound and compressed the heart from within as well as from without, and ultimately cardiac action was restored.

Mr. GEORGE L. CHIENE showed: 1. A young woman, aged 26 years, recently operated on for Acute Gall-stone Colic. This was an early age for this to occur at. 2. A man, aged 52 years, with Osteomyelitis of the Femur and a Peculiar Condition of the Right Patellar Tendon. The osteomyelitis had commenced 40 years ago.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Bovine Piroplasmosis.—Exhibition of Specimens.

A MEETING of this section was held on March 4th, Dr. A. H. BENSON, the President, being in the chair.

Professor METTAM read a paper on Piroplasmosis and Experimental Piroplasmosis. The paper was followed by a discussion, in which Professor W. H. THOMPSON, Professor A. C. O'SULLIVAN, Dr. P. J. O'FARRELL, Dr. ALFRED R. PARSONS, and the PRESIDENT took part.

Professor METTAM, replying to the various points raised in the discussion, said that bovine hæmoglobinuria was very common throughout the whole of Ireland. On one farm, where new cattle were introduced from Scotland, 48 out of 59 got red-water, and 8 or 9 of the number died. He was convinced that there was more than one form of piroplasmosis in Ireland. He had seen cases from County Clare, where there was piroplasma bigeminum, but in other parts—from Cork to Antrim—cases were due to much smaller parasites, one which was bigeminate, but in the most part circular or spherical. This was the one which he had failed to reproduce, and further experiments were necessary to show whether it was inoculable or not. In "Dum-dum" fever he thought that the micro-organism was not a piroplasm, but one more nearly related to the flagellates. As to leucocytosis, he thought that there was, if anything, a leucopenia, and apparently nothing like phagocytosis occurred. The white corpuscles certainly did not attack the parasites. The term piroplasma bigeminum was used generally rather than specifically. It was the parasite which caused Texas fever, and tick fever in Australia, and South African red-water, so-called. But quite a host of piroplasmata had been demonstrated in Assam, China, Japan, and in Transcaucasia, where they were of the bacillary nature, probably resembling somewhat the piroplasma mutans. He was convinced that the parasite met with most commonly in Ireland, and called bigeminum, was quite a special one. The disease was not very fatal in Ireland, the mortality being probably not more than 5 per cent. A carcass of an animal suffering from the disease would not come into the market, as the spleen was very large and the dresser would take it to be anthrax and would get rid of the carcass. In cases of canine piroplasmosis, many dogs had been saved by trypan blue. Animals injected with it became blue, but the colour passed off in a short time.

Mr. WILLIAM TAYLOR exhibited a specimen of Hypernephroma removed from a man 50 years of age. He said that he first saw the patient in September, 1909, when a history of an attack of pneumonia in October or November of 1908 was given. During the interval he had been expectorating quantities of pus every day, with occasional periods of two or three days without expectoration, the expectoration following a pain in his side. The patient had also noticed a swelling in the upper part of his abdomen on the right side. Externally a tumour was obvious, extending below the navel to the right iliac fossa. It was hard, but tender on deep pressure, and moved with respiration. Mr. TAYLOR thought the condition either an abscess in the liver, which was being evacuated through the lung, or a hypophrenic abscess displacing the liver. On opening the abdomen through the right rectus muscle he found the liver practically normal. The right lobe was smaller than normal, but it was pushed up, and with it the diaphragm. Then they saw the enormous mass in the kidney, whereupon he turned the patient round and evacuated a considerable quantity of pus with some blood and necrotic tissue. For a couple of days the patient expectorated blood, but this gradually ceased. There was no trace of pus in the sputum after the first ten days. The patient went out and attended to his affairs before they attempted removal of the tumour. Careful inquiry elicited the fact that 18 years ago he passed blood without any apparent cause. During the subsequent three years he had on five or six occasions noticed blood in his urine, but it passed off. About a month ago he was again admitted to hospital in fairly good condition, but with fœtid pus freely discharging from the wound. Mr. Taylor reopened the abdomen and removed the growth, which weighed 6 pounds. The patient has since left the hospital apparently quite well.—Dr. W. BOXWELL said that sections showed that it was an epithelial growth. Some parts were solid epithelium and some were tubular. It was exceedingly vascular, and seemed to be a typical hypernephroma. It was uncertain whether the tumour should be looked on as an adrenal rest or not. Sections of the kidney showed nothing remarkable. Any changes were simply due to the pressure of the tumour and atrophy resulting therefrom.

Dr. BOXWELL showed a specimen of Abscess of the Heart, removed from a man aged 45 years, who had been found leaning against the railings of the hospital and was admitted in a fainting condition. His temperature was 100° F., and his pulse-rate between 180 and 200. He had a bad alcoholic history, but denied syphilis. Large hypodermic doses of strychnine and digitalin to steady the heart had no effect whatever. He became rapidly weaker and died next day. At the post-mortem examination an abscess was found in the posterior wall of the left ventricle, discharging pus into the cavity. Dr. Boxwell surmised that there was probably in the first instance a gumma of the heart wall, which had become secondarily infected. A large cirrhotic and nutmeg liver was also found, and a large spleen closely adherent to the diaphragm. There was a small basic pneumonia of the left lung.

OXFORD MEDICAL SOCIETY.—A meeting of this society was held in Littlemore Asylum on May 27th, Dr. J. Neil, the President, being in the chair.—Mr. T. S. Good showed three cases of General Paralysis of the Insane in Women, aged 36, 36, and 35 years respectively. None of the patients had any grandiose ideas and they all belonged to the demented type. Two of the patients had increased knee-jerks; in one patient they were absent.—Mr. R. A. Greenwood Penny demonstrated two Cretins, aged respectively 19 and 41 years. The first was extremely demented, deaf and dumb, and showed a very marked cretinous condition which with thyroid treatment for two months had begun to yield, and the mental condition to improve. The second case was in a condition of mild dementia with delusions. This case also was improving on thyroid treatment.—Dr. W. Woolfe Read showed a patient recently in the Radcliffe Infirmary where he was admitted for severe mental symptoms, extensive muscular weakness, and some sensory disturbance. On admission to Littlemore Asylum he had dementia, some delusions of

grandeur, absolute inability to walk, and marked incoördination of all movements. The condition at the present time was one of general paralysis of the insane of the ataxic type.—Mr. Good read a paper on Alcoholic Insanity. In speaking of causation he mentioned the discrepancy between the statistics given by various authorities, which varied from 41·3 per cent. (Clouston) to 3 per cent. (Turner). This was probably due to the attitude of the observer towards alcohol and possibly to local peculiarities. The hereditarily weakened person was more prone to alcohol than another; the quality of the alcohol drunk by large sections of the community at the present time might be inferior to that drunk in earlier times. Alcoholic insanity occurred between 25 and 30 and 35 and 40 years, the period, in the first case, of necessity for a stimulus and, in the second case, of the beginning of mental deterioration in certain individuals. Gastric disturbance and carious teeth were factors among the poorer classes, and habit, especially in rural districts, was probably an important factor. As regarded symptoms, the aspect and the tendency to steppage or waddling gait were mentioned; reflexes were exaggerated or diminished. The pupils showed no constant change. Muscular tremor was always present and sometimes marked. Owing to neuritic disturbances anæsthesia and hyperæsthesia were nearly always present. Amongst mental symptoms the will, judgment, consciousness, and memory were weakened. Impulsive acts, often homicidal, were most dangerous symptoms. Hallucinations were common, nearly always of a terrifying or disgusting nature, and to be accounted for probably from neuritic disturbances in various organs. Delusions were similarly of an unpleasant character to the patient. Epileptic attacks were frequently seen in the chronic alcoholic. Mr. Good divided alcoholism into the following types: 1. Acute: delirium tremens, mania *a potû*, and melancholia. 2. Chronic: delusional insanity, Korsakow's disease, and dipsomania. Each of these forms was illustrated by examples taken from the case-books and the inmates of the asylum. In speaking of diagnosis, the distinctive features of this type of insanity were distinguished from ordinary mania and melancholia, from general paralysis of the insane, epilepsy, and paranoia. The prognosis was always grave, and the treatment could only be successful if undertaken in some institution where the patient could be protected from allowing his vice to be an injury to himself. As regarded medicinal treatment, Mr. Good emphasised the value of capsicum and nux vomica for the digestive symptoms, and hyoscine for maniacal symptoms or great excitability.

Reviews and Notices of Books.

The Conquest of Consumption: An Economic Study. By ARTHUR LATHAM, M.D., and CHARLES H. GARLAND. London: T. Fisher Unwin. 1910. Pp. 185. Price 4*s.* 6*d.* net.

THIS is a book of importance, though its style and method are unpretentious. It is of importance because it suggests a line of conduct in Statecraft, drawn by men who know both the scientific and the economic side of a very important subject; and the volume gains in importance from its modest form, its low price, and its freedom from technicalities, for these very qualities will make it widely read by the thinking laity.

Economists and social reformers are apt to accuse the medical profession of inactivity in the prevention of disease; they forget that the impulses which have produced in Great Britain sanitary conditions which, despite their shortcomings, are unrivalled in the world, originated in the teachings of medicine. The necessity for pure water, good drainage, and ample light and air was originally urged by medical pioneers, and too frequently engineers and amateur administrators are given all the credit for carrying out the suggestions. The question is constantly on the lips of the public, Why is not consumption cured? This volume aims at being a concise answer. The authors hold that the bulk of the scientific work necessary to eradicate tuberculosis from the population is already accomplished: if statesmen could be induced to array and combine the forces at their command to construct a proper organisation and incur the proper expenditure of money the happy result would follow.

"Compulsory notification of tuberculosis is imperative if we are to make real progress." With this many will be in accord; and notification may be impending, though it is not yet enforced. The toll of lives is enormous, despite recent improvements, and it is in this direction that many of our advanced sanitarians are looking. There are about 40,000 deaths from pulmonary tuberculosis alone in England and Wales each year; the authors calculate from this a number of consumptives which approaches a quarter of a million. It is further estimated that there are 100,000 cripples in the country, of whom the bulk owe their infirmity to tuberculosis of joints. Over 18,000 deaths occur annually from non-pulmonary forms of tuberculosis. The figures are sufficient, and are the more striking when we remember that the affected persons are of the most effective working ages, from youth to middle life.

The authors speculate upon the inadequate attention which statesmen have paid to tuberculosis, and suggest that administrators have either never grasped the magnitude of the evil or the amazing advance which has been made in the scientific knowledge of the question. Perhaps the real truth is that Government officials have not sufficient courage to grapple with the problem. The simple methods which sufficed to abolish hydrophobia in England damaged the reputation of a courageous Minister and almost shook the prestige of the Cabinet; the question of vaccination is a hardy annual in the political garden; politicians in England are afraid to deal with widespread evils lest they run counter to the prejudices of ill-informed voters. The proletariat must be educated in the matter, and it is beginning to learn. That it is beginning to learn is evident from the account given in the chapter on "Working-class Organisation," which surveys the work of the National Association for the Establishment and Maintenance of Sanatoria for Workers Suffering from Tuberculosis. This association is a combination of friendly societies and trade unions, and the fact that such a combination should be formed is a lesson to State and municipal administrators. The societies or collegia (to adopt the Roman phrase) who have combined are not philanthropic bodies but insurance societies, and the authors are careful to point out that all schemes devised by these societies are necessarily drawn up on a purely economic basis; their antituberculosis machinery is set up to lower the demands made upon their funds by sickness and death of members, and especially by the long drain of chronic sickness. Largely through the energies of Mr. Garland himself, the employees of the Post Office have established a notable scheme by which they have been enabled to provide sufficient beds and accommodation in sanatoriums, to pay all travelling expenses and to render other assistance in hard cash, and to publish literature of warning and advice—and all this from a contribution for the purpose of 2*s.* a year.

The statistics of mere monetary loss caused by tuberculosis among the wage-earning classes given in this volume are simple but convincing. There is nothing sensational about them and they are largely based on the estimates of the friendly societies. It can be safely affirmed that consumption alone costs the friendly societies £1,000,000 a year in sick benefits. Those familar with the working of the Poor-law estimate that 10 per cent. of the total expenditure of the Poor-law authorities is chargeable to tuberculosis, which sum is roughly £1,500,000 per annum. The annual cost already undertaken by charitable institutions for the relief of consumptives, making allowance for the interest on capital

invested in building and equipment, is little short of £500,000 a year. There appear to be only about 4000 beds in charitable institutions which are devoted to the treatment of consumption in its various stages, so that it may be fairly claimed that no solid attempt is being made on any wide scale to effect cure of individual cases. If to the actual direct expenditure incurred by friendly societies, Poor-law relief, and contributions to charitable institutions (which combined amounts, as we have seen, to £3,000,000 a year) we add an estimated, and quite moderate, loss of wage-earning power and reduction of life capital, we find in the latter two items an additional £4,000,000 a year, making a combined total of £7,000,000.

The authors propound an organised scheme for dealing with the evil; this includes the maintenance of 56,000 persons in sanatoriums for six months, with an allowance to the dependents of patients at £1 per week. The capital expenditure estimated is £3,375,000 and the annual direct expenditure (including interest on capital) is £3,838,000. When we consider that the proposed scheme offers the prospect not only of arrest in a certain proportion of individual cases, but also the further prospect of a considerable diminution in the total of tuberculous inhabitants of these islands, it is manifest that every thinking person must give the proposals submitted his very careful consideration.

Allgemeine Biologie. Von OSCAR HERTWIG, Direktor des Anatomisch-Biologischen Instituts der Universität, Berlin. Dritte Auflage. Mit 435 teils farbigen Abbildungen. Jena: Gustav Fischer. 1909. Pp. 728. Price: Paper, M.16; bound, M.18.50.

PUBLISHED first in 1892 under a different title, this standard treatise now enters on its third edition. The name of Oscar Hertwig is a guarantee of the thoroughness and completeness of the work, though the author, in his modest way, confesses that there are still many lacunæ which he has not filled, and that, viewed from the standpoint of a work on "General Biology," the several subjects are unequally treated. In a work of such compendious dimensions it must be so. Several new chapters have been added, especially on such subjects as the elementary structure of the cell and egg, division and maturation of the ovum, natural and artificial parthenogenesis, hybridisation, transplantation, and on what the author calls the "biogenic law." Entirely new sections are added on grafting and on Mendel's law. Thus the volume is increased by about 80 pages, while the woodcuts, excellent in themselves—a few are coloured—have been increased by 64.

The work is primarily divided into two main parts. Part I., consisting of 416 pages, deals with the cell as an independent organism; Part II. completes the work and deals with the cell in connexion with other cells. Part I. is composed of 13 chapters which deal with the cell first historically and then with its chemico-physical and morphological characters and its vital phenomena. Then the nucleus is fully discussed, together with the interrelations between protoplasm, nucleus, and cell products. The remaining chapters deal with, amongst other subjects, the phenomena and cause of fertilisation and the physiology of the process. The last chapter treats of the cell as the "anlage" of an organism.

Apart from the morphological problems related to protoplasm one of the most interesting, of course, is still amœboid movement. The author does not agree with those observers who regard all the so-called vital movements of protoplasm as in the last instance due to chemical, physical, or mechanical causes. The theories of Berthold upon variations of surface tension, those of Verworn, and others are criticised and rejected as unsatisfactory. The fourth chapter, on the metabolism of the cell, is very interesting, for it deals not only with animal cells but also with vegetable cells and their formative activities. The chlorophyll function is fully discussed and so is the formation of starch. The author takes a wide sweep in this chapter, for not only are spermatozoa and ova discussed, but we have a careful study of "a very artistically formed inner plasma-product"—viz., the "stinging cells" of the cœlenterates—and it is an easy transition to fibrillar formations in these cells, to muscle fibres, or myofibrils.

The fifth chapter is devoted to the motor phenomena manifested by cells. This chapter runs much on the lines laid down by Engelmann. When it comes to the explanation of these phenomena the author will not follow any of the views derived from a study of the phenomena of surface tension, as in the experiments of Quincke, Bütschli, and Berthold, whilst admitting the high scientific interest of these physical experiments on surface tension. A very full account is given of the movements of flagella and cilia. A single paramœcium aurelia has at least 2500 cilia, whilst balantidium elongatum, an infusorial parasite of the frog, has 10,000 of these motor organs, all duly coördinated in their action. Some of the illustrations of ciliary structure are very good. In this chapter we miss the work of Jennings on the "Behaviour of Animals," more especially his careful work on Paramœcium. It may, however, be referred to elsewhere, though we have failed to find it. Jennings's work on these unicellular organisms is of the highest importance. But, after all, according to the author, "the most wonderful property of protoplasm is its excitability or irritability," and this theme he proceeds to develop until he ends by drawing a sharp distinction between machines and organisms. Then follows a study of the various forms of stimuli—thermal, optical (phototaxis), electrical (galvanotropism), mechanical and chemical (chemotaxis).

Naturally, the phenomena of cell division, mitosis, and all allied phenomena in the egg are dealt with in a thorough, fundamental, and exhaustive manner, and this section is particularly well illustrated by means of woodcuts. Then follows an elaborate account of changes produced in the course of division of the ovum by experimental means, such as the influence of gravity or of compression on division of the cell. The cell, as a whole, and the inter-relation of its several parts are then considered; the relation of the nucleus to formative and nutritive processes in cells as studied by Haberlandt in plants forms the introduction to similar studies in animal cells. About 100 pages are devoted to the phenomena, causes, and physiology of fertilisation of the ovum, and again vegetable physiology comes in for consideration, which brings out the identity of the problem in the two kingdoms. The experiments of Loeb on artificial parthenogenesis and his theory of catalysis are cited and criticised—the theory unfavourably. As a matter of fact, artificial parthenogenesis can be induced in many different ways. It is the interpretation of the phenomenon which is the difficulty, and when the author reviews the whole process he is constrained to say that the factors which determine these processes are still veiled from us. The solution is not to be found in the region of chemistry and physics.

Part II. is perhaps even more interesting and suggestive than Part I. The influence of cell on cell by direct contact, by protoplasmic threads, by nerve fibres, and by internal circulation medium, are all fully considered and well illustrated by woodcuts. Dr. Hertwig lays down a number of propositions which he calls "laws," e.g., the law of "specific energy," that of "physiological division of labour," that of "physiological integration" (following Herbert Spencer), and discusses each with ample wealth of examples. Atrophy, hypertrophy, metamorphosis, metaplasia, and hyperplasia of tissues are then considered, and then degeneration and death of the cell, or necrosis,

One whole chapter is devoted to Weismann's theory of germ plasma. In leading up to a theory of biogenesis the external factors that affect organic development are first considered and then the internal factors. We cannot follow the author into all these complexities, nor can we deal with the factors present in the cell itself, nor the various hypotheses that have been framed to account for them. All we can say is that these several subjects, as well as the whole question of heredity in its widest sense, are all treated in a masterly manner, both as they apply to plants and to animals. An account of the organism that causes malaria, and of trypanosomes and allied organisms which are the cause of specific diseases, is not given. The author has already enough in his text and, perhaps wisely, does not wander into the study of these enchanting fields of investigation.

We warmly commend this work to the attention of naturalists—to zoologists as well as botanists. It is a standard compendium of all that relates to cells and cell life, and should be welcomed by every investigator of "General Biology." To each chapter is appended an excellent list of memoirs dealing with the subject matter.

Rhinology: a Text-book of Diseases of the Nose and Nasal Accessory Sinuses. By P. WATSON WILLIAMS, M.D. Lond., Lecturer on Diseases of the Nose and Throat at the University of Bristol, and in charge of the Departments for Diseases of the Ear, Nose, and Throat at the Royal Infirmary, Bristol; Consulting Surgeon for the Ear, Nose, and Throat, Pontypool Hospital; Vice-President of the Laryngological Section, Royal Society of Medicine, London. With illustrations and stereoscopic plates. London: Longmans, Green, and Co. 1910. Pp. 273. Price 12*s.* 6*d.* net, or with stereoscope 15*s.* net.

THIS book is based on Dr. Watson Williams's earlier work on "Diseases of the Upper Respiratory Passages," and is to be completed by a corresponding volume on Laryngology. As the author points out in his preface, owing to the rapid progress in this specialty during the last few years the amount of space occupied by the text in the present volume is double that which was devoted to the fourth edition of his former work.

The book under review is divided into 14 sections and an appendix. The first section is devoted to the methods of examination of the nose, and the second to its anatomy and physiology, together with that of the accessory sinuses, and a short account of the development. In dealing with the respiratory functions of the nose the author draws attention to the importance of the reflex influence of nasal respiration on the respiratory nerve centres, and points out that one of the causes of mal-development of the thorax in children with adenoids is the absence of the normal respiratory stimuli, resulting in a deficient activity of the respiratory centres. In Section III. the various types of rhinitis are dealt with. Under acute rhinitis Allen's bacteriological investigations are quoted, and the author suggests a careful trial of the vaccine method of treatment. The section on atrophic rhinitis and ozæna is, we consider, disappointing; it is not nearly full enough. The etiology and pathology are dismissed in two pages, and no definite account is given of the histology. The article is practically identical with that published in the author's previous work in 1901, and requires revising and extending. Membranous rhinitis is well dealt with; but under rhinitis caseosa we should like to see an account of the chemical composition of the "cheesy matter," especially as such opposite results on this have been obtained by Dr. Wyatt Wingrave and Mr. Arthur Edmunds. The section on chronic infective diseases of the nose is short but good; we notice, however, that though tuberculin is mentioned as giving good results in lupus, it is not even mentioned under tubercle. The section on diseases of the pharyngeal tonsil is excellent; 14 pages are given to adenoids, and a short paragraph is inserted on status lymphaticus. Section VI. treats of neoplasms of the nose and rhinopharynx. Under mucous polypus the various theories of formation are discussed, and the author enunciates his own lymph-vascular theory, for which he makes out a good case. In this section he also gives an account of an operation devised by himself for the removal of malignant intranasal growths, which gives good access and leaves little or no deformity. The section concludes with a useful table on the differential diagnosis of intranasal growths and infective diseases. Section VII., on diseases of the nasal septum, deals very thoroughly with septal deviations and submucous resection; under the treatment of epistaxis, however, no mention is made of adrenalin or of calcium chloride or lactate. Foreign bodies in the nose and external deformities and their treatment occupy the following two sections. Under the head of nasal neuroses a table of differential diagnosis between cerebro-spinal rhinorrhœa and rhinal hydrorrhœa is included, and the author gives an account of his own successful case of the former treated by repeated lumbar punctures. The article on hay fever is good; amongst other methods of treatment we notice Dr. Watson Williams's advocacy of strong solutions of biniodide of mercury in cases with erectile swelling and vascular injection.

The following sections (XI.–XIII.), devoted to diseases of the accessory sinuses, are amongst the best in the book. The author opens with an inclusive introduction and discusses the etiology, general and objective symptoms. The question of the moral and legal responsibility of patients with sinus suppuration is raised and illustrated with a case from the author's own experience. The subject of pain in sinus suppuration is thoroughly gone into, the author being of opinion that it is due to inflammation of the lining membrane rather than to occlusion of the ostium and over-distension of the sinus. The recent bacteriology of nasal sinusitis is fully quoted. Then follow the symptoms and diagnosis of chronic suppuration in the accessory sinuses and the treatment. Two excellent articles on the skiagraphy of accessory sinuses and the ocular complications of nasal and accessory sinus disease are included. We notice in Plate XVI. that the skiagrams 2 and 3 have been transposed, and in Fig. 113 the description ought to read: "(5) 5th nerve 2nd div." In simple cases of antral suppuration Dr. Watson Williams advocates the alveolar route, thus differing from the majority of English rhinologists. He disapproves of curetting the antrum—unless there is extreme degeneration of the lining membrane—and gives strong reasons for his opinion. In the after-treatment the injection of 1 cubic centimetre of lactic acid bacilli into the antrum is suggested where there is persistent infection. In frontal sinus suppuration the methods of intranasal operation according to Fletcher Ingals and Max Halle are described but not advocated. Various external operations, including Killian's and the author's modified Killian, are fully dealt with. Section XIV. gives a good, short account of the etiology, pathology, symptoms, and treatment of mucoceles and bone cysts in the nasal accessory sinuses. The appendix includes a list of prescriptions, a short account of local anæsthetics, a note on the methods of conducting post-mortem examinations on the nose and nasal accessory sinuses without leaving any facial deformity, and a very good bibliography.

The book is in every way an excellent one and will take its place amongst the leading English text-books on rhinology. The style is simple while the type is clear, and we can cordially recommend it to the specialist, the practitioner, and the student. The printing of the volume and of the illustrations—particularly of the very fine stereoscopic psalet

at the end of the book—are well worthy of the publishing firm who have been responsible for the production.

The Malarial Fevers, Hæmoglobinuric Fever, and the Blood Protozoa of Man. By CHARLES F. CRAIG, M.D., Captain, Medical Corps, United States Army. Illustrated by 4 Coloured Plates, 24 Charts, and 28 Photomicrographs and Drawings. London: J. and A. Churchill. 1909. Pp. 477. Price 20*s.* net.

THIS volume, which is dedicated to the Medical Corps of the United States Army, is largely the outcome of the author's personal experience gained in the military hospitals of America, Cuba, and the Philippines. It embodies the results of over ten years of investigation, and the observation of thousands of cases of malarial fever. Captain Craig states in his preface that he has endeavoured to record in this work all the important advances and facts of interest to the student and clinician; in doing this he has consulted a mass of literature, of which he supplies at the end of each chapter a copious list of references. The book is divided into seven parts, the first five occupying some 380 pages, being devoted to malarial fevers, their etiology, general and special pathology, symptomatology, and clinical varieties, their sequelæ, complications, and prognosis, and their diagnosis, prophylaxis, and treatment. The subject of hæmoglobinuria, or blackwater fever, is discussed in some 17 pages, while the blood protozoa of man are considered in about 50 pages. These protozoa include the parasites of kala-azar, sleeping sickness, and relapsing fever, and a brief description is also given of Histoplasma capsulatum, an organism associated with a disease resembling kala-azar discovered by Darling on the Isthmus of Panama. Owing to the fact that our knowledge of protozoal parasites is growing so rapidly day by day it was almost inevitable that some of the author's statements should require revision soon after they were published. For instance, in writing of the transmission of sleeping sickness by the Glossina palpalis he says: "So far as we know, the infection is carried from the sick to the well by the proboscis of the fly, as no evidence exists that trypanosomes undergo any development within the insect, and the fly is not infective after 48 hours." The recent researches of Kleine and Bruce show, on the contrary, that the parasite does undergo a cycle of development in the Glossina, and that the insect retains its power to infect for many months, if not for the rest of its life. As regards blackwater fever, the author believes that it is a disease "*sui generis*" produced by a parasite probably of a protozoal nature, though he admits that there is as yet no direct evidence to support this view. The book contains a vast amount of information respecting malarial fevers, and it should prove of great service to all those who are concerned with the treatment and prevention of this widespread and serious class of diseases.

LIBRARY TABLE.

A Surgical Handbook for the Use of Students, Practitioners, House Surgeons, and Dressers. By FRANCIS M. CAIRD, M.B. Edin., F.R.C.S. Edin., Professor of Clinical Surgery, University of Edinburgh; and CHARLES W. CATHCART, M.B. Edin., F.R.C.S. Eng. & Edin., Surgeon, Royal Infirmary, Edinburgh. With very numerous illustrations. Fifteenth edition, revised. London: Charles Griffin and Co., Limited. 1910. Pp. 331. Price 8*s.* 6*d.*—Surely the fact that a work has reached a fifteenth edition is sufficient in itself to show that it has supplied a want so definite as to place the book practically beyond criticism. We have on many previous occasions expressed our deep appreciation of the value of this little work. Much that is needed in practice is not to be found in the regular text-books of surgery. Part of this the student learns from his teachers, but the deficiencies in his knowledge become strikingly manifest when he has to undertake treatment on his own account, and it is in supplying the deficiencies of the ordinary text-book that this handbook is specially valuable—a quality which accounts fully for the great success it has attained. The present edition shows several changes, and the chief of these is the addition of an account of spinal anæsthesia. The book should prove of the greatest value to all engaged in the study of surgery.

A Guide to the Study of the Specimens in the Sections of Obstetrics and Gynæcology in the Museum of St. Bartholomew's Hospital. By HERBERT WILLIAMSON, M.A., M.B. Cantab., M.R.C.P. Lond., Assistant Physician-Accoucheur; and REGINALD JAMISON, M.A., M.B. Oxon., F.R.C.S. Eng., Junior Demonstrator of Pathology. London: Adlard and Sons. 1909. Pp. 294. Price 5*s.* net.—The plan of combining a museum catalogue and a manual is a good one if it is well carried out and the two parts are kept in their proper relation to one another. The majority of pathological museums at the present day contain so large a number of specimens that unless a part of the collection is set aside for the purposes of teaching it is not possible for the student to derive much good from the series as a whole. In every large museum there must of necessity be a number of specimens which, although interesting to the pathologist or to the teacher, yet differ but little from one another and are of only slight value to the student. For this reason a guide such as this one written by Dr. H. Williamson and Dr. R. Jamison is of the greatest value to the student. The book is divided into two parts dealing with obstetrics and gynæcology, each section contains a full account of the various affections described, the text being illustrated by the descriptions of the various specimens in the museum of the condition under discussion. We are not told whether the book is a catalogue of the whole of the collection or only of those specimens considered by the authors to be representative and such as the student should be familiar with. The explanatory matter is well written, and, so far as we can judge, the descriptions are brief and to the point. It is a pity that so comparatively few of the specimens appear to have any clinical history referring to them. We notice two errors in the spelling of proper names—viz., Gärtner for Gartner, and Nück for Nuck—and as the former is a very common error made by many writers, even appearing in the last edition of Quain's "Anatomy" in the volume on Embryology, we may be pardoned for referring to them in a little detail. Gartner and Gaertner are two different people. Gartner, the original describer of Gartner's duct in the cow, was a Dane and, we believe, a professor in Copenhagen, while Gaertner was a German and did not describe Gartner's duct.[1] Antonius Nuck was a Dutchman and was born at Harderwyk in the year 1650. He was professor of anatomy and medicine at Leyden University in 1687, to which school many students were attracted by his anatomical lectures. He was the author of "Adenographia Curiosa et Uteri Foeminaei Anatome Nova," and it was he who gave his name to the canal of Nuck.

Social Disease and Its Prevention. By H. N. ROBSON, M.R.C.S. Eng., L.R.C.P. Lond. Second edition. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1909. Pp. 104. Price 3*s.* 6*d.* net.—This short book gives an account of a study of the effects of venereal disease, meaning by this title both syphilis and gonorrhœa. Mr. Robson has visited 62 countries and islands, and so has had plenty of opportunities for observing both the diseases and the measures adopted to minimise their evils. His book is the outcome of a conviction "that the remedy for venereal

---

[1] See Waldeyer Das Becken, p. 529.

diseases was not legislation directed against one sex only, but prophylactic or preventive treatment by the individual without any legislation whatever." The method which he recommends is that officially recommended in both the French and German military and naval services—namely, the employment of a mercury ointment and an injection containing either protargol or potassium permanganate after exposure to infection, or if possible before. The evil effects of both syphilis and of gonorrhœa are so widespread and of such importance to the State that the arguments for such measures as the two above-mentioned Governments have taken are very forcible as long as such measures have none of the undoubtedly very objectionable features of a *Police des mœurs*.

JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by J. N. LANGLEY, Sc.D., F.R.S. Vol. XL., Nos. 3 and 4. London: C. F. Clay, Cambridge University Press. May 13th, 1910. No. 3, price 9*s.*; No. 4, price 4*s.*—The contents of No. 3 are: 1. The Gaseous Metabolism of the Small Intestine; Part I., The Gaseous Exchanges during the Absorption of Water and Dilute Salt Solutions, by T. G. Brodie, M.D., F.R.S., and H. Vogt, M.D. This is a long and carefully drawn-up article, giving the results of many analyses of the intestinal blood and gases of the intestine in dogs under an anæsthetic, from the physiological laboratories of the London School of Medicine for Women and of the Royal Veterinary College, London. Part II., The Gaseous Exchanges during the Absorption of Witte's Peptone, by T. G. Brodie, W. C. Cullis, D.Sc., and W. D. Halliburton, M.D., LL.D., F.R.S., from the same laboratories as in the preceding article. The experiments were a continuation of the experiments there described. 2. A New Mathematical Treatment of Changes of Ionic Concentration in Muscle and Nerve under the Action of Electric Currents, with a Theory as to their Mode of Excitation, by A. V. Hill, B.A., Scholar of Trinity College, Cambridge, George Henry Lewes Student—a highly technical article that few except professed mathematicians could follow. 3. An Analysis of Changes and Differences in the Excitatory Process of Nerves and Muscles, based on the Physical Theory of Excitation, by Keith Lucas, Fellow and Lecturer of Trinity College, Cambridge. 4. The Delay of the Electrical Response of Nerve to a Second Stimulus, by Francis Gotch, M.A. Oxon., F.R.S., from the Physiological Laboratory, Oxford. 5. The Alleged Formation of Adrenine from Tyrosine, by E. J. Ewins and P. P. Laidlaw, from the Wellcome Physiological Research Laboratories. This number also contains the Proceedings of the Physiological Society for March 19th, 1910.

The contents of No. 4 are: 1. On the Significance of Carbon Dioxide for the Heart-beat, by E. Jerusalem and E. H. Starling, from the Institute of Physiology, University College. The authors show that any increase in the CO_2 tension in the blood of the coronary arteries causes both systolic and diastolic relaxation of the volume of the heart. With high percentages (12 to 20 per cent. of an atmosphere) the systolic cardiac dilatation is greater than the diastolic. With moderate tensions of CO_2 (2 to 8 per cent. of an atmosphere) the ventricular output increases with increase in the CO_2 tension. Increase in the CO_2 tension tends to slowing of the isolated heart. There is a certain optimum tension of the CO_2 in the blood at which the cardiac output is at its maximum, and this optimum probably rises with fall of temperature of the blood circulating through the coronary vessels. 2. The Respiration of the Tortoise Heart in Relation to Functional Activity, by H. M. Vernon, from the Physiological Laboratory, Oxford. Mr. Vernon shows that tortoise heart when perfused continuously with oxygenated Ringer's solution retains its vitality for as long as 105 hours, the rate of beat and output of CO_2 gradually falling. The effects of NaCl, HgCl, NaFl, formaldehyde, HCN, and with $NaHSO_2$ are described. 3. Some Colour Reactions of Adrenine and Allied Bases, by A. J. Ewins, from the Wellcome Physiological Research Laboratories. Mr. Ewins states that the colour reactions for adrenine hitherto described as the iodine reaction of Vulpian, the mercuric chloride reaction of Comessatti, and the bi-iodate reaction of Fränkel, are due wholly or in part to oxidation. Other closely related bases give similar colour reactions. 4. The Action of Beryllium, Lanthanum, Yttrium, and Cerium on the Frog's Heart, by George Ralph Mines, Fellow of Sidney-Sussex College, Cambridge, from the Physiological Laboratory, Cambridge.

Edinburgh Medical Journal.—The use and possible abuse of athletics at school are discussed by Dr. Thomas M. Burn-Murdoch in an introductory address published in the May issue of this journal. In this and in the discussion which followed it was generally held that the amount of harm done was small, while the good that resulted was conspicuous. Dr. A. W. Falconer writes on some cases of regular slow pulse, and contrasts cases in which the whole action of the heart is slow with others in which there is failure of transmission of stimulus from auricle to ventricle. Mr. Alexander Don, in a paper on Cancer of the Colon, notes the resemblance of many such cases to pernicious anæmia and the good results obtainable by surgical interference. A series of excellent skiagrams illustrates an article by Dr. George A. Pirie on Diseases of Bones and Joints as shown by the X rays; and a brief note by Dr. T. Shennan describes the method of demonstrating the spirochæta pallida and similar organisms by means of Indian ink which makes an artificial dark field for the purpose (Burri's method).

Dublin Journal of Medical Science.—In the April issue Dr. R. Travers Smith and Dr. H. C. Earl record a case of Acute Leukæmia; Dr. M. Orb, of Erlangen, writes on the Physico-therapy of Sciatica, and notes how such procedures may be carried out even apart from special institutions; and Professor A. E. Mettam gives an account of the disease of animals called Piroplasmosis and of experimental work directed to the discovery of a mode of immunisation against the malady. In the May number Mr. Maurice R. J. Hayes reports a case of Spleno-medullary Leukæmia treated by X rays with temporary benefit, and describes his method for applying the treatment. Dr. William A. Winter records a case of diabetes in a woman who had previously suffered from exophthalmic goitre, and Dr. W. M. Crofton describes a case of diabetes treated by a special extract of pancreas. Dr. T. Percy C. Kirkpatrick gives an interesting historical account of the methods used for prevention of small-pox before the discovery of vaccination down to the time of Haygarth of Chester in the eighteenth century; a continuation of the article is promised.

Birmingham Medical Review.—In the April issue Dr. Leonard G. Parsons records four cases of polio-encephalitis affecting the "cerebello-rubro-spinal" system and causing a peculiar form of tremor first described by Miller; and Dr. R. Beatson Hird discusses optic neuritis in relation to intracranial growths and its treatment, which should be by surgical interference at the earliest moment, for the relief of pressure. In the May number Mr. Percival P. Cole publishes some remarks on the suprarenal capsules, pointing out the connexion between the existence of hypernephromata and premature sexual development and the close relationship between these glands and the sexual apparatus. The subject

of Puerperal Infection is dealt with in an introductory address by Dr. Mary A. D. Scharlieb, in which, as well as in the discussion following, the removal of the uterus for this condition is held to be unadvisable, while favourable opinions are expressed with regard to serum-treatment.

Medical Chronicle.—Two articles on the surgery of the tonsils appear in the May number of this magazine. In the first, Dr. William Milligan deals with the anatomy of the organ and the best mode of removing it, for which purpose enucleation is preferable to tonsillotomy and a special procedure is recommended. In the second, Mr. Alexander Wilson discusses the choice of an anæsthetic for tonsillotomy and advises the A.C.E. or C.E. mixture. Dr. Arthur Latham deals with the duties of municipalities in relation to consumption, and Dr. N. J. H. Gavin calls attention to some problems of modern psychiatry in the form of a review of Professor Lugaro's book, now translated by Dr. David Orr and Dr. R. G. Rows.

THE LANCET LABORATORY.

SAUERIN LIQUID CULTURE.

ALLEN AND HANBURYS, LIMITED, 37, LOMBARD-STREET, LONDON, E.C.)

WE have tried the effect of sauerin liquid culture upon milk and the result was one of the best we have obtained. At the end of 24 hours the milk was completely clotted and the clot had a homogeneous regular consistence. There were no lumps present. Meanwhile, tests for acidity showed that it had increased sevenfold in 24 hours. The admirable results given by this preparation is doubtless due to the fact that it is a pure active culture of the Metchnikoff Bulgarian bacillus. The same bacillus is contained in tablets which afford a convenient way of employing the sour milk treatment. Messrs. Allen and Hanburys supply also a well-designed apparatus for incubating the milk at the requisite temperature. It consists of a jar with lid, which is placed in a metal container supported on a stand. Beneath is a night-light and over the flame is a baffle which distributes the heat uniformly through the container and round the jar in which the milk to be soured is placed.

*REGULIN.

(THE REGULIN SYNDICATE, LIMITED, 13, CULLUM-STREET, LONDON, E.C.)

Regulin provides for the rational treatment of constipation, since it is composed principally of agar-agar, which swells into a soft mass in the alimentary tract, emerging unchanged in the fæces, which, owing to the presence of the jelly, acquire a larger proportion of water, and so are softened and evacuated without difficulty. A small proportion of cascara extract present assists the action. The method of treatment is of interest, and we may expect to receive some clinical reports upon its results. Regulin occurs in reddish-brown flakes, but it is conveniently prepared also in the form of tablets. It is practically free from any flavour.

(1) VACCINES; (2) ADRENALIN GAUZE TAPE; (3) AMPOULES OF ADRENALIN SOLUTION; AND (4) TUBERCULIN (OLD).

(PARKE, DAVIS, AND CO., BEAK-STREET, REGENT-STREET, LONDON, W.)

1. We have received specimens of influenza bacillus vaccine and of pneumococcus vaccine, both of which are prepared in the vaccine laboratory of the department of therapeutic inoculation at St. Mary's Hospital, under the direction of Sir Almroth Wright. The influenza bacillus vaccine is prepared from cultures isolated from cases of acute influenza or chronic bronchitis, the vaccine being applicable not to every case of influenza, but only to those in which the presence of the bacillus has been ascertained. Similarly, the pneumococcus vaccine is applicable to the treatment of croupous pneumonia, also bronchial colds, and chronic bronchitis, in which pneumococcus infection is present, and is the predominant factor. These vaccines must, of course, be controlled by the usual methods. 2. The sterilised adrenalin gauze tape is of obvious service to the surgeon as a hæmostatic dressing. The edges of the tape are selvedged, so that the annoyance of loose strands is avoided. 3. The ampoules of adrenalin solution, 1 in 10,000, are prepared to meet the demand of the physician or surgeon who desires to use a weaker solution than the original strength introduced (1 in 1000). 4. Specimens of capillary tubes containing undiluted (old) tuberculin have been submitted to us. A small pneumatic bulb for expelling the fluid from the tube drop by drop is provided, together with a nickel-plated scarifier for preparing the skin previously to applying the test in von Pirquet's method for diagnosing tuberculosis.

HOOKER'S MILK COCOA.

(THEW HOOKER AND GILBEY, LIMITED, BUCKINGHAM, AND DONNINGTON HOUSE, 30, NORFOLK-STREET, STRAND, LONDON, W.C.)

We reported upon this preparation last year, but it has since been modified in the direction of increasing the carbohydrates. We find now that as much as 76 per cent. of the cocoa is soluble in water. Amongst these soluble substances are milk protein, milk sugar, and cane sugar. The amount of theobromine yielded was 0·2 per cent., which is equivalent to about 11 or 12 per cent. of cocoa. According to the estimation of milk sugar the preparation contains about 40 per cent. of milk solids. The amount of protein was 11·46 per cent. It will thus be seen that the cocoa contains all classes of nutritive substances, in addition to which it is a useful and agreeable stimulant.

INFANT FOOD.

(JOHN WILSON, 199, MAIN-STREET, WISHAW.)

We find no novelty in this preparation, nor anything in regard to its composition calling for special remark. It is a farinaceous food which has obviously been malted. It yields 18·80 per cent. of soluble matters to cold water which consist principally of maltose. The food is practically free from fat, but this is compensated for by the direction to use milk in its preparation.

HONEYCOMB MOULD.

(THE SUNSHINE CUSTARD CO., GRAPE WHARF, NARROW-STREET, LIMEHOUSE, LONDON, E.)

We presume this preparation is useful for certain purposes, but it presents no special feature or anything calling for particular appreciation from us. According to our examination, it contains merely gelatin, sugar, and flavouring materials. When dissolved in warm water it sets into a firm jelly which has a sweet taste, and certain flavouring materials are present also.

SANITARY SLATE PENCILS.

(THE KIDDERMINSTER PENCIL COMPANY, COVENTRY-STREET, KIDDERMINSTER.)

These pencils are said to contain a definite quantity of a well-known germicide (Cyllin). The idea is a good one, for in more than one direction the use of the slate has sanitary objections. Apart from the spreading of a germicide on the slate, so far as the writing covers it, it must be remembered that the pencil is oftentimes sucked. Of course, on the removal of the writing by the application of a wet sponge, the disinfectant is rubbed over the entire surface of the slate. This innovation meets to some extent the objections to the use of the slate on sanitary grounds. Certainly the slate is more easily disinfected than a paper sheet. The continual smell, however, of coal-tar compounds is not always agreeable.

New Inventions.

A NEW PORTABLE OPERATING TABLE.

THE accompanying illustrations show a new portable form of operation and clinical examination table which I have used for some time and consider to be a great improvement on the models hitherto existing. It is light, weighing only about 40 pounds complete; very portable, measuring when folded up 30 × 20 × 5 inches, so that it can quite easily be placed inside or on the top of a motor car or carriage; and very strong, being manufactured from oak (varnished with hard varnish) and steel (nickel plated). All joints and working parts are made of metal. It is adjustable to almost any position, and the portion, of the table which supports the patient's legs is made to adjust to any angle, in order to reduce the pressure on the popliteal spaces to a minimum. The head part of the table can be very easily raised or lowered. It will be found to be a very useful table for surgical or gynæcological operations and clinical examinations, especially when the administration of an anæsthetic is necessary, or when it is wished to use a cystoscope, urethroscope, sigmoidoscope, œsophagoscope, or bronchoscope.

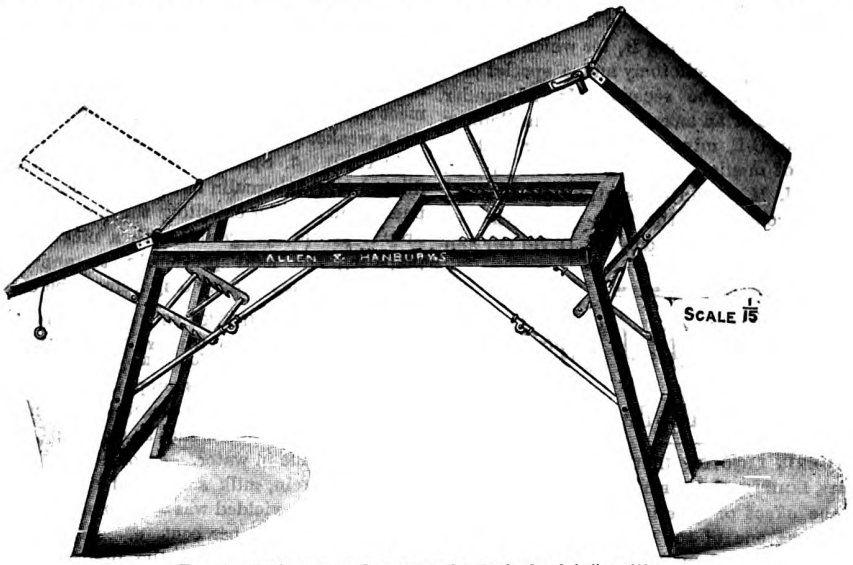

FIG. 1.—Table open and arranged for "raised pelvic" position.

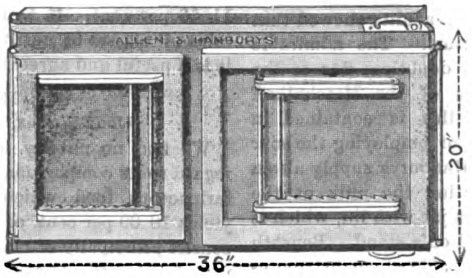

FIG. 2.—Table closed.

Messrs. Allen and Hanburys, Limited, 48, Wigmore-street, Cavendish-square, London, W., are the makers.

ROYAL INSTITUTION.

Friday, May 11, 1832.

SPARKS FROM MAGNETS.

Dr. Richie, professor of natural philosophy to the institution, this evening stated that he had followed in the track of Mr. Faraday in his late brilliant discoveries, and was happy to say he had uniformly arrived at the same conclusions. He had also succeeded in making the spark, which had been obtained by Mr. Faraday in breaking the magneto-electric circle, visible to a large assembly. This was done by placing an explosive mixture of oxygen and hydrogen in the course of the spark, which immediately produced a loud report and a flash of light. He employed a horse-shoe magnet, between the ends of which were placed a couple of tubes; a wire was introduced into each, and their connexion maintained by a conducting medium. The wires were connected to the magnet by the folds of copper ribbon. The gas was introduced by a bladder and stopcock. The contact suddenly broke, and the spark was made evident by an explosion. Dr. Richie declared his belief that no spark could be elicited from any but a *temporary* magnet.

At this time Mr. Faraday came forward, and stated he had succeeded in obtaining a spark from a natural magnet. Mr. Faraday had borrowed Brown's magnet from the Academy at Woolwich. A small bar of iron, about six inches long, was used in contact with the extremities of the magnet. Two connecting wires were raised from each end of this small bar, and being bent at right angles, overlapped each other. The undermost terminated in a disc about the size of half-a-crown. By a rapid percussion of the bar against the magnet, the disc and wire broke in contact by their elasticity, and a beautiful bluish spark was rendered evident amidst the merited applause of the spectators. During these transactions, as pretty a scene of philosophical coquetry was enacted between the two experimentalists as was ever exhibited on any stage. But the good-natured and discriminating audience would pardon that and much more, in men of such transcendent merit as Richie and Faraday.

In the library there was nothing worthy of remark, except specimens of a petrified *jungle* of gum, and other trees from the New Hebrides.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

WEDNESDAY, MAY 25TH.

THE Council resumed its sittings at its offices, 299, Oxford-street, W. Sir DONALD MACALISTER, the President, again occupied the chair.

Penal Cases.

The Council during the sitting dealt with penal business.

The first case to come under consideration was that of David Thomas Jones, registered as of Rock House, Wostenholme-road, Sheffield, Mem. R. Coll. Surg. Eng., 1890, Lic. R. Coll. Phys. Lond., 1890, who was summoned to appear before the Council on the following charge, as formulated by the Council's solicitor:—

That you have knowingly authorised or allowed an unqualified and unregistered person—namely, one William Perry—to attend patients in your name and on your behalf, and in particular to attend one Alice Hannah Nicholson in her confinement, and subsequently to fill in for the signature of Joseph Nicholson, her husband, the notification of birth required by the statute containing, amongst other particulars, the statement that you were the doctor attending the case.

And that in relation thereto you have been guilty of infamous conduct in a professional respect.

Mr. Jones appeared in answer to his summons, and was defended by Mr. H. T. Waddy, instructed by Mr. E. Wing, solicitor, Sheffield.

The complainants were the British Medical Association, who were represented by Mr. J. Smith Whitaker, the medical secretary, who was accompanied by Mr. Hempson, solicitor.

The PRESIDENT at the outset said that as the complainants were the British Medical Association he would warn any members of the Council who were members of the Association not to take part in the hearing or determination of the case.

Sir WILLIAM WHITLA said that as President of the British Medical Association he would withdraw and take a seat in the gallery.

Dr. Saundby, Dr. Dixon Mann, and Dr. Newsholme, as well as Sir William Whitla, withdrew from the proceedings.

Mr. SMITH WHITAKER then addressed the Council on behalf of the complainants. He said that the case was one of considerable public interest and importance. In the first place he spoke of the reasons which had led the British Medical Association to take up the case. Dr. H. Scurfield, the medical officer of health of Sheffield, felt that it was not his duty to appear as complainant. The coroner did not think it his duty. The matters connected with the case were brought before local practitioners. They thought that the circumstances in which Mr. Perry was employed by Mr. Jones should be brought before the Council, but they felt that if they appeared as complainants they would be open to reflections of personal and professional jealousy. However, it seemed to the British Medical Association that the case should be brought before the Council. The facts of the case were comparatively simple, and from the statement which had been put in by Mr. Jones it appeared that the main circumstances of the attendance on Mrs. Nicholson were hardly in dispute. It appeared that Mr. Jones had agreed to attend Mrs. Nicholson in her confinement, that he saw her on several occasions in the month preceding the confinement, but on the day of it he was unable personally to attend. William Perry was his dispenser, but he held no medical qualification of any kind. No partner of the practice being available, Perry attended the woman on Saturday, July 24th, 1909, and delivered her of twins. He left word that Mr. Jones would attend on the next day. Mr. Jones was unable to attend, and Perry attended again. Mrs. Nicholson was not seen by Mr. Jones from the Saturday until the Wednesday, nor by any registered medical practitioner. On Wednesday Mr. Jones called and found her in a dangerous condition. He advised that the only chance for her life was that she should be removed to some institution, and she was, in fact, removed to Ecclesall Infirmary, where she died. He would not dwell in any detail on the gravity of the case, or on the fact that the woman died following upon confinement in which she was attended by Mr. Perry. The question which the Council was trying was the action of Mr. Jones in allowing Mr. Perry to attend professionally on his behalf. The gravity of the case so far as the Council was concerned was a registered practitioner allowing himself to be represented by an unqualified person. The matter came under the notice of the medical officer of health of Sheffield through one of the inspectors of midwives who visited the house and reported the circumstances to the medical officer of health. Dr. Scurfield, the medical officer of health, noted in the notification of birth that the medical man in attendance was Mr. Jones. From the inspector's report it appeared that the woman had been attended by Mr. Perry. He (Dr. Scurfield) wrote for an explanation. Afterwards he sent a statement to the coroner. An application was made to the Home Secretary for the exhumation of the body. An inquest was held. A great part of the evidence consisted of the depositions made at the inquest. The coroner's jury, whilst finding that death was due to natural causes, expressed the opinion that it was not proper that this woman should not have been attended by a qualified practitioner, having regard to the circumstances. In bringing the case forward the British Medical Association felt the public danger of medical practitioners being allowed to substitute for their services the services of unqualified persons.

Mr. F. E. NEWTON, clerk to the coroner; Mr. W. SWALLOW, confidential clerk to the medical officer of health, Sheffield; and Mr. A. K. GALE, a registered medical practitioner of Sheffield, gave evidence in connexion with the case.

Dr. HAROLD SCURFIELD, medical officer of health, Sheffield, also gave evidence. He explained his duties in regard to the Notification of Births Act and the Midwives Act. He had 15 women inspectors under him, whose duties were largely in connexion with the births attended by midwives. The notification of the births in the case now before the Council was received on July 26th. The date of the births was given as July 24th. The name of the medical attendant was given as Mr. D. T. Jones. On July 29th he received a notification from one of the medical officers of the Ecclesall Infirmary that Alice Nicholson had been admitted to the hospital suffering from a disease that ought to be notified to him. As the result of a visit of an inspector it appeared that the woman had not been attended at her confinement by a medical man at all. He wrote to Mr. Jones asking him to give an explanation as to the medical man who attended Mrs. Nicholson and why no notification of the disease was made. He received no reply. He communicated with the coroner. The body was exhumed and there was an inquest. The coroner said that he had held the inquest to see how the woman met her death. He had written to the General Medical Council, as the question of covering was likely to arise. The reply was that the Council did not act without a complaint. The question which concerned him was that women should be properly attended to on confinement, but he admitted that he had a strong feeling that it was absolutely unfair that unqualified women should be prosecuted when bad results ensued and unqualified men should go scot free.

Cross-examined by Mr. WADDY, Dr. SCURFIELD said that he had no feeling against Mr. Jones. He had been told that this complaint was suggested by professional jealousy. He had come to the Council to say that the action taken was due to his own efforts uninspired by anybody in Sheffield.

Was it fair to go and make statements to the coroner's officer without having any answer from Mr. Jones?—I do not see what else I could do.

Witness proceeded to state that afterwards Mr. Jones wrote and explained that he had been away for a five weeks' holiday. He explained that the woman was removed an hour after he saw her, and he thought that as the medical officer at the infirmary would notify the case there was no need that he should do so also.

Re-examined, witness said that he thought the inquest ought to be held as soon as possible.

This concluded the complainant's case.

Mr. DAVID THOMAS JONES gave evidence in his own defence. Examined by Mr. WADDY, he stated that he had

carried on his practice for about 20 years. It was in the main a working-class one, and he now had three partners. Since the difficulty in regard to Mrs. Nicholson he had kept a qualified assistant. Mr. Perry had been engaged for two years as surgery attendant and dispenser for the partnership, but at no time had Perry been allowed to do consulting work or visiting work in the ordinary sense. Perry had been present at 300 confinements before he came to him, but he had not attended any since he came into his (Mr. Jones's) service unless one or other of the partners of the practice was present at the same time. In an emergency, such as an accident at one of the works in the neighbourhood, when none of the partners were at hand Perry would make preparations for them when they arrived.

Has he done anything except making preparations?—No.

Is it true that Perry has prescribed for patients?—No, that is not true.

Mr. JONES went on to say that he was still in attendance on the Nicholsons. He had attended Mrs. Nicholson and from June 16th to July 21st he had paid her 17 visits. He now knew that Perry on receiving a message went off to see the case, and he afterwards heard from him that he had found the woman in labour and delivered her. He also was informed that the labour was natural and proper and he made a note of the case so that he should see the patient on the 25th. It was his intention at the same time to leave a notification form to be filled in. He was prevented from carrying out his intention by the urgency of another case. He sent the form and Perry told him that when he asked that the form should be filled up, Nicholson asked him (Perry) to fill it up for him and at the same time he asked him to go upstairs and see the patient.

But for the call to another confinement you would have carried out your intention to see Mrs. Nicholson that evening?—Yes.

Witness went on to say that he heard that Mrs. Nicholson was getting on well. On the Tuesday he had been to an operation, and after the operation he drove in the direction of Mrs. Nicholson's house. On his way he called on another patient, and he thought that her case was of such a nature that it would be very dangerous for him to go to Mrs. Nicholson direct. He was called to see her on Wednesday. He found the patient had become so ill that she ought to be removed to a hospital, and she was sent within an hour.

By sending this woman to a public institution you must have appreciated the inquiries that would follow with regard to the treatment before she went there?—Yes.

Since this matter has become a matter of comment you have engaged a qualified assistant?—Yes.

This matter cannot occur again in your practice?—No.

Mr. SMITH WHITAKER (cross-examining): Your idea was that it was better that this unqualified person, Mr. Perry, should keep on the spot to render any assistance in an emergency case?

Mr. JONES: Yes. The place is surrounded by works, and our idea was that Mr. Perry should prepare the case for us.

He never rendered any medical assistance?—No.

Why did he deliver this woman?—Well, I suppose he knew she was under my treatment.

This was the only labour case Perry ever attended, except in presence of one of the partners?—That is so.

You relied on Perry's report in this case?—Yes.

It is a coincidence that the only case in which Perry attended on your behalf should have landed in a coroner's inquest and an inquiry before this Council?—Yes.

Mr. WADDY then addressed the Council on behalf of Mr. Jones. He expressed the view that quite an undue amount of importance had been attached to the filling in of the birth notification form. Some one had got a little hysterical about the case. The proceedings in regard to the inquest were set on foot before Mr. Jones had had an opportunity of offering any explanation, and he thought that on that ground he had a just grievance. A medical man might misunderstand the rules of his profession when they were put into language which was ambiguous in its terms. If Mr. Jones's opinion of them had been formed under circumstances where he had striven to keep within the regulations of his profession the Council ought to be very slow to say that he had been guilty of infamous conduct in a professional respect. As to the statutory notification of birth, the requirement was that the father of the child and not the medical man should fill in the form. He should not have thought that it was an improper thing for Mr. Perry to fill in the form.

Mr. SMITH WHITAKER, in reply, said that the question was whether Mr. Jones was justified in allowing Mr. Perry to attend Mrs. Nicholson on the day of her confinement. When Perry attended on the Saturday when Mr. Jones was out, that ought to have been the last occasion on which he attended. When Mr. Jones found himself unable to attend on the Sunday or Tuesday, and none of his partners could do so, he should have asked some member of the medical profession to attend for him. Possibly Mr. Jones had not had an opportunity of becoming acquainted with the report of the Council to the effect that it was a fraud upon the public for a medical practitioner to substitute the services of an unregistered person for his own services. The whole of this case illustrated, from the point of view of the British Medical Association, the want of appreciation that still existed in the minds of some members of the medical profession of the importance of the Council's pronouncements on the subject of the attendance by unqualified persons on behalf of qualified persons. The Association had no animus against Mr. Jones, but in taking action it had a public duty to perform.

After consideration of the case *in camerâ*,

The PRESIDENT said: Mr. David Thomas Jones, I have to inform you that the Council have judged you to have been guilty of infamous conduct in a professional respect, and have directed the Registrar to erase from the Medical Register the name of David Thomas Jones.

The next case on the programme of business was a charge against a medical man for having associated himself with a friendly society which, it was alleged, systematically practised canvassing for the purpose of procuring patients. However, a statement was made to the effect that when he discovered that canvassing was taking place he gave up his connexion with the society. The Council permitted the case to be withdrawn, without the charge being formally placed before it.

The Council adjourned.

THURSDAY, MAY 26TH.

The Council resumed its sittings at its offices, 299, Oxford-street, W. Sir DONALD MACALISTER, the President, was again in the chair.

Appointment of Committees.

On the motion of Dr. NORMAN MOORE, seconded by Mr THOMSON, the nominations of the branch councils for the Education Committee, the Examination Committee, and the Public Health Committee were adopted. These committees are therefore constituted as follows:—

Examination Committee.—Dr. Taylor, Dr. Saundby, and Dr. Caton (nominated by the English Branch Council), Sir Thomas Fraser, Dr. Finlay, and Dr. McVail (nominated by the Scottish Branch Council), and Sir John Moore, Sir Charles Ball, and Dr. Kidd (nominated by the Irish Branch Council).

Education Committee.—Dr. Norman Moore, Sir G. Philipson, and Sir J. Williams (nominated by the English Branch Council), Dr. Mackay, Mr. Hodsdon, and Dr. Knox (nominated by the Scottish Branch Council), and Sir T. Myles, Sir C. Nixon, and Dr. Little (nominated by the Irish Branch Council).

Public Health Committee.—Dr. Cocking, Dr. Newsholme, and Dr. McManus (nominated by the English Branch Council), Dr. Norman Walker, Sir J. Tuke, and Dr. McVail (nominated by the Scottish Branch Council), and Sir John Moore, Dr. Adye-Curran and Dr. Kidd (nominated by the Irish Branch Council).

Penal Cases.

The Council resumed consideration of penal cases. The case first to come before it was that of Charles Lyddon, registered as of 26, East Beckett-street, Burmantofts, Leeds, Mem. R. Coll. Surg. Eng., 1865, Lic. R. Coll. Phys. Edin., 1873, Lic. Soc. Apoth. Lond., 1873, who was summoned to appear before the Council on the following charge as formulated by the Council's solicitor:—

That you have knowingly associated in practice with an unqualified and unregistered person, namely, one Charlton Forman, and in particular—

(1) That you have knowingly authorised or allowed the said Charlton Forman to exhibit his name at your surgery at 26, East Beckett-street, Leeds.

(2) That you have knowingly authorised or allowed the said Charlton Forman to attend and prescribe for patients in your name and on your behalf and to sign in your name documents purporting to be medical certificates of the unfitness of children to attend school without having yourself attended the children, and thereby have enabled the said Charlton Forman to act in relation to these cases as if he were a person duly qualified and registered. In particular, the said Charlton Forman has attended and prescribed for, and has signed in your name, such certificates in respect of the following persons—namely, Jessie Wain, Hilda Wain, Herbert Plant, Florrie Garrett, and John William Akeroyd.

And also on the following charge :—

(3) That you have knowingly authorised or allowed the said Charlton Forman to fill up and sign in your name on the forms supplied by the Registrar of Births and Deaths two certificates of the cause of death—namely, in the cases of Gertrude Renoncie and Ernest Woolford—certifying that you attended each of such persons in her and his last illness and when you last saw each of them alive, whereas in fact you had not attended the said Gertrude Renoncie or seen her during her illness, but the said Charlton Forman had alone attended her, and that you had only visited the said Ernest Woolford alternately with the said Charlton Forman. And that in relation thereto you have been guilty of infamous conduct in a professional respect.

The case was originally brought to the notice of the Council by the City of Leeds Education Department.

Mr. LYDDON attended in person, but he was not accompanied by a legal adviser.

Mr. WINTERBOTHAM, the Council's solicitor, made a statement to the Council on the circumstances out of which the case arose, The evidence would show that Mr. Lyddon's registered address, 26, East Beckett-street, had since 1905 been rented by Forman. The profits were shared by Mr. Lyddon and Forman. It could be proved conclusively that until notice was sent by the Council's Registrar every school certificate that had been given from the surgery had been signed in Mr. Lyddon's name by Forman. There was not a single certificate signed by Mr. Lyddon himself. As to the death certificates he would produce the books with the counterfoils of the certificates of death. There were not many of these filled in, but he believed that it would not be questioned that for the last five years he had signed 30 certificates of death every year in the name of Mr. Lyddon. When the Registrar wrote to the accused practitioner for an explanation a letter was received in reply in which it was stated that Forman was the dispenser and surgery attendant, that he had signed four or five certificates, and that Mr. Lyddon had reprimanded him very severely and promised that the thing would not happen again. That was written by Forman. In a later letter Mr. Lyddon stated that Forman's name was on the door for the convenience of the postal authorities. He (the solicitor) would put it to the Council that the name was on the door because the premises were his own. The wholesale giving of certificates was brought to the notice of the authorities, and a prosecution was instituted against Forman. The jury having found him guilty recommended him to mercy, and he was fined 40*s*.

Mr. J. H. CAPES, superintendent of the attendance officers in the Education Department, Leeds, gave evidence as to the certificates in question.

CHARLTON FORMAN was another witness. He stated that he attended patients for Mr. Lyddon and that Mr. Lyddon did very little of the work. He (Forman) signed certificates.

Mr. LYDDON, on being called upon by the President to cross-examine the witness, said that he had given his attention to the practice.

The PRESIDENT asked Mr. Lyddon to put questions to the witness.

Mr. LYDDON: Is it not the case that I have done the work but not the writing?

WITNESS: No.

Mr. BODKIN (the legal assessor): Did Mr. Lyddon give evidence before the jury that he gave you no authority to sign his name to that or any document?

WITNESS: Yes.

Did you go into the witness-box and say that he gave you authority to sign the certificate?—That is so.

Mr. BODKIN: The jury then found you had used his name without authority.

WITNESS went on to admit that he had advertised for a qualified medical man with a view to partnership. He had been an unqualified assistant. He alleged that a partnership was entered into between Mr. Lyddon and himself. The profits were to be shared. He (Forman) had attended patients, and he had discussed a good many cases with Mr. Lyddon. Mr. Lyddon sometimes did locum work, but he (Forman) did the whole work when he was away. It was the gross takings he divided with Mr. Lyddon. Mr. Lyddon was appointed medical officer to clubs.

Evidence was given with regard to the allegation that Forman signed certificates for children without Mr. Lyddon seeing them.

This concluded the case against the accused practitioner.

Mr. LYDDON addressed the Council on his own behalf. He said that he joined Forman on the understanding that he (Forman) was to be surgery attendant and dispenser. He said to Forman: "You must keep to your duties as surgery attendant." He instructed Forman on no account to do any work which he should not do. He alleged that Forman had seen patients, and had not put them on the visiting list and had signed his principal's name saying that Mr. Lyddon was absent in order to see the patients himself. He (Mr. Lyddon) had had no other practice, and he never authorised Forman to sign his name without his knowledge or consent. He never authorised him to do that unless he had seen the patient himself. He always had thought that if he did the work of seeing the patient he could pass the certificate over to other people to sign for him. It had been an error of judgment, but he had always done the work himself. He did not think that he had signed his name for upwards of 20 years. He complained that Forman had prevented him seeing patients.

The PRESIDENT: I want you to say something about your arrangement with Forman.

Mr. LYDDON said that Forman had advertised for a medical man. Forman was an unqualified man who wanted a medical man to join him and he would introduce him to patients. He (Mr. Lyddon) thought that he was to do the work and that Forman was to be purely a surgery attendant and dispenser. He went on that understanding. Forman had pushed him on one side.

The PRESIDENT: You have said nothing about the half share.

Mr. LYDDON: There was an arrangement that the profits should be divided. He was to act as surgeon, but the messages had not been given to him. He denied authorising Forman to do medical work. He pleaded guilty to not signing, but he had always done the actual work.

After deliberation *in camerâ*, the PRESIDENT, in announcing the decision of the Council, said:—Mr. Charles Lyddon: I have to inform you that the Council have judged you to have been guilty of infamous conduct in a professional respect, and have directed the Registrar to erase from the Medical Register the name of Charles Lyddon.

The Council took up the consideration of the case of James Forrest, formerly registered as of Blackburn, Lancs., afterwards as of 77, Park-lane, Croydon, and now as of 60, Gordon Mansions, Gower-street, W.C., M.B., Bac. Surg. 1897, Univ. Edin., who was summoned to appear before the Council on the following charge as formulated by the Council's solicitor:—

That you have associated yourself, as a member of its committee and also as one of its surgeons, with an institution called the "Eye and Ear Clinique," and also the "National Eye Hospital," and the "National Eye, Ear, Nose, and Throat Hospital," of 123, Oxford-street, London, W., which advertises by pamphlets and in the public press for paying patients. And that in relation thereto you have been guilty of infamous conduct in a professional respect.

Dr. Forrest appeared in answer to his notice and was accompanied by his solicitor, Mr. Washington.

The complainants, who were the British Medical Association, were represented by Mr. J. Smith Whitaker, the medical secretary of the association, who was accompanied by Mr Hempson, solicitor.

Sir William Whitla, Dr. Saundby, Dr. Dixon Mann, and Dr. Newsholme withdrew from the Council during the hearing of the case.

Mr. SMITH WHITAKER, in opening the case, said that it resembled the Birmingham Consultative Institute case which some years ago came before the Council. The Council had now before it a case in which there had been considerable advertising of the institution. Reduced fees were stated by the institution to be charged for patients who attended for treatment. In each case the reason put forward was that it was intended to meet a public need—namely, to reach a

class of the community which could not afford to pay the fees of ordinary specialists but could afford to pay the fees of the institution. It would appear that the main facts of this case were not in dispute. At 123, Oxford-street, there was the institution with which formerly another medical man and Dr. Forrest were connected, and now through the death of that medical man Dr. Forrest was himself connected. Patients were charged half a guinea for the first attendance and 5*s*. afterwards. The advertisements of the institution were inserted in the papers. The Council would see that it was described as an institution where specialists could be consulted for affections of the ear, throat, and nose. A letter from the secretary would be put in, in which it was stated that treatment was given by well-known specialists, Dr. —— and Dr. Forrest. The question which he had to submit to the Council was whether practitioners should be allowed, by surrounding themselves by the paraphernalia of an institution and a committee, to advertise themselves in a way not permitted to ordinary practitioners. Dr. Forrest admitted that he was associated with the institution. He admitted that it was advertised in the lay press, but he denied that he had been guilty of infamous conduct in a professional respect. He brought forward a Sunday paper in which appeared the advertisements of other hospitals which were inserted with the object of getting paying patients. Dr. Forrest pointed out that these had appeared regularly for years and the Council had taken no action. On that part of the defence he (Mr. Smith Whitaker) would submit that the Council did not take the initiative in prosecuting members of the medical profession except in cases brought forward by public bodies. The Council judged each case on its merits, and it had not before it the facts to say whether other institutions were similar to this case. The institutions which were adduced were well-known institutions for the treatment of persons who were believed to be fit recipients of charity. He submitted that there were differences between them and the institution with which this case was concerned.

Mr. GEORGE THOMAS COOPER gave evidence with regard to advertisements and a pamphlet concerning the institution in question.

Mr. T. W. TYRRELL, clerk to Mr. Hempson, gave evidence with regard to a visit he paid to the clinique, where he saw Dr. Forrest in respect to his eyesight.

Cross-examined by Mr. WASHINGTON, WITNESS admitted that he went to the institution for the purpose of getting information for the inquiry. He did not give his real name. He found a copy of THE LANCET on the table there, and his name had been in it a few weeks before. He did not want Dr. Forrest to know his name.

This concluded the complainants' case.

Dr. JAMES FORREST then gave evidence on his own behalf. He stated that he had been connected with the institution for some three years. He had previously had considerable experience in diseases of the throat, eye, and ear, and he had held posts in hospitals in London and had studied in Vienna and Berlin. He had formerly had a general practice in Blackburn. He had been practising for nearly 13 years. He was one of the surgeons of this clinique. It was governed by a committee, and up to the present he had received no remuneration at all. It was intended for persons who could not pay the high fees of Harley-street. It was not established for profit at all. The pamphlets were given to nobody except patients and persons who applied for them. The first advertisement that was sent out was not brought under his observation but was sent out by the secretary without being shown to him. The committee decided to advertise in the press, in a great part owing to the proceedings of other hospitals. The secretary was told to advertise in the press stating the objects of the institution.

To your surprise an advertisement appeared?—The medical men took exception to the nature of the advertisement. The other advertisements contained merely the statement of the facts.

Were you guided in your advertising by the fact that the other hospitals were advertising in all the Sunday papers?—It was that fact that determined us to do so.

You came to the conclusion from these advertisements that you were not guilty of any infamous conduct in allowing advertisements to go to the press?—Yes. Our knowledge was that the revenue of these hospitals was derived from paying patients.

Are you prepared to advise your committee not to advertise if the Council says that it is wrong?—Of course. If it is wrong, I am bound to do so.

Dr. FORREST went on to say that it was desired to give publicity to the clinique. Dr. —— and himself were against advertising in a continuous manner as was done by other hospitals.

If the Council considers that you are wrong in allowing advertising of the clinique, you are perfectly prepared to give it up, provided the same measure is meted out to you as to other people?—Yes.

Cross-examined by Mr. SMITH WHITAKER, WITNESS admitted that he was a member of the committee of the institution and accepted a certain responsibility for what was done. The object of the pamphlet was to make the institution well known.

You said that you were willing to conform to any pronouncement of the Council if other hospitals were made to do the same?—Yes.

Why do you attach any condition of that kind?—Merely because it is right that what would be right for them would be right for us.

That would be for the Council?—Certainly.

WITNESS said that it was desired to gain publicity for the institution, because it was wished that it should be self-supporting.

You want a sufficient number of people to pay the half-guinea fees?—The object of the institution is to be self-supporting.

Re-examined by Mr. WASHINGTON, Dr. FORREST said that an in-patients' department had been practically decided upon. The institution was not self-supporting. He had not received any payment and he would not receive any honorarium of £150 until after the revenue exceeded the expenditure. That stage had not been arrived at.

In answer to Mr. BODKIN, Dr. FORREST stated that he took no part in forming the clinique. He had not said to Mr. Tyrrell that he wanted to get known.

In reply to the PRESIDENT, WITNESS said that the money received in fees went on the upkeep of the institution. That expenditure was on rooms and current expenses. He did other consulting work in London and Croydon. The quorum of the committee of management of the clinique was five. He mentioned their names, including that of Mr. Yates, who had given a guarantee. He did not know whether this gentleman took an interest in any other hospital.

Mr. WASHINGTON said that if the Council was of opinion that there was any doubt as to their being a *bonâ-fide* committee it was his and not Dr. Forrest's fault that they were not present. If an adjournment were given he might be able to bring some of the committee before the Council, and the books would be open to inspection.

The PRESIDENT, after consultation with the members of the Council, granted an adjournment of the case until the following day to enable further evidence to be brought.

The Education Committee.

Dr. MACKAY, chairman of the Education Committee, informed the Council that the committee was not prepared to present a report during the present session.

Examination for the Services.

A report by the Examination Committee on the returns as to examinations for the Services was received.

The Apothecaries' Society of London.

On the motion of Mr. NORTON it was agreed that Mr. H. S. Pendlebury, F.R.C.S., should be appointed assistant examiner in surgery to the Apothecaries' Society of London, *vice* Mr. Stonham, who retired by rotation.

Report of Public Health Committee.

Sir JOHN MOORE moved that the report of the Public Health Committee should be received and the recommendation therein contained adopted.

The report was in the following terms:—

It will be remembered that in the last report of the Public Health Committee, dated May 25th, 1909, a correspondence with the India Office was considered in regard to the recognition of the ten new divisions into which India had been divided for purposes of sanitation, and that in the course of this correspondence it was pointed out that two of the districts, Peshawar and Quetta, were below the approved standard of 30,000 civil population.

In December, 1909, the War Office resumed the subject, explaining that at the time of the former application the figures for the total civil population were not available, but that the actual totals since obtained raised the population of Quetta to 25,114, and that of Peshawar to

37,160. Quetta being still below the proper standard the Army Council explained that they did not now seek any amendment of the Council's rules in regard to this division, but they would be glad to have the other nine divisions recognised.

After correspondence with Sir William Power, then chairman of the Public Health Committee, and the President, it was thought to be the best course to inform the War Office that the chairman of the Public Health Committee was of opinion that the Council would approve the list, including Peshawar but excluding Quetta, but that there would be no meeting of the Council until May. Meanwhile, if any particular applicant wrote to the Council (with reference to his admission to examination for the D.P.H. by one of the licensing bodies) to know whether any particular Indian command was recognised, the case should be dealt with specially as an exceptional one.

No special application of this sort has been received, and it remains for the Council now to definitely decide as to the recognition.

The committee made the following recommendation :—

That, in view of the information furnished by the War Office in reference to the standing of the divisional sanitary officers in India and the existing populations of the following nine of the ten divisions into which India has recently been divided for purposes of sanitation—namely, Peshawar, Rawalpindi, Lahore, Mhow, Poona, Meerut, Lucknow, Secunderabad, and Burma, these said nine divisions be recognised under Rule 3 (*f*) of the rules and regulations of the General Medical Council for diplomas in Public Health.

Dr. NORMAN MOORE seconded and the motion was agreed to.

The Council adjourned.

FRIDAY, MAY 27TH.

The Council resumed its sittings to-day. Sir DONALD MACALISTER, the President, was in the chair.

Penal Cases.

The Council took up the consideration of penal cases. It first considered the report of the Dental Committee on the charge against Ernest Horne, in regard to whom the Dental Committee had found the following facts :—

The complaint against Ernest Horne of advertising his practice having been referred to the Dental Committee to ascertain the facts, the Dental Committee beg to report as follows: The case was considered by the Dental Committee on Nov. 22nd, 1909. Mr. Horne gave evidence on his own behalf, admitting that he had used certain cards in connexion with his practice by way of advertisement, but in the course of his evidence the fact was elicited that he was carrying on a branch practice at Saxmundham, Suffolk, by an unregistered assistant who did the whole work except operations performed under anæsthetics, which Mr. Horne stated that he always performed himself. The committee thereupon, without finding the facts, postponed the inquiry into the charge in order that Mr. Horne might be able to add to the evidence he had given some more satisfactory assurance, not only as regards the practice of advertising, but also as regards the matters stated by himself in evidence aforesaid.

The case was further considered by the Dental Committee on May 23rd, 1910. The committee find that the following facts were established by the evidence: The said Ernest Horne was registered in the Dentists Register on December 9th, 1878, as "In practice before July 22nd, 1878," and his address in the Register for the current year is Gildencroft, London-road, Lowestoft, N. The said Ernest Horne has advertised his professional practice by exhibiting cards containing statements claiming the use in the painless extraction of teeth of a wonderful preparation of his own and comparing this with common fluids used by some; also containing a comparison of the fees charged by him with those charged by other dentists. The said Ernest Horne has also carried on his branch practice at Saxmundham by means of an unregistered assistant, whom he has knowingly permitted and employed to perform operations in dental surgery. The said Ernest Horne states that he has discontinued all advertising and has discharged the unqualified assistant at Saxmundham, and he gave the committee his undertaking that he will not in future advertise or employ any unqualified assistant in the carrying on of his dental practice.

Mr. HORNE attended and repeated to the Council the undertaking which he had given to the committee.

The PRESIDENT, in announcing the decision of the Council, said: Mr. Ernest Horne, the Council have considered the report of the Dental Committee and the assurances which you have given as to advertising and the employment of unqualified assistants in the future, and have authorised me to inform you that they have not directed the Registrar to erase your name from the Dentists Register.

The Council then considered the report of the Dental Committee on the charge against Thomas Abraham Rogers. The committee found that the following facts were established by evidence :—

The said Thomas Abraham Rogers was registered in the Dentists Register on August 29th, 1878, as "In practice before July 22nd, 1878." His address in the Register for 1910 is 258, Caledonian-road, London, N. The said Thomas Abraham Rogers has habitually permitted an unqualified person named Merton to attend patients and perform dental operations upon them and to practise dentistry on his behalf and in his name at 41, High-street, Watford, 17, High-street, Hemel Hempstead, and High-street, Berkhamsted, all in the county of Herts. The said Thomas Abraham Rogers has also widely advertised his professional practice by various objectionable methods, viz.: (*a*) By the issue and circulation of a card containing laudatory statements as to his own skill and methods and claims of superiority over other practitioners. (*b*) By advertisements in the public press, also containing laudatory statements as to his own skill and methods.

Mr. Rogers did not attend, but wrote that his practice had been sold to Mr. Merton.

The PRESIDENT, in announcing the decision of the Council, said: I have to announce that on the facts found in the report of the Dental Committee the Council have judged Thomas Abraham Rogers to have been guilty of infamous or disgraceful conduct in a professional respect, and have directed the Registrar to erase from the Dentists Register the name of Thomas Abraham Rogers.

The Council considered a report of the Dental Committee on the charge against Mr. Edward Joseph Regan. The committee found that the following facts were established by the evidence :—

The said Edward Joseph Regan was registered in the Dentists Register on July 11th, 1879, as "In practice before July 22nd, 1878." His address in the Register for 1910 is 7, College-terrace, Swiss Cottage, London, N.W.

1. The said Edward Joseph Regan has permitted an unqualified person named Louis Dupan to practise in his name or in succession to him as a dentist on premises belonging to him at 5, Stretford-road, Manchester; that he thereby enabled the said Louis Dupan to practise as if he were qualified and to advertise such practice by the use of the name of the said Edward Joseph Regan in connexion therewith in a circular or pamphlet issued by the said Louis Dupan, and containing laudatory statements as to the skill and methods of the said Edward Joseph Regan.

2. The said Edward Joseph Regan has advertised his professional practice at 21, College-crescent, London, N.W., by the issue of a pamphlet or circular of an objectionable character and containing statements implying praise of his own skill and methods.

The solicitor representing the said Edward Joseph Regan made a statement on his behalf, but called no evidence, and stated that the said Edward Joseph Regan left the matter in the hands of the committee. He declined a suggestion made by the committee to adjourn the inquiry for the attendance of his client.

The complainants were the British Dental Association, who were represented by Mr. R. W. TURNER.

Mr. REGAN attended and explained to the Council that he had left Manchester for five years, and the man who was carrying on the business there was doing it in his own name. He argued that it was therefore impossible to charge him with covering. He regretted the circular. He was willing to conform to the rules of the General Medical Council as far as it was within his power. He had always endeavoured to do so. If he had committed an offence it was in ignorance. He could only express his regret. He was prepared to give an undertaking that this would not occur again, and he would not offend in future.

The PRESIDENT, in announcing the decision of the Council, said: Mr. Regan, the Council have considered the facts proved in the report of the Dental Committee but have not proceeded to pronounce judgment in your case, and have postponed the further hearing of your case till the November session, when you will be required to produce evidence as to your professional conduct in the interval, with special reference to your having ceased all relations with unqualified practitioners and advertising.

The Council took up the consideration of a report of the Dental Committee on an entry in the Dentists Register. The report ran as follows :—

The Dental Committee have held an inquiry, in pursuance of the powers conferred upon them by the Dentists Act of 1878, for the purpose of ascertaining whether the person registered in the Dentists Register with the name and particulars as follows :—

Name.	Address.	Date of registration.	Description and date of qualification.
George Norman.	25, The Grove, Hammersmith, London, W.	1878, Oct. 15th.	In practice before July 22nd, 1878,

is deceased, and whether the said entry has been correctly made or fraudulently caused to be made in the said Register and should be erased therefrom.

The Committee find that the following facts were established by the evidence :—

1. The person registered in the Dentists Register as George Norman as aforesaid is deceased. 2. The person now practising as a dentist at 25, The Grove, Hammersmith, aforesaid, is not the George Norman who was registered on Oct. 15th, 1878. 3. The said registration has been continued or maintained up to the present time by replies to inquiries purporting to be signed, but not in fact signed, by the said George Norman.

The PRESIDENT pointed out that there was no person accused.

After deliberation *in camerâ*

The PRESIDENT said: I have to announce the decision of

the Council as follows: That it having been established as a fact proved in the Report of the Dental Committee that the person originally registered as George Norman is deceased, the Registrar has been directed to erase his name from the Dentists Register.

The next case to be considered was one adjourned from Nov. 25th, 1909, and concerned Robert Orr, registered as of Ceres, Fifeshire, M.B., Bac. Surg. 1901, Univ. Glasg., who had been summoned to appear before the Council on the following charge as formulated by the Council's solicitor:—

That you were on Oct. 1st, 1907, convicted at the Sheriff Court of Fife at Cupar of the following offence, namely, of assaulting a constable of the Fifeshire Constabulary while engaged in the execution of his duty. And that you were on July 6th, 1909, convicted of the following offence, namely, of breach of the peace and of assaulting James Arthur, Helen White or Arthur, Catherine Dempsey or Kerr, and Catherine Quin.

On Nov. 25th, 1909, the PRESIDENT announced the decision of the Council as follows:—Mr. Orr, The Council has given careful consideration to the question of your convictions and the circumstances connected therewith, and has decided to postpone judgment thereon till the May session, when you will be required to be present, and it will be in your interest to produce on that occasion testimony from persons of position in your own neighbourhood as to your character and conduct in the interval.

Dr. ORR appeared and handed in several letters from persons of position in his neighbourhood who testified to his satisfactory conduct and to his popularity. His election to serve on local bodies was also mentioned.

Dr. ORR briefly expressed his deep grief at his conduct on the occasions referred to in the complaint. He gave the Council an assurance that if the matter was overlooked on this occasion he would do his utmost to be more careful in the future. The case had caused him a great deal of mental worry.

The PRESIDENT announced the decision of the Council in the following terms:—Mr. Orr, I have to announce to you that the Council have considered again the fact of your conviction, as also the certificates which you have tendered, and have not directed the Registrar to erase your name from the Medical Register; but they have authorised me to give you a solemn warning as to the habit which has led to this conviction, and to inform you that should any future conviction in regard to you be reported to the Council they would take a much more serious view of the case than they have taken on the present occasion.

The next case to be considered was that (adjourned from Nov. 26th, 1909) of Charles Frederick Dillon Shaw-Mackenzie, registered as c/o Messrs. Duncan & Duncan, solicitors, Dingwall, M.B., Mast. Surg. 1885, Univ. Edin., who had been summoned to appear before the Council on the following charge as formulated by the Council's solicitor:—

That you were on February 8, 1908, convicted of the following misdemeanour at the petty sessions at Whitby, in the county of York—namely, of being unlawfully guilty, while drunk, of disorderly behaviour at Ruswarp.

And that you were on January 25, 1909, convicted of the following misdemeanour at the petty sessions at Wigton, in the county of Cumberland—namely, of being drunk and incapable in Eden-street, Silloth.

On Nov. 26th, 1909, the PRESIDENT announced the decision of the Council as follows:—"I have to announce that the Council has found that Mr. Charles Frederick Dillon Shaw-Mackenzie has been proved to have been convicted of the misdemeanours alleged against him in the notice of inquiry, and that the Council has decided to postpone judgment thereon till the May session, when he will be required to be present, and to produce on that occasion testimony from persons of position as to his character and conduct in the interval."

Mr. Shaw-Mackenzie did not appear.

After deliberation on the case *in camerâ*,

The PRESIDENT said: I have to announce that Charles Frederick Dillon Shaw-Mackenzie, having been proved to have been convicted of divers misdemeanours alleged against him in the notice of inquiry, the Council have directed the Registrar to erase from the Medical Register the name of Charles Frederick Dillon Shaw-Mackenzie.

The Council considered the case of Jean Leon Louis, registered as of 40, Castlereagh-street, New Silksworth, near Sunderland, M.B., Bac. Surg. 1899, Univ. Edin., who was summoned to appear before the Council on the following charge as formulated by the Council's solicitor:—

That you were at the Durham Assizes, held on November 8, 1909, convicted of publishing a defamatory libel of and concerning Elizabeth Ann Pollard and Jane Pollard, and ordered to enter into your own recognisances with one surety to be of good behaviour and to come up for judgment if called upon and to pay all costs of prosecution.

Mr. Louis attended and letters were read from him and his solicitor explaining the circumstances of the conviction.

The Council having deliberated *in camerâ*,

The PRESIDENT said: Mr. Louis, I have to announce to you that it having been proved that you have been convicted of the misdemeanour alleged against you in the notice of inquiry, the Registrar has been directed to erase your name from the Medical Register.

The Council then resumed consideration of the case of James Forrest, which had been adjourned on the previous day.

Dr. Forrest's name was called but he did not appear, nor was he on this occasion represented by a legal adviser.

Mr. WINTERBOTHAM, the Council's solicitor, stated that a letter, signed "James Forrest," had been received by the Registrar. It ran:—

Re Eye and Ear Clinique.

Owing to the interval of adjournment being so brief, I find it impossible to secure the attendance of any of the committee to-morrow afternoon at four o'clock. Under these circumstances I tender to the Council my resignation of my registration and beg that they direct my name to be erased from the Medical Register. I may state, whatever the verdict of the Council may be with regard to my association with the Eye and Ear Clinique, I have determined to have my name expunged from the Register partly as a protest against the anomalous methods of the British Medical Association, and partly owing to the conviction that the diagnosis and treatment of ophthalmic, nasal, and aural affections will in the near future be undertaken by a distinct body of men in the same manner as the treatment of dental affections has been.

Mr. SMITH WHITAKER, in addressing the Council on behalf of the complainants, said that it had had evidence of the connexion between Dr. Forrest and the Eye and Ear Clinique. From that evidence he submitted that Dr. Forrest took a large part in the management of that institution and was responsible to a large extent for the advertising. He further submitted that a medical practitioner should not be allowed to associate himself with such an institution.

The Council deliberated for about three-quarters of an hour *in camerâ*.

When the public was readmitted,

The PRESIDENT said: I have to announce that the case against James Forrest is adjourned to the November session in order to enable him to bring further evidence in answer to the charge.

The next case was that of William Gordon Hanna, registered as of Pleck House, Whalley-road, Accrington, M.D. Q.Univ.Irel. 1880, Lic. Midwif. K.Q. Coll. Phys. Irel. 1883, Lic. R. Coll. Surg. Edin. 1899, who was summoned to appear before the Council on the following charge as formulated by the Council's solicitor:—

That you were on Feb. 1st, 1910, convicted at the Manchester Assizes of feloniously using an instrument with intent to procure miscarriage and sentenced to five years' penal servitude.

Dr. Hanna did not appear.

Mr. WINTERBOTHAM mentioned to the Council that the jury, when the case was tried on the first occasion, disagreed. The verdict was given on a second hearing.

The PRESIDENT said: I have to announce that William Gordon Hanna having been proved to have been convicted of a felony, the Registrar has been directed to erase his name from the Medical Register.

The last case to be considered was that of Donald Murdoch, registered as of 28, Delancey-street, Camden Town, N.W., Lic. Soc. Apoth. Lond. 1871, Mem. R. Coll. Surg. Eng. 1872, who was summoned to appear before the Council on the following charge as formulated by the Council's solicitor:—

That you were convicted on Jan. 1st, 1910, at the Clerkenwell police-court of being drunk and disorderly, and sentenced to one month's imprisonment with hard labour.

That you were also convicted on April 28th, 1910, at the Bow-street police-court of being drunk, and fined 10*s*.

That you have been four times previously convicted, of which the following are the particulars:—

Date of conviction.	Offence.	Conviction.
Jan. 2nd, 1908 ...	Drunk ...	Fined 5*s*. or 1 day's imprisonment.
March 5th ,, ...	,, ...	Fined 21*s*. or 14 days' imprisonment.
Jan. 19th, 1909 ...	,, ...	Fined 20*s*. or 7 days' imprisonment.
July 30th ,, ...	Drunk and disorderly.	14 days' imprisonment with hard labour.

Mr. Murdoch did not appear, but a communication from him was read.

The PRESIDENT said: I have to announce that Donald Murdoch having been proved to have been convicted of the divers misdemeanours alleged against him in the notice of inquiry, the Registrar has been directed to erase his name from the Medical Register.

The Council adjourned.

SATURDAY, MAY 28TH.

The Council resumed its sittings to-day. Sir DONALD MACALISTER, the President, was in the chair.

Apothecaries' Hall of Ireland.

Dr. MCVAIL submitted a report from the Examination Committee on the Final Examination of the Apothecaries' Hall, Dublin. The report was in the following terms:—

The assistant examiners report their satisfaction with the examination of the Apothecaries' Hall, Dublin, held in April, 1910. The assistant examiners state that in the written examination in medicine five questions had to be answered, and that the time allowed was 1½ hours; that in the surgical paper five questions had to be answered, and the time allowed was 1½ hours; and that in midwifery, with gynæcology, five questions had to be answered, and the time allowed was 1½ hours. The Examination Committee recommends that the attention of the Apothecaries' Hall should be directed to the recommendation of the Medical Council that, on an average, half an hour should be allowed for each written question.

The report having been received,

Dr. MCVAIL moved that the recommendation of the Examination Committee should be adopted by the Council.

Dr. DIXON MANN seconded.

Dr. ADYE-CURRAN suggested that it would be only right that the recommendation should be sent to other licensing bodies.

Dr. MC. VAIL remarked that a recommendation in these terms had been made to all the licensing bodies, and was reaffirmed when the report on the cycle of examinations was before the Council.

The motion was agreed to.

The Final Examination.

Dr. MCVAIL presented to the Council a memorandum from the Examination Committee on the question of allowing candidates to enter for each of the subjects separately of the Final Examination in medicine, surgery, and midwifery. After the resolution of the Council which remitted the consideration of this subject to the Examination Committee, it became necessary to ascertain what the practice of each of the licensing bodies at present was. The memorandum now submitted showed what the practice was, as far as had been ascertained from calendars and published regulations. One set of bodies allowed medicine, surgery, and midwifery to be entered for separately. Other bodies did not permit those subjects to be entered for separately but might require re-examination only in subjects or groups of subjects in which the candidate had failed. A third set of bodies required the three subjects of medicine, surgery, and midwifery to be taken and passed together. Two of the new universities had not yet supplied the information. The Examination Committee had an observation to make. It had to consider whether it would advise the Council to recommend uniformity of action on the part of the various examining boards, such uniformity to consist of the exclusion of all subjects from the Final Examination excepting the three great subjects of medicine, surgery, and midwifery, and further whether the Council should recommend that these three subjects should be all passed at the same examination, failure in one to cause failure in all. The question was a very big one. He moved that the licensing bodies should be acquainted with the memorandum and should be invited to express their opinion on the subject with which it dealt.

Sir C. NIXON seconded.

Dr. MORMAN MOORE said that he did not understand why the Council should again wish to refer this question to the qualifying bodies except that it was a good thing to acquaint them with what was going on in the Council. The Council had not power to compel them to take the subjects separately or together. There was a great deal to be said on both sides. He was inclined to the view that it would encourage thorough study in the student to let him take the subjects separately. It was more likely he would observe cases thoroughly if he had not the examination in the whole three subjects hanging over his head at once. The object of the Council was that practitioners should know as much as possible of their profession when they were enrolled on the Register.

Dr. FINLAY remarked that he would like to see the matter go to the bodies for consideration. He recognised that it was quite true that this was only a question of recommendation on the part of the Council.

Sir C. BALL said that he was anxious that the licensing bodies should have an opportunity of seeing in a collected form what was the practice of every licensing body in the country. Each of them had formed different ideas as to what was the best method of procedure for the Final Examination.

Dr. TAYLOR mentioned that in the University of London medicine was grouped with subsidiary studies. Surgery and midwifery were put together.

Sir C. NIXON said that in the National University of Ireland it was now required that the candidates should present themselves for the three subjects of medicine, surgery, and midwifery at one time. If a candidate passed exceptionally well in two of the subjects and failed in the third, he was allowed to present himself separately for the third.

Dr. NORMAN MOORE remarked that if the Council could get an answer from the licensing bodies in a year it would be in ample time.

The PRESIDENT said that it might be suggested that it should be sent by the end of the year. That would be mentioned in the letter of the Registrar to them.

The motion was agreed to.

Instruction in Ophthalmology, Otology, and Diseases of the Throat.

The following report was received from the Examination Committee:—

That the Examination Committee is of opinion that the Council should recommend to the licensing authorities that there be instruction in ophthalmology, otology, and diseases of the throat, and that every candidate be examined practically in these subjects, and that this resolution should be reported to the General Council.

Dr. MACKAY remarked that the report was a very comprehensive one. It might be carried further. There were, for example, several subjects, such as diseases of the skin and diseases of women and children, all of which were important. If the report was to be considered by the Education Committee it could not be done full justice to this year. It might be advisable that the Examination Committee and the Education Committee should discuss this matter together.

Dr. KIDD moved that the subject should be referred to the Education Committee for consideration.

Sir C. BALL seconded.

The PRESIDENT: The two committees could have a joint meeting if they think fit.

Dr. SAUNDBY: The only objection I have is that they have no time to consider the matter.

The PRESIDENT: The motion then will be a pious expression of opinion.

The motion was agreed to.

Dental Education and Examination.

Mr. TOMES submitted the report of the Dental Education and Examination Committee. It contained a letter from the secretary of the Royal College of Surgeons of England in reference to the recommendation of the General Medical Council to the effect that "one year *bonâ-fide* apprenticeship with a registered dental practitioner, after being registered as a dental student, may be counted as one of the four years of professional study." The committee did not see any necessity for advising the Council to make any change in its recommendations. The report also stated that it was desirable that a cycle of inspection of the examinations for the granting of dental qualifications should be commenced, and recommended that this should be done.

Mr. TOMES, in explaining the main features of the report, mentioned that a considerable number of dental licensing bodies had been established since the last cycle of inspection. There had been no inspection of the examinations for diplomas in dental subjects since 1897. The Dental Fund was in a satisfactory condition at present. The expense of inspection falling on that fund, the committee had no hesitation in recommending that the inspection should be commenced.

The report was received and adopted.

A motion was then agreed to that the inspection of the examinations of the various bodies granting dental qualifications should be commenced and that the Executive Committee should make arrangements to carry it into effect.

The Pharmacopœia.

The Pharmacopœia Committee reported to the Council as follows:—

From November 22, 1909, to May 23, 1910, the number of copies of the British Pharmacopœia (1898) sold by the publishers was 549. The total number of copies sold in the year beginning May 23, 1909, was 1127. The sale has thus been somewhat larger than in 1908–9. Up to the present time 41,915 copies of the Pharmacopœia and 4470 copies of the Indian and Colonial Addendum have been sold. The stock now in hand consists of 1115 copies of the Pharmacopœia, together with 1864 copies of the Addendum. This stock will probably suffice to meet the demand during the next 12 months.

A meeting of the Conference of Members of the Committee with representatives of the pharmaceutical societies of Great Britain and of Ireland was held on May 21st, 1910. A second report from the Committee of Reference in Pharmacy was presented in manuscript, giving the results of the work done by the committee to December 16, 1909, together with recommendations on particular subjects supplementary to those contained in the similar report of 1908. The conference recommended that the Pharmacopœia Committee should print and publish the report in order that its suggestions might be submitted for professional criticism. The committee have adopted the recommendation, and copies of the print will be circulated among members of the Council and others interested, and communicated to the medical and pharmaceutical journals.

The secretary of the Committee of Reference, Professor Greenish, is of opinion that by May, 1911, his committee will be able to present a final report on the revision of the pharmaceutical sections of the Pharmacopœia.

On the motion of Dr. NORMAN MOORE, seconded by Sir JOHN MOORE, the report was received.

The Report of the Finance Committee.

Mr. TOMES submitted the report of the Finance Committee. It stated that:—

The income of the General and Branch Councils for the year ending 31st December, 1909, was £8467 5*s.* 6*d.* The expenditure during the year was £8613 11*s.* 9*d.*, and consequently there was a deficit of £146 6*s.* 3*d.* This deficit is not a serious one, especially if all the facts of the case are considered. The average excess of expenditure over income during the past seven years has been £163 5*s.* 2*d*, but this includes a deficit of over £2000 in 1903. If the figures for the past five years are examined it will be found that from 1905 to 1907 there was an excess of income of £2043; while in 1908 and 1909 there was a total deficit of £802. That is to say, on balance there has been an average excess of income during the last five years of about £250. This is a matter on which the Council may fairly be congratulated, for not only has the penal work been exceptionally heavy, but the Council Chamber has been enlarged and the Press Gallery built entirely out of income. In addition to this there have been added to the Council representatives from the Universities of Liverpool, Leeds, and Sheffield, though the fees of the representative from Sheffield are not at present paid by the Council.

The committee cannot look forward to the future entirely without anxiety. The chief item of expenditure is the cost of the two annual meetings, and especially of the penal work. Moreover, the Council is continually increasing in numbers; in the last ten years four new members have been added through the creation of new universities; members will shortly be added from the Universities of Bristol and Wales and the University of Belfast, while the Council will have an additional Direct Representative. It is true that at present the fees of all these representatives do not have to be paid by the Council, but the Council will have to pay them eventually, and each member costs from £50 to £120 annually, according to the distance of his residence from London.

In moving that the report should be received and entered in the minutes, Mr. TOMES said that the multiplication of medical schools and of licensing bodies showed no signs of ceasing, but there was no sign of increase in the number of students preparing to enter the profession. Every new licensing body sought and generally obtained powers to send a representative to the General Medical Council. Every new member entailed an increase in the expenditure of the Council. The committee had in view the addition of several more members to the Council, and he would like to ask the President to use his influence to induce the new bodies who obtained representation on the Council to do as the University of Sheffield did, and to bear the cost of sending a representative until such time as the licensing body had a respectable number of graduates enrolled on the Register.

Sir HENRY MORRIS seconded.

The PRESIDENT said that the provision in the University of Sheffield Act had been adopted in the University of Bristol Act. No Act had yet been passed for a University of Wales, but it was likely that some similar provision would be inserted in it.

The motion was agreed to.

It was also decided on the recommendation of the committee that if it became necessary a grant of £150 would be made towards the expenses of the Irish Branch Council from the funds of the General Council.

Ireland and the Midwives Act.

Dr. LITTLE moved that the Council should enter in its minutes a resolution which the Irish Branch Council had passed to the effect that in its opinion it was advisable that the general provisions of the Midwives Act should be made applicable and extended to Ireland. The Irish Branch Council felt it unfortunate that midwives in Ireland should be excluded from the Midwives Act, and thought that an expression of its opinion should be forwarded to the Privy Council.

Sir JOHN MOORE seconded the motion, which was agreed to.

The Council requested the President to convey the resolution of the Irish Branch to the Lord President of the Council.

Students' Registration.

The report of the Students' Registration Committee was received.

Preliminary Medical Scientific Studies.

The PRESIDENT stated that a memorial bearing on the position of chemistry, physics, botany, and zoology in the medical curriculum had been received. It was as follows:—

MEMORIAL TO THE GENERAL MEDICAL COUNCIL.

The position of the purely scientific subjects of chemistry, physics, botany, and zoology, in the medical curriculum being one of the questions at present before the General Medical Council, we would beg to submit the following expression of our views.

The proposal to relegate the teaching of these subjects wholly to the school period appears to us a retrograde step, and one which is calculated to have a most prejudicial effect on medical education. The object of these sciences in a medical curriculum is to ensure a real scientific training for the student, to form a basis for the study of physiology, materia medica, and medicine, and to inculcate scientific method which he can apply to his purely professional studies. Were a parrot-like knowledge of the mere facts and formulæ of science all that is desired the committing of these to memory might be done at school, but knowledge thus obtained is of little practical and no educational value.

There are two chief reasons against relegating the scientific subjects wholly to school life. 1. Interference with general education. 2. It would prevent that specialisation of the scientific teaching, in the direction of a student's future medical studies, which is so desirable.

1. To acquire a scientific training of real value it is necessary that the student devote his whole energy to the subject in question. This is manifestly impossible when the preliminary examination in general knowledge is impending. Either the professional subjects or the general education must suffer. The methods of teaching best adapted to give the desired result—a true scientific training—are quite distinct from those suited to the school, and further, the power of grasping scientific generalisations is seldom developed till a later stage than that at which the preliminary examination should be passed.

2. The whole tendency just now, and a very praiseworthy one, is to specialise the preliminary medical scientific studies in the direction of the purely medical studies. The University of London, for example, has quite recently revised its syllabus for medical students in this direction by including branches of the subject which one might properly term physiological physics. Every day sees some further advance in scientific medicine; the increasing use of electricity, ionic treatment, the X rays, Finsen rays, high frequency, radium rays, &c. The physiological changes in the body are largely chemical, and synthetic compounds are being increasingly used. Medicine is thus depending more and more on organic chemistry both for methods of diagnosis and treatment. The present courses in physics, chemistry, botany, and zoology are arranged for medical students, and this applied science cannot be taught to schoolboys during school life by teachers not connected with medical study. What should be aimed at by those who care for the proper training of the student and the consequent status of the profession is a knowledge of scientific principles, especially in their application to physiology and medicine. In our opinion, therefore, no graver mistake could be made than that the General Medical Council should agree to the relegation of those subjects wholly to the school period.

PETER BENNETT, Professor of Physics, Anderson's College, Glasgow.
FREDERICK D. BOWER, D.Sc., F.R.S., Professor of Botany, University, Glasgow.
T. W. DRINKWATER, F.R.S.E., F.I.C., Lecturer on Chemistry, Surgeons' Hall, Edinburgh.
J. COSSAR EWART, M.D., F.R.S., Professor of Zoology, University, Edinburgh.
PATRICK GEDDES, F.R.S.E., Professor of Botany, Dundee.
F. R. JAPP, LL.D., F.R.S., Professor of Chemistry, Aberdeen.
CARGILL G. KNOTT, D.Sc., F.R.S.E., Lecturer on Medical Physics, University, Edinburgh.
MALCOLM LAURIE, B.A., D.Sc., Lecturer on Biology, Surgeons' Hall, Edinburgh.
W. C. M'INTOSH, M.D., F.R.S., Professor of Zoology, St. Andrews.
J. ARTHUR THOMSON, M.A., Professor of Zoology, Aberdeen.
GEORGE BELL TODD, M.B., Professor of Zoology, Anderson's College, Glasgow.
DAWSON TURNER, B.A., M.D., F.R.S.E., Lecturer on Medical Physics, Edinburgh.
JAMES G. MACGREGOR, D.Sc., LL.D., Professor of Natural Philosophy, University, Edinburgh.
J. ROBERTSON WATSON, M.A., Professor of Chemistry, Anderson's College, Glasgow.
I. BAILEY BALFOUR, M.D., Professor of Botany, University, Edinburgh.
L. A. L. KING, M.A., Professor of Zoology, St. Mungo's College, Glasgow.

Sir HENRY MORRIS remarked that the memorial contained very material errors and expressions of opinion which certainly could not be supported by a good many people who knew the state of things. He would not say that it was grossly inaccurate, but those who knew the statistics knew that it was inaccurate. It need not have been printed, for

it reproduced passages from documents which were entered in the Council's minutes in 1901 and 1902. He wanted to point out the fact that some of the statements as to the result of the school education were emphatically and absolutely wrong. However, he would move that the memorial should be received and entered in the minutes.

Dr. NORMAN MOORE seconded, and this was agreed to.

Dr. SAUNDBY moved that the memorial should be referred to the Education Committee. It would seem discourteous not to take some such step in the matter.

Sir THOMAS FRASER seconded.

Dr. NORMAN WALKER said that he was somewhat in favour of much that had been said by Sir Henry Morris. He thought that the very respectable list of signatories at the end might convey a wrong impression. There were 20 teachers of the subjects to which the memorial related in the Scottish universities. Only eight of them appeared as signatories to this document. He noticed that the signature of the professor of chemistry in the University of Edinburgh was absent from the list, but he had no doubt that he was asked for it.

The PRESIDENT remarked that there were several distinguished Scotchmen on the Education Committee and they would be able to weigh what Dr. Walker had said.

The motion was agreed to.

Reappointment of Registrar.

On the motion of Dr. NORMAN MOORE, Mr. H. E. Allen was reappointed Registrar.

A vote of thanks was passed to the President, and the Council, having concluded all the business of the session, rose. It will meet again in November.

THE REVISION OF THE MEDICAL REGISTER.

The report mentioned last week as having been presented by the Registrar to the Council had many interesting features. It mentions that in the first instance in connexion with the revision the total number of communications sent out from London was 32,720, and from the Irish Office, 4610, making together 37,330. The difference between this number and the total of those on the Register (40,257) was accounted for by the fact that inquiries were not sent to those whose names appeared as belonging to the Navy, Army, or Indian Medical Services, the lists of which had been carefully revised previously. The report proceeds to state that—

By Section XIV. of the Medical Act, 1858, the Registrars are authorised to remove names from the Register if no answer be returned to their inquiries, but this power has hitherto not been exercised until other efforts to communicate with the practitioners concerned have been made.

In the present case it was decided that a second inquiry should be sent to all those who had not replied by the end of April, and these inquiries, which in the case of England and Scotland numbered 4100 and in the case of Ireland numbered 822, were sent out on April 30. All these inquiries were *registered*, and the result of this proved very satisfactory, as in the majority of cases a reply was received or the letter was duly returned through the Dead Letter Office. Many practitioners in answering the registered inquiry expressed their thanks for the trouble which had been taken to give them another chance of replying.

By the end of August information had been received in regard to all names on the Register, with the exception in the case of England and Scotland of 584 names, and in the case of Ireland of 134 names. In order to make quite sure that there should be no case of hardship due to want of adequate notice, yet a third inquiry—which was also registered—was sent to all these persons. Also, without waiting in this case for the return of the letters through the Dead Letter Office, each name was hunted up in various books of reference, and if possible still another inquiry was sent.

In the end it only remained to take off reluctantly the names of those who still remained liable to erasure under Section XIV., either from the return of the inquiries through the Dead Letter Office, or from the neglect to make any reply. The number amounted to 463 English, 362 Scotch, 135 Irish; a total of 960. The revision is now complete, but it would be unduly optimistic to say that the Medical Register is now entirely correct, and this search has only emphasised the impossibility of having an absolutely correct book.

Another passage in the report reads as follows:—

The utmost that can be said is that it is believed that communication has been established directly or indirectly between the office and every person whose name is on the Register during the past 15 months. Everything that can be done by the office to make the inquiry accurate and not to inflict hardship on the individual has been done. It is feared that the revision has not been concluded without some mistakes, but, where they have been made, it has not been for want of trouble to try and prevent them; however much care in checking is taken the factor of "human error" is bound to be one which cannot be completely eliminated.

"One of the difficulties," the report proceeds, "in making the Register an exact enumeration of the qualified practitioners in the United Kingdom is the fact that it is quite possible for a practitioner to practise for many years after his name has been taken off the Register under Section XIV., the chief reason being that the Government has not seen its way to supply all officials, such as registrars of deaths, with official copies of the Register, for purposes of reference and, even when a copy is supplied, it does not appear that it is always consulted. In order that this unsatisfactory state of affairs may be brought to an end, arrangements have been made with the Registrars-General in England and Scotland to supply the superintendent registrars of deaths with copies of the Register at the Council's expense for this one year, and they have kindly undertaken to give instructions that the names of all practitioners who sign certificates during the year are to be looked up: in Ireland the circumstances are somewhat different, but the names of practitioners signing certificates will be looked up in the Register by the authorities at Dublin Castle, the Council undertaking to pay for the extra labour involved. The expense to the Council of this attempt to minimise unregistered practice will be about £330, but some of this may be recovered, and in any case it is of great importance that the provisions of the Medical Act should be carried out."

The report closes with a summary of the details of the cost, gross and net, of what has been done, showing that after deduction of the expenditure has been made for excess of fees received for extra registration there was a total net expenditure of £164 7*s*. 2*d*.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary Comitia was held on May 26th, Sir THOMAS BARLOW, Bart., K.C.V.O., the President, being in the chair.

Before commencing the formal business of the Comitia, the PRESIDENT briefly addressed the Fellows, all standing, on the loss which the College and the whole civilised world had sustained in the death of His Majesty King Edward VII. He referred to the practical interest taken by the late King in medical work and in all charitable agencies, mentioning especially his active sympathy and help in regard to cancer research, to the Hospital Fund, and the sanatorium which bears his name, and also his work in connexion with the housing of the poor. He proposed the following motions:—

1. That this College humbly approach His Majesty King George V. and express its profound sorrow at the loss which His Majesty and the Royal Family have sustained, and at the same time assure him of the loyalty and devotion of the College to his throne and person.
2. That this College humbly approach Her Majesty Queen Alexandra and express its profound sorrow at the irreparable loss she has sustained.

Draft addresses, which had previously been prepared by the College officers, were then read and approved, and the President was authorised to affix the College seal to engrossed copies of the same and to make whatever arrangements were necessary for presentation to their Majesties.

The following members elected to the Fellowship at the last meeting were admitted Fellows:—Otto Jackson Kauffmann, M.D. Lond.; Charles Hubert Roberts, M.D. Lond.; Edward Arthur Saunders, M.B. Oxon.; Francis Edward Fremantle, M.B. Oxon.; Lewis Albert Smith, M.D. Lond.; Frederick Craven Moore, M.D. Vict.; John Charlton Briscoe, M.D. Lond.; David Forsyth, M.D. Lond.; William Henry Willcox, M.D. Lond.; Arthur Frederick Hertz, M.D. Oxon.; and Conrad Meredyth Hinds Howell, M.D. Oxon.

Mr. Kekobad Cowasji Anklesaria, L.R.C.P., was admitted a Member of the College.

A communication was received from the secretary of the Royal College of Surgeons of England reporting proceedings of the Council.

A letter was read from the authorities of the Chelsea Physic Garden acknowledging the donation of 10 guineas made by the College.

The SENIOR CENSOR (Sir WILLIAM ALLCHIN) proposed, and Dr. F. DE HAVILLAND HALL seconded, the following motion:—

That the title of Emeritus Librarian be conferred on Dr. Payne.

This was carried unanimously.

On the motion of the PRESIDENT, Sir William Allchin was elected representative of the College on the Committee of Management of the Chelsea Physic Garden.

A report was received from a committee nominated on March 14th last for the purpose of replying to a letter from the Danish Legation concerning the practice of massage.

The REGISTRAR moved that the following temporary by-law be enacted for the first time:—

That Robert Dawson Rudolf, M.D. Edin., elected to the Fellowship on April 28th, being resident in Canada, be admitted *in absentiâ*, any by-law to the contrary notwithstanding.

This was agreed to.

The PRESIDENT then dissolved the Comitia.

THE LANCET.

LONDON: SATURDAY, JUNE 4, 1910.

The Revision of the Medical Register.

THE summer session of the General Medical Council, which commenced on Tuesday, May 24th, came to a conclusion on Saturday, May 28th, the various business which was laid before the Council being discharged with great expedition. By far the most important matter before the Council was the report on the Medical Register, in which the Registrar, Mr. H. E. ALLEN, described the steps which he had undertaken in 1909 for the revision of the Medical Register. Some notes on this report is printed on p. 1555 of this issue of THE LANCET. It is an open secret that some time ago, ten years or more, the Medical Register was not an accurate publication, and this was generally felt to be a very serious matter, seeing that the Register is the official roll of the profession, and that in a court of law the presence of a man's name on that roll entirely determines his professional status. We ourselves published about that date several articles calling attention to dangers which might follow upon errors in the Register, the occasion of some of our remarks being the success of certain cases of impersonation, but in all our comments we were careful to allot the bulk of the responsibility for a bad state of affairs to the proper quarter—namely, to the medical profession at large and not to the registration department of the General Medical Council. Whether as far back as 1899 or so the Council fully realised the importance of making the Register as accurate as possible, and the serious danger of allowing such a compilation in any way to fall out of date, seems perhaps a little doubtful. We remember, for example, that in 1899 we stated that we were able in a few minutes to find the names of 21 dead persons on the Medical Register—an important fact when it is recollected how wide a door is thus opened for the impersonator. In calling attention to the matter, we recognised that the fault really in the first instance must be on the side of the practitioners who did not keep the Registrar adequately informed in the matter of addresses and qualifications, but it certainly seemed to us that the General Medical Council was courting trouble in not making some drastic move towards ensuring greater accuracy of its roll. The Registrar, it is true, printed then, as he prints now, an "important notice" at the beginning of each annual issue of the Register, urging on practitioners the duty of giving immediate notice to the Branch Registrar by whom they were registered of any changes in their addresses, and the advisability of registering their full qualifications; but his words went unheeded. Moreover, dead men could not call attention to the irregularity which gave their late names a place on the Register, and it was especially in the inclusion of the names of dead men that the Register was so faulty. It seemed to us that at that time the General Medical Council was too ready to adopt a *non possumus* attitude, taking an over-full advantage of the fact that the chief blame of an inaccurate roll did not lie exactly at its door.

This attitude, if it ever existed, has now been entirely changed. The Council, with the assistance of the present Registrar, resolved during the year 1909 to take steps for a thorough revision of the Register. For some years it had been the custom to correct the Medical Register twice in five years, one of the occasions being that of the election of Direct Representatives. Notwithstanding this practice the fact that many inaccuracies existed could not be contradicted, and the general feeling grew that the time had come for an exhaustive revision, by which means only would it be possible, for example, to remove the names of many who were probably dead but about whom no authentic information had been obtained. Our abstract of Mr. ALLEN'S report gives some idea of the amount of labour that has been entailed upon the Registrar's office. No less than 37,330 inquiries were posted between the last Friday of January, 1909, and Feb. 1st, 1909, all the persons whose names were on the existing Register receiving inquiries, with the exception of members of the Navy, Army, or Indian Medical Services, full lists of whom had previously been revised in another manner. The coöperation of the press was sought, and the leading daily newspapers and medical journals of London, the provinces, and the colonies united to draw attention to the fact that the Medical Register was being drastically revised. Undoubtedly in this way the Registrar was able to get into touch with many practitioners with whom it would have been difficult to communicate from the office, even if the office had been supplied with their correct addresses. The result of the Registrar's action has been surprising. During the year the number of changes of address made in the Medical Register amounted to not less than 10,000, although it must not be inferred that all the alterations of address were necessarily changes of residence. In many cases the changes were merely trivial, due to some action on the part of postal or municipal authorities, to the addition or deletion of some special name to a residence, and so on. But leaving all this aside, the amount of correction rendered necessary by the elaborate scheme of scrutiny embarked upon proved how necessary the revision was. At the end of April, as will be seen by our abstract of the report, 4100 persons in England and Scotland and 822 in Ireland had not replied, and these persons were circularised a second time, and on this occasion by means of a registered letter. This proceeding had a satisfactory outcome, inasmuch as in the majority of cases a reply was received, many of the practitioners, in answering the registered inquiry, having the grace to express their thanks for the trouble which had been taken to ensure their names remaining upon the Register. Still, for England and Scotland 584 names remained unaccounted for, and in the case of Ireland 134 names. A third inquiry, again by the medium of registered letters, reduced the total number of persons present on the

1909 Register who could not be traced to 463 English, 362 Scottish, and 135 Irish—a total of 960. These names had to be erased.

We heartily commend the action of the Council in authorising this exhaustive revision of our professional roll. For a total net expenditure of £164 7*s.* 2*d.*, of which about £88 can be charged to the accounts of 1908, the whole of the Register has been exhaustively examined. Looked at in any way, this is a most meritorious accomplishment. It now remains for the members of the medical profession to coöperate with the Registrar in maintaining the roll in its present condition of accuracy. A correct Register is one of the principal assets of the existing Medical Acts; to obtain it our medical forefathers waged sturdy warfare with recalcitrant politicians, and it is the duty of all of us to assist the Registrar in his difficult task. There are those who say that they see no advantage in being upon the Register, because there is no real good to be derived out of any legal separation from the vast army of quacks as long as the Medical Acts are powerless to stop unregistered medical practice. The answer to this is quite conclusive. The Medical Acts are not final; so far are they from being final that their revision in some direction that will curtail the present licence of quackery may fairly be expected. When this question comes on the political *tapis*, the fact that the official roll of the medical profession is thoroughly well kept will certainly be an argument in favour of strengthening the position of the practitioners whose names appear upon it.

The Nature of Cancer.

WE published in our issue of May 28th an interesting article by Dr. A. T. BRAND, with which some of our readers agree and some disagree—this we know from correspondence which we have received—while in the present state of our knowledge we are not called upon to return any verdict upon the evidence adduced. Our purpose in publishing the article has been served. Such papers keep before all minds the facts that, while the great question as to the origin of cancer remains unsolved, a large number of indefatigable workers are attacking the problem from different points of view, the ground is being cleared in many directions, specious theories are being proved untenable, and special successes are being found not to be the rule in general circumstances; and as a result of all this each new worker who comes into the field is able to spare more of his time either to formulate new theories or to attack theories which are not satisfactory. Dr. BRAND is a whole-hearted believer in the infectivity of cancer, and lays great stress throughout his paper on the arguments in favour of a microbic origin of the disease. He draws analogies which have been drawn before, and some of which are certainly striking, between the course of cancer and the course of microbic diseases; and in many ways his communication to our pages may be regarded as a summary of the statements and speculations of those who favour the view of a parasitic origin of cancer. His attitude towards surgery is dictated by that view, but is hardly so kindly a one as that of other observers of his way of thinking. He has omitted to note that the most valuable treatment in such an infective disease as tuberculosis may be surgical; while we are certain that by reference to our own columns he could find many series of cases in which the results of operation for malignant disease had been happier than his words would lead us to believe. Undoubtedly, however, operations of every kind for excision of a malignant growth at its place of local origin are successful in direct proportion to the early date at which operative interference is sought. As a natural rider to his acceptance of the microbic origin of cancer, one of Dr. BRAND'S suggestions as to prophylaxis is inspired by the great frequency with which the alimentary tract is involved in malignant processes. He considers that this frequency points to food or drink being the medium of the entrance to the body of any organism, and urges consequently the need to avoid all uncooked food.

Such opinions upon the specificity of cancer have been commonly held for some years, but of late those who have followed the progress of the comparative and experimentative study of cancer are asking for proofs of the belief that cancer is as typically an infective process as syphilis or tuberculosis. What, in fact, is the scientific justification for the statement that "there must of necessity be an intracellular influence which endows it (the cancer cell) with its malign parasitic power. In other words, there must be an intracellular parasite, and all parasites are extrinsic." No one is yet in a position to contradict this, and it is, of course, the conviction of many beside the author, but it must be pointed out that the conviction rests only on analogies. In some places Dr. BRAND seems to us to be unfamiliar with the bearing of the work of biologists, or he interprets their work in a different way from the majority of pathologists. It has been demonstrated, and we believe it is generally acknowledged, that the successful transference of cancer from one individual to another has no connexion with infection, but is as truly a transplantation as is the bedding-out of, say, a geranium. A transplantable tumour growing to-day in the "soil" of thousands of mice scattered throughout the world, and growing eight years after it was first grafted from the parent host, the mouse in which it arose, is just as certainly a direct lineal descendant as the Lombardy poplar trees growing throughout Europe are the descendants by grafts or cuttings from other individual trees which died 100 years ago. No one supposes that the soil is infected with poplar trees because the soil is not converted into them, and no more are the tissues of animals supplying the "soil" for cancer grafts converted into cancerous tissue. Therefore the transplantation of cancer, if it does not absolutely disprove, as many hold, Dr. BRAND'S thesis, certainly lends no support to it. Again, Dr. BRAND entirely misinterprets the fact that connective-tissue new growths (sarcoma) have been observed to arise during the propagation of epithelial new growths (carcinoma). This fact observed by EHRLICH, APOLANT, BASHFORD, MURRAY, HAALAND, RUSSELL and others, has not been interpreted by those most competent to judge, to mean "that one and the same parasite is sufficient to originate any and every variety of malignant neoplasm";

indeed, the possibility of the transference of an intracellular parasite has been expressly excluded by some observers.

As will be gathered, we do not see eye to eye with Dr. BRAND with regard to the infectivity of cancer, though we thought it useful to publish his paper. His remarks will certainly accentuate the value of early diagnosis of cancer and of prompt resort to the surgeon. They also serve to marshal before the mind the evidence of the infectivity of cancer, and so to lead to the question whether this evidence is satisfactory. In this way they form a challenge to, rather than a defence of, the doctrines which he expounds. And it is, we think, particularly valuable that the problem of cancer should be kept constantly before our minds. It is no reproach to medicine that the solution has not yet been reached, and this is a point worth making. If a microbic origin of cancer had been proved it would be sad that medicine should be slow in working upon the indicated lines. But we have not got to this position. It is not a reproach to physics that the nature of positive or negative electricity is not as yet known, and there are no complaints of this gap in scientific knowledge, because the public cannot see that its closing up would lead to any material benefit. But the discovery of the nature of cancer might be an incalculable boon to the human race, so that the mystery which still surrounds the origin of cancer is too readily regarded as a reflection on the medical profession. We are at the present much in the dark, but the fault cannot be attributed to medicine, while it is certain that free discussion and a rigid scrutiny of every so-called fact, before it is accepted as a fact, cannot fail to cut short the term of our ignorance.

Medicine in the Senate House at Cambridge.

THE Universities of Oxford and Dublin having given to the light the "orationes" in which their public orators have recommended for honorary graduation the meritorious of the contemporary world in literature and art, in science and affairs, the sister seat of learning, Cambridge, has followed suit in a volume of similar scope but of far superior bulk, covering, as it does, a wider area of interest and including names and achievements connected with them well-nigh exhaustive in point of number and classification.[1] It would be invidious to pursue the comparison further and to attempt to show wherein Dr. SANDYS, in characterising the same graduands, has shown a more delicate artistic touch or expressed himself in happier Latinity. Such an undertaking would be as ungracious as it would be difficult, and, even if successful, would still leave a not inconsiderable minority of readers unconvinced that the palm in miniature painting did not really rest with Dr. MERRY, or that Professor PALMER and Professor TYRRELL had even yet found their rivals in felicity of allusion or in finish of scholarship. The three volumes, be it said at once, are in the highest degree honourable to the universities from which they come, and cannot but evoke the admiration (we refrain from adding the envy) of other seats of learning not less hospitable in the admission of "novi cives," if not so inspired in the style and language in which that hospitality is conveyed.

Latin, while no longer claiming to be the universal language which humanists like GEORGE BUCHANAN and reformers in science like FRANCIS BACON fondly believed it would remain, has qualities of its own which make it the best of vehicles for that concentrated portrait painting in which the characterisation of a candidate for academic honours really consists—its lucidity, its brevity, its dignity, combining with its fixity (exempt from the passing fashions which render English so variable from generation to generation) to give it a monumental precision and impressiveness unknown to modern tongues. It was some such consideration that induced so competent, so fastidious, a critic as MATTHEW ARNOLD, charmed with the august diction and the noble cadences of the Cambridge orator in recommending him for graduation, to write in acknowledgment: "I can only say that I could wish the next age (if the next age inquires at all about me) to read no other and no longer character of me than yours." The same must have been felt, if not expressed, by hundreds of distinguished men introduced for a similar honour, and among these we are glad to think that the medical profession is included in the person of many past masters in research, in practice, and in teaching who, disinclined *ἐν ἀμουσίᾳ καὶ ἀμαθίᾳ καταβιῶναι*, are truly gratified to see their personality reflected in language familiar to the learned of all other nations, language which CICERO himself could read with the double pleasure of finding his own idiom and cadence still *puissant* in handing down great men to posterity. And not only are these portraits complete in themselves, veritable cameos in delineation and expression, but they are accompanied with a marginal annotation which creates, so to speak, the atmosphere, the light, in which they are to be perused, the series as it runs from page to page being furnished with a *catalogue raisonnée* from which the student may gather the title deeds to distinction possessed by each graduand.

The amount of reading, not to say research, by which Dr. SANDYS has qualified himself to recommend each candidate for academic honour is simply marvellous, and in the medical sphere, of which we may be permitted to speak, we envy and admire the thoroughness and intelligence with which he has mastered the great "momenta" in the history of medicine, revealing a familiarity with HIPPOCRATES, with CELSUS, with GALEN, to say nothing of mediæval and modern pioneers, rare even among the dilettanti of the profession. Repeatedly, for instance, we are reminded of the keynote of all medical truth sounded by the father of the healing art and echoed by the Roman patrician who has justly been called the "Latin HIPPOCRATES": "Sine rerum Naturæ cognitione trunca et debilis est medicina"—a dictum which, like many others contained in the "De Medicina," in its masterly "praefatio" particularly, must satisfy the most exacting pleader for a "scientific side" in our secondary schools. We deny ourselves and our readers the pleasure of quoting even a few specimens of the many felicitous allusions, literary, historical, and scientific, with

[1] Orationes et Epistolae Cantabrigienses (1876-1909), by John Edwin Sandys, Litt.D., Fellow of S. John's College and Public Orator in the University of Cambridge. London: Macmillan and Co. 1910. Price 0s. net

which Dr. SANDYS seasons the gravity of his "orationes." We prefer to suggest that they should read the book and enjoy at first hand a wit and play of fancy not usually associated with severe study or academic proficiency, which make not a few of the "characterisations" quite memorable for a chastened pleasantry which can be as universally appreciable in its essence as the language in which it is couched is intelligible. Another feature of the volume which must endear it to all lovers of learning and literary form is the array of "epistolæ," congratulating this or that university on the recurrence of a fête day notable in its annals, or welcoming to Cambridge such professional bodies as the British Medical Association. In these "epistles" Dr. SANDYS is not less happy in thought, in sentiment, and in technique than in the gallery of portraits to which he treats us in introducing candidates for graduation. He thus worthily sustains the honour not only of his own Alma Mater but of the sister seats of learning throughout the English-speaking world for a sympathy, as catholic as it is fraternal, with the cause of academic progress under whatever nationality it works or whatever the civilisation it aspires to promote.

Annotations.

"Ne quid nimis."

THE INFLUENCE OF ENVIRONMENT ON INTELLIGENCE IN SCHOOL CHILDREN.

IT has been an unfortunate, but perhaps inevitable, consequence of the complex character of social phenomena that they have remained to a great extent outside the range of scientific investigation, so that the methods recognised as necessary in the pursuit of truth in relatively simple matters have been virtually set aside in dealing with problems which in a special degree call for the exercise of trained and disciplined habits of thought. Within recent years, no doubt, this condition of things has changed, at least to the extent that a science of sociology has established its right to a separate existence, but it must be admitted that what the new science has so far achieved has been mainly to bring out more clearly the enormous difficulties of its subject matter and to emphasise the uncertain and tentative character of its inferences, and their consequent inadequacy to serve as guides in action. Even the most ardent students of social science have had to recognise the force of these limitations, and to acknowledge that the day is still very far distant when their science may hope to inspire an art of politics which shall stand to the politics of to-day as modern medicine stands to the incantations of the witch doctor. Of late, however, there has seemed to be a promise of more rapid progress with the introduction into sociological research of those modern statistical methods which, if they are found to have anything like the range of application and the accuracy of result claimed for them by the leaders of the biometric school, should enormously increase our knowledge of the factors of social evolution and consequently our power to influence these factors to definite ends. Unfortunately, the "edita doctrina sapientum templa serena" from which the biometrician looks down on the groping efforts of ordinary mortals are somewhat remote and hard of access; their atmosphere, too, is trying to benighted individuals unused to breathe the rarefied air of the higher mathematics, and the messages that descend from these chilly regions are generally wrapped in language which is anything but simple. This is doubtless the reason why the incursion of the biometric expert into the field of sociology has hardly as yet aroused the interest of a very wide public, despite the fact that the results which he already claims to have obtained are of a kind that should profoundly modify the direction of social legislation. As a striking example of the significance of these researches in their bearing on practical issues we may refer to a very remarkable investigation regarding the influence of unfavourable home environment and defective physique on the intelligence of school children, which has been recently carried out by Mr. David Heron at the Galton Laboratory of Eugenics, an institution which owes its being at once to the genius and to the generosity of Sir Francis Galton. The material used by Mr. Heron was obtained from data collected in a pioneer school survey organised at the instance of Dr. J. Kerr, the London County Council School medical officer, and comprised observations referring to 12 boys' schools and 13 girls' schools in different parts of London and attended by children of different social condition. Estimates of the mental capacity of the several children were furnished by the teachers, and particulars were obtained from the school medical officers regarding the height and weight of the children, the state of nutrition, the condition as to cleanliness, and other points taken as indicative of the character of the home environment. From these data, treated by the modern statistical methods, Mr. Heron determined for each of the conditions dealt with a measure of its relationship to the degree of mental capacity. Taking as the standard of comparison the correlation between characters in parent and offspring, which biometric observers have estimated as about 0·45 to 0·50 (complete identity being represented by 1), Mr. Heron lays it down that the correlations found between the degree of mental capacity and the several conditions, which are held to indicate the quality of the environment and the state of physique, cannot be regarded as significant unless they approach that figure or are at least as much as 0·3 or 0·4. This requirement was not fulfilled in the case of any of the conditions examined. The correlations found were for the most part quite small and of irregular sign, so that sometimes, for instance, in the same school the boys showed increased intelligence and the girls less intelligence with better environmental factors or physique and *vice versâ*. From these negative results two conclusions are drawn by Mr. Heron, firstly, that there is room for improvement in the statistical data, and secondly, that there is "no sign of an environmental condition producing an effect on the mentality of the child at all comparable to the known influences of heredity." The dispassionate critic will probably be more ready to assent to the first than to the second of these conclusions, or, as it would be perhaps more correct to say, he is likely to be so much impressed by the extremely unsatisfactory nature of the data that he will be disposed to refuse all validity to the conclusions drawn from them, even when these conclusions have been reached by the aid of the most abstruse formulæ. Mr. Heron, indeed, admits to the full the objections that can be taken to the character of the material which he has utilised, and he even adds to their number by suggesting that in the school population of the metropolis there are significant differences in racial type which must imply corresponding differentiation, not only in stature and weight, but also in such points as the standard of clothing. Even if we do not assume that characters of pigmentation have all the significance from this point of view that Mr. Heron would assign to them, it is sufficiently clear that the material dealt with is in other respects so lacking in homogeneity and in accuracy as to be quite unreliable. To take, for instance,

the vitally important point in such an inquiry, what value are we to attach to a merely subjective estimate of the degree of mental capacity? So enormous is the influence of the personal equation of the teacher in the estimates used by Mr. Heron that in one school—a school attended, it may be remarked, by children of parents in the casual labour class—no less than 33 per cent. of the pupils are described as "brilliant," and a further 35 per cent. of the boys and 22 per cent. of the girls are returned as "above the average," while in other schools the ratio of "brilliant" scholars sinks as low as 1 per cent. These figures, to which Mr. Heron very frankly calls attention, certainly suggest that data for statistical inquiries of this sort can hardly be obtained in a satisfactory form unless the factors to which the data refer are clearly defined and accurately measured. Until these conditions have been fulfilled such investigations must appear premature, and their results, however interesting and suggestive, will not be likely to carry much weight even with convinced adherents of the biometric methods of research in sociological problems; to more sceptical and more frivolous spirits they may even seem an argument in support of the cynical theory that statistics are the superlative degree of unveracity.

THE DANGERS OF PETROL IN GENERAL AND OF THE DRY SHAMPOO IN PARTICULAR.

IT is not a great many years ago when the storage and transit of petroleum, whether of the light or heavy kind, had a relatively small concern to the public, and the Petroleum Act of 1871 appeared to work well. All this has been altered by the suddenness with which motor traffic came to the front. As is pointed out in the recently-issued (first) report of the Departmental Committee on Petroleum Spirit, the trade in petroleum spirit was small compared with its present dimensions, and the increase in this trade has reached a stage undreamt of by the framers of the Act. There is now scarcely a village in this country at which motor spirit is not obtainable, and therefore omissions which at the time of the passing of the Act of 1871 were of comparatively small moment, and which could be neglected without great danger, have now assumed an importance which the Committee very rightly considers renders further legislative measures desirable. The committee has accordingly drawn up recommendations applying to the safer conveyance of spirit by road, to the enforcement of regulations by local authorities, to increased precautions to be taken in the manufacture of petroleum spirit and in the domestic use of petroleum spirit, to its use by hairdressers and storage by motorists, and so forth. There can be little doubt that a large section of the public still does not realise the dangerously inflammable nature of petrol, and it would be criminal to await the lesson of a great disaster instead of putting as soon as possible into legal shape requirements which are calculated to impress the necessity of exercising care when petrol is handled, and to prevent accidents arising from negligence. As our own columns have abundantly shown, the domestic use of petrol as a grease remover and cleanser in general has led to serious accidents, while its employment by hairdressers as a cleanser and rapid drier for ladies' hair has received from us unequivocal condemnation on account of the terrible events which have happened by the firing of this highly inflammable liquid during the cleansing process. Several lives have at all events been lost from this cause, and the deaths have been of a most agonising description. We are glad, therefore, to learn that the Committee is of opinion that the use of petroleum spirit hair-washes in hairdressing establishments should be prohibited, and that it recommends that in future legislation it should be made illegal for any hairdresser to use petroleum spirit or mixtures containing it on the hair of the living subject. We are glad also to find that the committee agrees with us when we wrote in an annotation in THE LANCET of July 24th, 1909, "We doubt whether these dangerous dry hair-washes are necessary at all." The evidence before the Committee included that of the Master of the Incorporated Guild of Hairdressers, who said that he had never used petroleum spirit for dry shampoos, and considered it unnecessary, while a resolution was passed by the guild discountenancing the use of dangerous shampoo compounds on the ground that there were sufficient perfectly effective and satisfactory harmless washes available. With all this we entirely agree, and we would prohibit also the use of other volatile cleaning and drying agents such as carbon tetrachloride, the use of which has recently been shown to be attended with considerable risk owing to its strong anæsthetic properties. As we have pointed out, a wash containing soap, distilled water, weak ammonia, and a little alcohol to expedite the drying, answers admirably as a cleansing agent for the hair, and no excuse that the use of highly dangerous liquids saves time and increases profit should be entertained for a moment.

THE MEDICAL DEFENCE UNION.

THE annual report of the Council of the Medical Defence Union is of a highly interesting nature. The legal statement made by the solicitor, Mr. W. E. Hempson, shows that there has not been a single adverse verdict on any of the cases taken into court on behalf of members. The applications for help have been extensive and the work carried out by the executive has been greatly increased. The members have the satisfaction of knowing that in all matters which pertain to medical practice, and which involve professional principles, they can, if in doubt or difficulty, by placing such before the executive, obtain what amounts to expert advice at no cost to themselves beyond the annual subscription. The advantages of this society are so well known that it is perhaps redundant again to set them forth in detail; but it may be stated that, in conjunction with the indemnity insurance effected for those members who have applied for it, no legal costs need be incurred by such members when it is necessary to defend themselves in any action at law brought against them, and in which the defence is undertaken by the Union. The report presented by the Union is well worthy of study. The number of cases legally conducted during the past year amounted to 158. Of these, 46 related to the suppression of libels and slanders upon members; 40 involved the defence of members in actions for alleged negligence or want of care and skill in which pecuniary damages were claimed; 10 were directed to the suppression of unqualified practice and the prosecution of unregistered practitioners; and the remaining 62 concerned matters personal to the interests of members as distinguished from those embraced under the heads given above. It must be borne in mind that the cases above referred to are only those which are necessary to be placed in the hands of the solicitor for legal intervention. The general secretary, Dr. A. G. Bateman, adjusts a large number (amounting to hundreds) of cases yearly without the assistance of the solicitor. Some statistical tables are given, showing the number of cases yearly dealt with by the solicitor since 1896, with the legal and total costs involved, which plainly indicate the enormous amount of work which has been accomplished. No member of any branch of the medical profession is free from the attack of unscrupulous persons. We strongly impress

upon our readers the great advisability of all medical men becoming members of the Union or of one of the kindred societies. The subscription lists opened to defray the expenses of legal actions which have fallen upon practitioners who had not exercised the precaution of thus protecting themselves afford strong proof of the misfortunes which may befall a medical man who is absolutely innocent of the charges or insinuations brought against him. Such charges are in the great majority of instances brought by persons possessing no means, so that when a verdict is given against them the defending practitioner is unable to recover any costs. When a member of a defence society is so attacked, all pecuniary liability and much worry and anxiety are thereby saved. The financial position of the Medical Defence Union is a very strong one, and we can cordially congratulate the officers and Council of the Union on the success they have attained during the past year.

THE OXIDASES.

IN a critical review of the literature of the oxidases and other oxygen-catalysts concerned in biological oxidations Dr. J. H. Kastle[1] presents many facts that are of considerable importance to the physician, the sanitarian, and the biological chemist. Recognising that the oxidases and their congeners belong to the same group of bodies as the sera, viruses, toxins, and antitoxins, it is clear that any facts which throw light on the one class of substances will doubtless assist ultimately in bringing about a better understanding of the whole group of biologically active substances. Portier is of the opinion that the oxidases play an important part in defending the organism against pathogenic micro-organisms, and according to Sieber they are able to destroy toxins, notably those of diphtheria and tetanus. Furthermore, they are of importance in enabling us to determine, within certain limits of temperature, whether a given sample of milk has been pasteurised or not. After reviewing the various theories of oxidation that have been propounded by Lavoisier, Schoenbein, and others, Dr. Kastle shows that the peroxide theory of oxidation of Traube, Engler, Bach, and Manchot accounts for the phenomena of auto-oxidation and oxygen-carrying upon the supposition that spontaneously oxidisable substances have the power of combining with partially dissociated molecules of oxygen to form peroxides, which in turn may react either with additional amounts of the auto-oxidisable substance itself or with some other substance to form simpler oxides. Thus it may happen that one substance may effect the oxidation of another substance which is not directly oxidisable under ordinary conditions. In the life cycle of plants and animals many changes are met with which, in so far as oxygen is involved, find their simplest explanation in terms of this hypothesis. During the absorption of oxygen by plants various substances are produced that are capable of effecting oxidations which ordinarily cannot be brought about by molecular oxygen alone. These substances are the oxidases, or oxidising ferments, and they are characterised by great instability. Closely associated with this remarkable group of substances are the peroxidases and catalases, which have the power of decomposing hydrogen peroxide or rendering active the oxygen which it contains. The oxidases are found in many animal tissues, where they are assumed to play an equally important part in oxygen metabolism. Carnot found oxidases in the saliva and other secretions, and Portier has pointed out that certain oxidases are concentrated in the epidermal and exposed structures of the organism as a defence against invasion by micro-organisms. According to Sieber, the fibrin of the blood of a normal horse gives no oxidase reactions, whereas that obtained from the blood of a horse immunised against diphtheria gives a blue colouration with guaiacum, indicating the formation of oxidases in the blood as a result of immunisation. Tyrosinase, one of the active oxidases, is the active agent in the production of melanins, and is of profound significance in its relation to certain pathological conditions of melanogenesis in man. In this connexion, Hougonenq and Paviot claim to have found that certain malignant tumours give the guaiacum reaction. According to Bourquelot the oxidases belong to the class of enzymes, and possess the following characteristics common to enzymes in general: (1) catalytic power—viz., power to effect the transformation of an indefinite amount of material by means of an infinitesimal quantity of the ferment; (2) like other ferments, their activity is subject to regular and constant influence by heat, increasing in oxidising power, with rise of temperature to 42°–45° C. (optimum temperature), then falling off in activity with further rise to 60°–70° C., and finally being completely destroyed at 100° C.; (3) insolubility in alcohol; (4) solubility in water and in glycerine; (5) adsorption by precipitates (colloids); and (6) absence of power to dialyse. The following classification of the oxidases and other oxygen carriers concerned in biological oxidations is suggested by Dr. Kastle: (1) laccase, ferments oxidising guaiacum and other organic substances directly by means of atmospheric or dissolved oxygen and without the intervention of hydrogen peroxide; (2) tyrosinase, ferments acting on tyrosin and related substances; (3) aldehydase, ferments oxidising aromatic aldehydes and related compounds; (4) indophenol oxidase (Spitzer), ferments oxidising a mixture of α-naphthol and paraphenylene diamine to indophenol and other substances; (5) the purin oxidases; and (6) glycolytic ferments, causing the disappearance of sugar from animal tissues. In addition to the oxidases proper, Dr. Kastle recognises: (1) peroxidases, which oxidise only in the presence of a peroxide; (2) catalases, ferments which decompose hydrogen peroxide but are incapable of effecting the oxidation of oxidase reagents by means of the peroxide; and (3) oxygen carriers (not true ferments), including such substances as the iron-containing pigments of the blood. They activate the oxygen of a peroxide, but differ from the true peroxidases in having greater stability. Numerous investigations have shown that the oxygen-carrying power of laccase and other oxidases is in some way associated with the presence of manganese, iron, or copper, and the same is true of the peroxidases. Thus Kelley has recently shown that pineapple plants, containing a high percentage of manganese, contain a more active oxidase than plants which are poor in this element. It is probable that these elements essentially enter into the composition of the oxygen carriers present in the living organism. Attempts have been made, therefore, to prepare artificial oxidases by means of certain preparations of iron and manganese, and the results are of great interest. Thus, Trillat found that when a small quantity of manganese was added to a 3 per cent. solution of fresh egg albumin, and the solution made faintly alkaline with caustic soda, it possessed great oxidising powers similar to those of a solution of an oxidase. It was found that the artificial oxidase obtained in this way could be precipitated by means of alcohol, and redissolved in water without losing its oxidising powers. The analogy is increased by the fact that heat destroys the oxidising power of such solutions. It is evident, therefore, that colloidal solutions of manganese hydroxide obtained by the action of caustic soda on the salts of manganese in the presence of albumin and similar colloidal substances exhibit

[1] Bulletin No. 59, Hygienic Laboratory, United States Public Health and Marine Hospital Service, Washington, D.C. 1910. Pp. 164.

properties closely resembling those of the natural oxidases. These considerations may throw further light on the therapeutic application of compounds of manganese and iron with albumin and peptone, and may account for the reputed advantages of preparations of this type over the inorganic forms of iron and manganese. It is interesting to note that Garrigou has found that certain metals exist in a colloidal state in mineral waters, and so possess the properties of natural oxidases. In this way he accounts for the beneficial results which attend the drinking of such waters, due to the setting up of more vigorous oxidations in the tissues. In confirmation of the work of Trillat it has been shown by Lumière and Chevrotier that emulsions of iron, cerium, and manganese with albumin, gelatine, or gum, produce artificial oxidases which have the power of destroying the bacterial poisons. They found that the death of an animal by tetanus toxin was greatly delayed by the administration of these artificial oxidases, and that with a slightly acid oxidase and tetanus toxin the animal did not show the slightest sign of intoxication. Dr. Kastle's valuable review is accompanied by a very useful bibliography containing references to 467 original papers.

THE PREVENTION OF INFANTILE MORTALITY IN GERMANY.

ON p. 1569 of our current issue will be found an article on the Prevention of Infantile Mortality in Hesse which describes a practical means of lessening an evil that is engaging the attention of almost every country. Other German States we learn are about to follow the example of Hesse, while the city of Berlin intends to devote £17,550 during the present year towards combating infantile mortality. Next year the town of Dresden intends as an experiment to distribute "nursing prizes." A mother who nurses her infant for three months will at the end of this period receive 20 marks (£1); if she continues to nurse it for another two months she will again receive the same amount, which will also be granted after a further period of two months—i.e., if a mother nurses her child for a period of seven months she will receive in all £3. For this purpose £500 will be provided, as well as £50 to be distributed as prizes to midwives interested in promoting this kind of social reform.

LATENT CANCER OF THE STOMACH WITH METASTASES IN THE BONE MARROW AND BLOOD SUGGESTIVE OF PERNICIOUS ANÆMIA.

CANCER of the stomach is frequently accompanied by severe anæmia, which is usually of the secondary type, and is likely to be more marked if there are numerous metastases. If the metastases occur in the bone marrow there may be characteristic changes in the blood, of which the most important is the presence of numerous erythroblasts and myelocytes. In the *Glasgow Medical Journal* for April Dr. A. W. Harrington and Dr. J. H. Teacher have reported a case in which the changes were suggestive of pernicious anæmia. A woman, aged 64 years, was admitted into the Glasgow Royal Infirmary on August 9th, 1909, complaining of pains in the back and legs, which began in June. Occasionally she vomited brownish material and passed black motions. On admission there were marked anæmia and emaciation. The sacral and gluteal regions and the back of the left thigh were tender. Examination of the abdomen showed only slight distension. Blood examination revealed: erythrocytes 1,600,000, leucocytes 14,000, hæmoglobin 35 per cent., and colour index 1·09. A differential count of the leucocytes gave the following percentages: polynuclear neutrophiles 63, polynuclear eosinophiles 0·7, lymphocytes 16·7, large mononuclears and transitionals 18·8, and myelocytes 0·8. There were 29 megaloblasts and 4 normoblasts to 500 leucocytes. On some days the stools were offensive and tarry, and evidently contained much blood, but there was no melæna after August 15th. The patient rapidly lost ground and died on Sept. 15th. At the necropsy old fibrous adhesions and white patches of tumour were found on both pleuræ and on the diaphragm. The stomach was attached to the liver by hard, white, fibrous tissue. About 2 inches of the lesser curvature were occupied by what appeared to be a simple chronic ulcer, but the gastrophrenic and gastrohepatic ligaments and the great omentum were permeated by hard white tissue. In addition all round the ulcer was a hard flat tumour with raised margins which almost encircled the stomach and caused an hour-glass contraction about its middle. The abdominal lymphatic glands were also involved. The ribs showed no nodular thickening, but they were brittle and their cancellous tissue was uniformly occupied by pale fibrous-looking material. Both femora and the right humerus and some vertebræ were examined and showed metastases. It is noteworthy that the blood condition was quite different from that usually seen in the anæmia of cancer of the stomach and was suggestive of pernicious anæmia. But there were points of difference. Such a large number of erythroblasts is unusual in pernicious anæmia, and if they do occur it is only for a short period. In this case many examinations were made and the erythroblasts were always numerous. Again, the leucocytosis with a large proportion of polynuclear neutrophiles did not favour the diagnosis of pernicious anæmia. The pains in the bones were evidently due to the metastases. The literature of the blood changes in the bone metastases of cancer is still very scanty. The recorded cases have in common marked diminution of red corpuscles, high colour index, megalocytosis, and constant presence of myelocytes and erythroblasts in considerable numbers, many of the latter being megaloblasts. Grave anæmia may occur in cancer without metastases, but the occurrence of metastases in the bone marrow is followed by the appearance in the blood of erythroblasts and myelocytes in large numbers. They appear to be due to stimulation of the marrow by the metastases. In a case in which there is reason to suspect cancer the constant presence of these cells should suggest bone metastases. The presence of pains in the bones would support the diagnosis.

MEDICAL INSPECTION OF SCHOOLS IN THE DISTRICT OF COLUMBIA.

IN view of the importance which is now attached to the medical inspection of school children, an American correspondent sends us the following note on medical inspection of the schools of the district of Columbia, which contains the capital city of the States:—"For 55,000 children in 135 buildings there are 12 inspectors, of whom eight are white. Each receives $500 per annum. The inspector visits the school at 9 A.M., after the teacher has inspected the classes for acute illness. Sick children are sent to the principal's room or to a special room to meet the inspector, who, after making a diagnosis, informs the parent if the child requires an excuse from school. Only the newer buildings have special examining rooms, and there is no routine inspection of all children, which would require a larger number of inspectors, as over 1000 scholars enter each year. It is the general opinion that even these few inspectors are a distinct protection to the community. Epidemics are much mitigated and measles no longer goes though a school like a prairie fire. But time in such circumstances is lacking to examine for defective sight or hearing, for adenoids, unsound teeth, or nervous

conditions. Twelve schools are provided for defective children and six for the incorrigible, and here all the pupils are medically examined. So far as it goes, the method of inspection has given satisfaction, parents rarely objecting, and some being solicitous of more being done than the Health Office can as yet perform. The greatest trouble has been with parents who want to have the school closed because a few zymotic cases have occurred. As the 'contacts' are all segregrated and inspected, there is no need for this; while the infected room is usually at once closed and fumigated, and any parent is at liberty to keep his child away for some days if infection is feared." With regard to nurses, it appears from our correspondent's note that the Chief Inspector of Education strongly believes in the efficacy of visiting school nurses. Three of them have now been appointed in consequence of the excellent work done by a nurse who was lent to the Health Office last year by the Board of Charities.

ADVANCED UNRUPTURED TUBAL PREGNANCY.

IN the great majority of cases of tubal pregnancy rupture or abortion occurs in the early stages of development. In a few cases the pregnancy continues as an intra-ligamentary gestation, the layers of the broad ligament becoming opened up by the developing fœtus and full term being reached ultimately with, as a rule, the occurrence of a false labour and the death of the fœtus at that time. In a very small percentage of the cases, exactly what percentage is difficult to say, the fœtus continues to develop in the tube, and remains within it after its death or until it is removed by operation. The exact anatomical relations of the sac in a case of extra-uterine gestation when an operation is undertaken at full term are always exceedingly difficult to determine, and indeed there is often a difference of opinion as to the exact nature of the sac after it has been removed and has been examined at leisure in the laboratory. There is therefore a natural scepticism on the part of obstetricians to accept as certain cases of so-called tubal pregnancy in which the fœtus is said to be contained wholly within the tube even at full term. In a case of this kind recorded by Mr. Jonas Morris in THE LANCET of May 28th, the sac is described as formed by the unruptured right Fallopian tube. It is impossible, however, to accept as certain such a case unless a most careful microscopic examination of the whole wall of the sac has been carried out. This naturally is a difficult thing to do, owing to the fact that in many instances the parts are considerably damaged during the operation. A considerable number of cases have now been put on record in which the unruptured Fallopian tube has been considered to contain a fœtus at or near full term, and although it appears hardly a physical possibility when we consider the small calibre of the tube, yet a case such as that published by Amos[1] seems to afford definite proof of its occurrence. The patient, a woman, 35 years of age, was admitted under the care of Professor Olshausen two months after the date at which she had expected her confinement. Extra-uterine pregnancy was diagnosed, and on an abdominal section being performed a large smooth-walled tumour was removed which proved to be a thin-walled sac containing a full-term fœtus. The placenta, which was membranous and spread out over a large area of the wall of the sac, had perforated the wall at one place and was adherent to the extratubal tissues. Microscopical examination showed that the sac was composed of the wall of the tube, muscle fibres being demonstrated all round the ovum. It will be, however, only very exceptionally that such a condition can be demonstrated with certainty, as in most of the cases the wall of the sac is so thin, especially over the situation of the placenta, that its exact nature cannot be determined, and it is impossible to say what was its precise origin. F. Jayle and L. Delherm[2] collected from the literature 16 cases of so-called tubal pregnancy in the later months, but many of their cases were recorded several years ago and but very few of them are described with such detail as to render them proved examples of this variety of ectopic gestation. Mr. Morris's case is one of such great interest that it is to be hoped he will, if possible, have a complete microscopical examination of the wall of the sac carried out, so that some proof may be forthcoming of his opinion that it is composed of the dilated Fallopian tube.

EDIBLE AND POISONOUS FUNGI.

ACCORDING to some observers, the mushroom may be regarded in dietetics as a vegetable steak; others, whilst not denying that it possesses certain nutritive value, have endeavoured to show that hitherto this value has been exaggerated. The truth is that while the chemical analysis of the mushroom would assign to it a notable proportion of protein and carbohydrate materials, experiments upon the digestibility of these substances have shown that in their entirety they are not easily assimilated. The chief attraction of the mushroom is, of course, its peculiarly pleasing flavour, a flavour which has occasionally led consumers into trouble owing to the poisonous qualities of certain of the fungi. This fact, indeed, deters a good many people from eating mushrooms, the risk of poisoning being, in their view, a real one. As is pointed out, however, in an excellent instruction recently issued by the Board of Agriculture and Fisheries, the poisonous kinds of fungi are comparatively few in number, while there are, on the other hand, some 50 species of native fungi which may quite safely be eaten. What is wanted, therefore, is a knowledge of the special features possessed by each species, and this is supplied by this little book, which can be obtained at the office of the Board of Agriculture and Fisheries, Whitehall-place, London, S.W., at the modest price of 1*s*. It contains 25 plates admirably drawn and coloured; the pictorial representations are, in fact, true to life, and so the book serves as a very useful guide to all those to whom mushrooms are a dietetic delicacy, but who hesitate to eat them because they cannot be certain of differentiating accurately between poisonous and edible kinds. It is interesting to learn that the rule-of-thumb signs for discriminating between edible and poisonous fungi are absolutely valueless, and no reliance can be placed on such assumed infallible tests as the presence of a skin that is readily peeled off, indicating an edible mushroom, or the fact that a silver spoon placed in contact with poisonous kinds becomes tarnished, or that all fungi growing on wood are poisonous. We have quoted enough to show how useful and interesting is this latest addition to the series of practical guides on agricultural and botanical questions which the Board of Agriculture and Fisheries issues from time to time.

CURE OF A LARGE ANGIOMA BY RADIUM.

AT a meeting of the Société Médicale des Hôpitaux of Paris on May 13th M. H. Dominici, M. H. Chéron, and M. Barbarin reported a remarkable case of cure of a large angioma by radium. A male infant, aged 4 months, came under observation on July 4th, 1909, with a tumour in the left supraclavicular region resembling a hypertrophied lymphatic gland in its position, shape, and size. The tumour grew

[2] Revue de Gynécologie et de Chirurgie Abdominale, vol. iv., 1900, p. 29.

so rapidly that in October it occupied the whole of the side of the neck from the clavicle to the ear. Its base measured from 7 to 8 centimetres from before backwards and from 4 to 5 centimetres from above downwards; its height was 8 centimetres. Under the tense skin resistant masses could be felt. These were found to be due to cystic bodies containing a mixture of blood and lymph. They were separated by partitions which microscopical examination showed had an angio-lymphangiomatous structure. The liquid in the cystic cavities contained normal red corpuscles and leucocytes in such proportions as to resemble the blood of patients suffering from lymphatic leukæmia. There were several hundred thousand leucocytes in the cubic millimetre, and they consisted of from 80 to 85 per cent. of mononuclears, with 20 to 15 per cent. of polynuclears. The mononuclears were principally lymphocytes. The interlocular septa consisted of a plexus of enormous blood and lymphatic capillaries buried in sclerosed connective tissue, which was infiltrated with lymphoid nodules. Though the tumour was of benign nature, it was, nevertheless, formidable in consequence of its rapid growth and its tendency soon to become the source of abundant hæmorrhage. As to operation there were serious difficulties in consequence of its position, extent, and deep infiltration of the supraclavicular region. It was therefore decided to try radiotherapy. An incision was made into the principal cavity, the contents of which were evacuated. A tube of silver 4 centimetres long, 4 centimetres in diameter, and half a millimetre thick, containing 5 centigrammes of pure sulphate of radium with an activity of 21,000, was introduced and retained for 24 hours. Three or four days after removal of the tube an intense congestive reaction was produced, characterised by enlargement and induration of the tumour and was accompanied by prostration for two or three days. The congestion diminished towards the thirteenth day and was followed by progressive reduction of the tumour and after seven weeks by cure.

PROFESSOR EMIL ZUCKERKANDL.

Professor Emil Zuckerkandl, who has occupied one of the chairs of Anatomy in the University of Vienna for so many years, died on May 28th at the age of 61 years. He was known to anatomists and medical men all the world over as a most indefatigable worker who combined in a remarkable degree the qualities of both a practical and a theoretical anatomist, while he published his observations at great length and very frequently, over 100 papers being credited to him. Some of them are large works and of real importance; all of them are records of personal observation made in a centre where anatomical and pathological material is particularly abundant. Although at first sight there seems a strange absence of sequence in the many and varied subjects which he investigated, a closer examination of his life's work will show that the many lines he followed out arose really from the first and apparently slight investigation which he made in his twenty-sixth year when acting as prosector in the Anatomical School at Vienna. The Austrian Expedition ship, the *Novara*, had then returned, and the human crania brought home were given to young Zuckerkandl to examine and describe. The museum attached to the University had a very good collection of human crania—some 355 in number—which had been brought together by Hyrtl, Carl Langer, and other occupants of the chairs of Anatomy in Vienna. Darwin's theory of man's origin had quickened the interest in human skulls in Vienna as elsewhere, and during the examination of the *Novara* collection Zuckerkandl found many difficulties in giving a satisfactory explanation of the factors which determine the shape of the facial part of the skull. To elucidate this matter he investigated the skulls in the Viennese collection, and published a monograph on the "Morphology of the Facial Skeleton" in 1877. The nose and its accessory cavities, he perceived, were the determining factors. In 1878 he was busily investigating the anatomy and diseases of the nasal cavities; in 1882 appeared the first volume of his classical work on this subject, with its 22 plates and 98 excellently and accurately executed figures, showing the various features of the nose in health and disease. He was a pioneer in this branch of medicine; his work contains the results of dissections made on over 300 bodies. Before giving up his prosectorship in Vienna to take over the chair of Anatomy in Gratz in 1887, he published his observations on the adenoid tissue in the nasal mucous membrane; while at Gratz he issued his work on the "Comparative Anatomy of the Nasal Cavities." The second volume of his work on the "Anatomy and Diseases of the Nose" appeared when he returned to Vienna to fill the chair of Anatomy in his University; and this volume, like the first, was richly illustrated and must always remain one of the first books of reference on the subject with which it deals. Minor additional papers appeared in 1893 and 1894 on the blood-supply of the nasal mucous membrane and on the conformation of the aperture to the nose. His researches on the nose led him to investigate adjoining regions of the body, chiefly with the aim of explaining the incidence and course of disease. In 1878 appeared his paper on the mastoid region; a paper on the external ear followed (1883), another on the comparative anatomy of this part (1896); and further papers appeared in 1897, 1904, and 1906. The region of the mouth, larynx, and air passages were also closely investigated by him. In 1878 he found glandular masses with the structure of the thyroid imbedded in the tongue above the hyoid. He returned to these in 1903 by investigating again the origin and development of the thyroid and thymus in the rat. In 1890 appeared his work on the "Anatomy and Disease of the Mouth," wherein he described an embryological rudiment for a fourth molar. In 1896 he published a monograph on the pulmonary air-passages; another on compression of the thorax (1897); and he examined anatomically the larynges of singers (1900). His inquiries into the nose naturally led to an investigation of the brain with a view of locating the centre for smell, and a research followed upon that part of the brain—then very obscurely understood—usually known as the hippocampal region. In 1900 appeared his monograph on the olfactory centre; other minor contributions—such as that on the fornix of the marsupial brain—had appeared previously to this, his greater paper. Other papers on the comparative anatomy of the ape's brain followed in quick succession (Ape's Brain, 1903; Marsupial Brain, 1903, 1904; On the Collateral Fissure, 1904; Occipital Lobe, 1904; Simian Fissure, 1905; Occipital Fissures, 1906; and several others). Perhaps his work on the brain is the least satisfactory part of his life's work. All these papers are prolix, long, and detailed, and wanting in grip, insight, and genius, and are likely to play no part in future progress. Zuckerkandl, as is already apparent, was a many-sided anatomist, but the list of the subjects he enriched by his researches is not finished. In 1894 he commenced a series of researches on the arterial system; a monograph on the Anatomy and Development of the Arteries of the Forearm appeared in 1894; another in the Arteries of the Leg and Foot in 1897; a third on the Morphology of the Arteries of the Extremities in 1907; also several other smaller papers. A series of papers on the viscera and anatomy of the pelvis appeared between 1889 and 1901. In 1906 he made interesting discoveries of accessory adrenal bodies. Besides his research

work he conducted the onerous business connected with his chair and kept up the great traditions attached to it. In 1890 he wrote an introductory manual for the dissecting-room, and in 1902 his "Text-book on Topographical Anatomy" appeared. He was a patient and diligent worker, too ready to publish perhaps, and somewhat urgent and short-sighted in his claims for priority. But he had the great merit, more especially in his earlier years, of keeping steadfastly in mind that the medical man studies the human body with the object of understanding and curing disease.

THE CHILD-STUDY SOCIETY.

THE annual conference of the Child-Study Society will be held at Tunbridge Wells on June 10th and 11th next, having been postponed from May 19th owing to the death of his late Majesty. The President of the society, Sir James Crichton-Browne, will deliver the opening address; Sir John A. Cockburn will speak on "The Hand as the Gate of Knowledge and Social Relationship"; Mr. John Russell, the headmaster of the King Alfred School, Hampstead, will deliver an address on "The Social Life of a Child at a Co-Educational School"; and Mrs. Higgs will speak on "The Child as Citizen." It will be seen that an attractive programme is offered. Readers of THE LANCET have already had their attention called to Mrs. Higgs's book, "Glimpses into the Abyss." In this work the author related her experiences as a denizen of many casual wards and humble lodging-houses, and offered some practical advice as to the best mode of dealing with vagrancy. Mrs. Higgs advocated a move which has now been to some extent carried out—namely, the establishment of public labour bureaux—and in many ways displayed her right to be heard as a social reformer.

THE ACTION OF RARE EARTHS ON THE HEART OF THE FROG.

THE effects of the salts of certain rare minerals on the heart of the frog form the subject of an article in a late number of the *Journal of Physiology* (Vol. XL., No. 4) by Mr. George Ralph Mines, a Fellow of Sidney-Sussex College, Cambridge, whose researches were carried on in the Cambridge physiological laboratory. The author justly observes that the study of the reactions of living tissues towards inorganic salts, which in the course of their phylogenetic history they in all probability have never met, is of value for several reasons. Such knowledge extends our information of a group of substances by the addition of physiological to their physical or chemical properties, and in such classification lies a method of attacking the problem of how the normal saline constituents of the tissue fluids exert their action and of discovering the meaning of their antagonisms and harmonies. In addition it may happen that some therapeutic agent of value is discovered. The particular minerals experimented with by Mr. Mines were beryllium, lanthanum, yttrium, and cerium, Beryllium (glucinum) is divalent; its atomic weight is 9·1, and it chemically resembles magnesium, with the salts of which metal Mr. Mines was desirous of comparing those of beryllium. In addition to investigations on the frog's heart some experiments were carried out on rabbits under an anæsthetic, which showed that the primary effects of beryllium salts were to quicken the respiratory movements and to cause a fall in blood pressure exceeding that of the corresponding magnesium salts, a lethal dose stopping the heart in diastole. These effects closely resemble the action of weak solutions of acid as described by Gaskell in 1879, but in much lower concentration. Their action is due to their hydrolysis and consequent acidity. The salts of lanthanum (at. wt. 139), cerium (at. wt. 140), and yttrium (at. wt. 39), which are all trivalent metals, resemble the action of those of beryllium on the frog's heart, but in all cases subsequent washing out with neutral Ringer's solution brings about a gradual restoration of the heart, providing the dose of the salt is roughly liminal.

THE LATE MR. MICHAEL CARTEIGHE.

BY the death of Mr. Michael Carteighe, which occurred on May 30th, the Pharmaceutical Society has lost one of its most prominent personalities. Mr. Carteighe was a member of the council of the Pharmaceutical Society from 1866 to 1870, and again from 1881 until the time of his death, and was, in fact, present at the last meeting of the council on May 4th. He was in turn member of the board of examiners, auditor, and president of the Pharmaceutical Society, holding the presidential office from 1882 to 1896. He was one of the founders of the Institute of Chemistry, of which body he was a vice-president for 11 years; he was also a vice-president of the Society of Arts from 1890 to 1896. Mr. Carteighe was a member of the council of the Pharmaceutical Society during the successful campaign undertaken to secure the legislation which matured in the Pharmacy Act, 1868, by which the sale of certain scheduled poisons was restricted to registered chemists and druggists, and under which it was laid down that certain regulations should be observed in the selling of poisons. Throughout his 14 years' presidency of the society it was his constant endeavour to raise the standard of pharmaceutical education to a higher plane and to establish pharmacy on a professional basis. He laid it down that one of the principal claims which the pharmacist had on the consideration and respect of the public was based upon his knowledge, judgment, and skill in preventing, to the utmost of his power, the abuse or misuse of poisonous substances. He held that in the sale of poisons, in any circumstances, it was the duty of the chemist and druggist to exercise the utmost pains to prevent the loss of human life, and that to that end he should not be limited in his precautions by the conditions imposed upon him by law. Mr. Carteighe was of Irish parentage and was born in 1841; his pharmaceutical education was obtained at the School of Pharmacy, while he studied chemistry at University College, London, where he became a demonstrator under Professor Williamson. He died at Goring-on-Thames in his sixty-ninth year, after a career the value of which, not only to those of his own profession but to the general public, can be hardly brought out by any brief summary of what he did.

THE Harben lectures for 1910 will be delivered by Lieutenant-Colonel Sir W. B. Leishman, M.B. Glasg. F.R.S., on June 8th, 15th, and 22nd in the lecture theatre of the Royal Institute of Public Health at 6 P.M. The subject will be Anti-typhoid Inoculation.

WE much regret to announce the death of Mr. William Rose, emeritus professor of surgery in King's College, London, the well-known consulting surgeon, and joint author with Mr. Albert Carless of the popular "Manual of Surgery."

THE death is also announced of Sir Francis Seymour Haden, distinguished as surgeon and sanitarian, but even more distinguished as an artist and as the founder of the Society of Painter-Etchers and Engravers.

Dr. Elizabeth Blackwell, the pioneer of the movement for admission of women to the medical profession, has also died at the advanced age of 89.

THE Paris Academy of Medicine has elected Dr. Gaucher to fill the vacancy amongst the members. The next highest on the list of candidates was Dr. Babinski.

MOTORING NOTES.

BY C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

The Covey Pneumatic Suspension.

THOUGH pneumatic tyres are now so improved and excellent I suppose that the motorist who has not on some occasion had a tyre delay is non-existent, and equally so the motorist who on such occasion has not wished that puncturable tyres were not needed. Thus any invention that can claim to provide this freedom from the chief worry in regard to the modern mechanically propelled vehicle has far-reaching possibilities. Until now, though many expedients have been devised as substitutes for air-inflated rubber tyres, most of these inventions have had some undesirable features, so it was with many misgivings in my mind, and in a sceptical spirit, that I recently alighted at Kew from an ordinary air-tyred car to inspect and test the invention named at the head of this article.

The arrangement consists of four dome-headed cylinders attached to the frame of the car. In each of these a piston with ordinary piston rings works; the pivotally mounted connecting rods are fixed to the axles, and thus support the car. The axles are kept in proper position by means of radius and tie rods. In the cylinders above the pistons there is air under pressure, and this forms the pneumatic suspension. The whole difference between this type and the ordinary tyre variety is that pneumatic tyres and carriage springs are done away with, and the air cushion, instead of being between the wheels and the road, is between the body and the axles. An air reservoir is attached to the frame, and contains air at a pressure of some 200 pounds, which pressure is maintained by a pump driven off the engine shaft. By means of pipes the reservoir is connected to each of the cylinders, and in these concentric inlet and outlet valves are provided. These valves are operated from the piston by springs, which are in a state of rest as long as the piston is occupying its normal position in the cylinder—that is, they are neither in tension nor compression. As extra weight has to be supported the piston rises, compresses the spring, and consequently moves the inlet valve. As the air in the storage chamber is at greater pressure a supply is immediately forced into the cylinder, until on account of greater pressure the piston resumes its correct position, when, as the compression from the spring is removed, the valve closes, stopping further air-supply. In like manner, when the weight of the car decreases, the outlet valves are opened and air is let out until the usual piston position is obtained. In this way the compressed air in the cylinder that supports the whole weight of the body and its occupants remains unaltered, no matter the load, nor the upward nor downward movements of the piston due to road inequalities. Leakage is obviated by a layer of oil over the piston head and valve seatings, which acts as a seal, and the oil is constantly circulated throughout the apparatus by the movements of the compressed air therein. It will thus be seen that the frame of the car is supported upon its axles by four cylinders of compressed air, the pressure of which does not materially alter on account of the inequalities in the road surface, and consequently the frame, engine, and other parts of the chassis float evenly and smoothly over the road surface.

I, in company with some other sceptics, was driven over some really bumpy, bad roads (and I came to the conclusion that Kew abounds in such), firstly in an ordinary tyred car, and then over the same course in a Crossley car fitted with the Cowey suspension. The difference was really uncanny; the movements were distinctly soft and silky; there was no jar, though we passed over many holes and patches of stones calculated to cut pneumatic tyres to the quick. The sensation was like a boat gliding over the water; it was a revelation, and anyone who may be tempted by this account to visit Kew and test this invention will, I am sure, not be disappointed. No matter the load, the suspension automatically adjusts itself to it. (This is, of course, not quite the case with steel springs, which are set for a certain weight, and those who have driven in a car with only two passengers when it is constructed for, say, four will recall the bumping.) When extra passengers entered the car it was marvellous how the initial lowering was recovered, and even if one shifted one's seat from one side to the other this adjustment took place, and over the worst roads no motion was felt. I certainly came to the conclusion that the claims made for this invention were fully substantiated by the three-mile drive I had in the car so fitted.

Modern cars are, of course, much better built than they were; still, road shocks are not good treatment for machinery, and especially back axles. This invention will minimise these, and the saving of wear and tear of engine, gears, &c., is alone an argument in its favour, apart from the freedom from vibration which it confers. For ambulances, too, it will be a great advantage. The invention will cost about £25 extra on a 14–20 h.p. car, after making allowance for the parts it displaces. It can be fitted to most cars, if the chassis is sent to Messrs. Cowey of Kew, Surrey, before the body is fitted, and I understand, too, that they will shortly be placing on the market a car especially made for and built with it.

An Up-to-Date Method of Sampling a Horn.

The "Gabriel" motor horn, of which mention was made in THE LANCET of April 2nd, can now be tested by ringing up telephone Gerrard 3397. Messrs. Brown Bros., Limited, have made arrangements by which the various sizes of the Gabriel horn and bugle can be demonstrated over the telephone. Thus without a journey a would-be purchaser can hear that it has a truly musical tone, and is likely to be an effective road-clearer.

The Stepney Road-Grip Tyres.

Steel-studded tyres do obviate side-slip, but they are much dearer than the ordinary tyre, and what now is certainly serious, they do not last as long. Consequently I think all motorists will welcome the road-grip tyre which the makers of the well-known and useful Stepney wheel have recently put on the market. These tyres are manufactured from the best quality rubber and canvas, and their gripping power is obtained by transverse ridges. I can bear out their claim for gripping, as I have tested them on greasy London roads in all sorts of weather and found them to be perfect non-skids. In addition they are lighter in weight and more resilient than the steel-studded tyre, and what is very important, they last nearly twice as long; in fact, I recently heard of a "taxi" driver who had driven 8000 miles with these on the back wheels of his vehicle. The specimens which I have appear to be wearing well, and there is an absence of any cuts, though I have used them over all kinds of roads, including some with unrolled freshly put down stones.

CARE OF THE INSANE IN EGYPT.[1]

FOR some years it has been evident that the 300 beds provided for Egyptian lunatics in the asylum before the British occupation were quite insufficient for the insane who ought to be under treatment. The accommodation has now been raised from 877 beds to 947 beds, while the number of patients in residence has risen from 1017 to 1150. Next year it is hoped that the new asylum at Khanka may be sufficiently advanced to relieve the pressure on the old asylum. It is calculated that in 1916 proper accommodation will be provided for more than 2000 patients in the two asylums. During Dr. J. Warnock's reign the cost per bed of construction, including equipment of the new sections opened, has been only £114, and this commendable figure would have been even lower if it had not been for the erection of a necessary villa in the grounds for the reception of paying women patients. The increase in admissions to the asylum of recent years need not necessarily suggest that the insane are more numerous than formerly, but it is only now that some steps are being taken, probably for the first time in Egyptian history, to discover the insane rate of the population. In the Census of 1907 the number of persons declared to be insane is given as 5447, but Dr. Warnock believes that "the real number of the insane in Egypt probably amounts to several times that figure." It was probably only the well-marked cases of insanity who were declared by their relatives, but as the news spreads throughout the country that lunatics in the asylum are well cared for it

[1] Fifteenth Annual Report of the Egyptian Government Hospital for the Insane for 1909. Cairo, 1910, pp. 43.

is quite likely that many of the quieter cases now concealed in their homes will eventually be certified. The total number of cases suspected to be insane and reported during the year was 1122; but of these 578 were sent to the asylum, while the remaining 544, though all admitted to provincial hospitals because they were suspected to be insane, were released without being certified. Of those admitted to the asylum as many as 328 were certified to be dangerous, and 155 were reported to be suicidal.

One of the satisfactory points about the English management of the asylum is the increasing number of patients who apply to be admitted as voluntary boarders, many of them for the second time. Some 85 per cent. of the total number of patients are treated gratuitously, but the paying wards bring in a revenue of £4000. A list of six homicidal cases is given to emphasise the folly of allowing an insane person to remain at large until he has actually murdered someone. One man, admitted in November last, had been known to be insane for many years, and was once sent to a local hospital to be certified, but he was released after a week's detention. He was then "hobbled" by his friends for a year, because it was alleged that he had already killed a girl. "In spite of his shackles he succeeded in getting a hoe and killing a labourer." This deplorable condition is caused by the ignorance of lunacy among some Egyptian medical men and their ingrained fear of responsibility.

In former notices of Dr. Warnock's reports we have alluded to his experience that acute cases are rendered more excited by hot, dry weather. He now tells us that in May, which happened to be an exceptionally hot month, 40 new patients were admitted within ten days, almost all furiously excited and restrained in camisoles. The table of the forms of insanity of patients admitted during the year is headed by mania, 128; pellagrous insanity, 101; melancholia, 44; and insanity from hashish, 43 cases. General paralysis provided 37 patients, of whom 27 had signs or histories of syphilis, 25 were reported to use alcohol, and at least 29 were town-dwellers. Patients were fed artificially by the stomach tube on 3359 occasions, and several were thus kept alive for months, having persistently refused to take food.

The evidence of the past year does not confirm Dr. Babes's belief that atoxyl has a beneficial effect on pellagrous lunatics. But this interesting report again draws attention to the fact that pellagrous patients, resident in the asylum for years, and necessarily abstaining from maize, because maize is carefully excluded from the diet of all the patients, again develop pellagrous rashes while in the asylum, with acute physical symptoms, sometimes resulting in death. For instance, a man admitted in November, 1903, developed in June, 1907, a black charred-looking rash on the neck, with diarrhœa and symptoms of acute fatal pellagra, from which he died. Such cases as this almost drive us to the conclusion that maize alone cannot be the chief factor in the etiology of pellagra; they certainly prepare us for any new pathology which the Pellagra Investigation Committee may be able to substantiate.

In the autumn 7 cases of typhoid fever were discovered in the asylum and were removed to the neighbouring infectious hospital; they included 2 female attendants, 1 male attendant, and 4 male patients, of whom 1 male attendant and 1 patient died. As there was no apparent connexion between the cases, the blood of 28 employees and patients working in the kitchens, bakery, and stores was examined, and it was then found that the chief cook, whose blood gave a positive reaction to Widal's test, had suffered from "fever" in July and had been absent from duty for a fortnight. It is considered probable that he was the typhoid carrier, and no further cases arose after the isolation of the cook and five other men whose blood also gave positive reactions. The story of the year is not all rose-coloured. 30 attendants had to be punished for ill-treating patients, 8 others for thefts, and in some of the old buildings considerable annoyance was caused by bugs in the wooden roof, rats, snakes, scorpions, and by a pest of flies.

UNITED SERVICES MEDICAL SOCIETY.—The annual meeting of this society will be held at the Royal Army Medical College, Grosvenor-road, London, S.W., at 3 P.M. on Friday, June 17th.

THE ANNUAL REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR 1908.

THE annual report of the Sanitary Commissioner with the Government of India for 1908 has just been issued, and the plan of the report is the same as that of previous years, being divided into nine sections dealing with the meteorology of the year, the health of the European and native Indian troops, the health of the prisoners in the Government jails, vital statistics of the general population, the history of the chief diseases affecting the general population, the general history of vaccination, the sanitary works in the different presidencies and provinces, and, lastly, a section dealing with general remarks. Seven sections of statistical matter are included as appendices in the form of tables, which are comparative and exceedingly useful for reference purposes.

Meteorology.

The condition of the people of India is largely dominated by the rainfall, and any considerable departure from the normal either in the amount or distribution generally sets in motion a train of consequences ending in poverty, sickness, and death. In 1908 meteorological conditions were unfavourable, the south-west monsoon of 1907 receded prematurely, and in consequence the spring crops of 1908 were bad everywhere, excepting in Eastern Bengal, Assam, and in Lower Burma, and although the autumn crops were generally good, except in Bengal, the epidemic of malarial fever which ravaged Upper India delayed the harvest. The rainfall of 1908 was abnormal: in the cold weather it was in excess but irregularly distributed; in the hot weather it was in defect, except in Upper India, Berar, and Mysore; and during the monsoon period, although in defect in the eastern parts of Upper India, it was in enormous excess over the north-west of India. In every province in India except in Eastern Bengal and Assam, and also in the Bombay Presidency, the general mortality amongst the native population was greater than usual, the increase in the death-rates being especially noticeable in Upper India, where the mortality of the previous quinquennium, with which comparison is made, was greatly increased by plague, which was happily not a serious factor in the death-rates for 1908.

The Health of the British Army in India: General Remarks.

Excluding officers the average daily strength of the European troops serving in India during 1908 was 68,933. The rates of admission to hospital were 839·5 per 1000, the mortality rate was 9·78 per 1000, and the invaliding rate was 15·64. Of these, the admission and mortality rates were higher than the previous year, while the invaliding rate was lower, partly due to the healthiness of 1907, but chiefly to the action taken by the military authorities to ensure that only those men should be invalided who were not likely to recover their health by a change to one of the hill stations in India. The increased sickness and mortality fell entirely upon the troops of the northern army and was chiefly due to the greater prevalence of malaria, but excepting venereal diseases most of the important diseases were more prevalent than in 1907. The chief causes of death were enteric fever, cholera, and abscess of the liver; more than half the increase over the rate in 1907 being due to cholera, which caused 76 deaths, as compared with 2 in that year. The chief causes of invaliding were, in order, tubercle of the lungs, debility, and valvular disease and disordered action of the heart; these together caused 361 invalidings (one-third of the total number), as compared with 811 in 1907. The admission rate for European troops during 1908 was nearly one and a quarter times as high as that for native troops, and the constantly sick rate was a little more than twice as high. During the year under review two frontier expeditions were engaged in: the Bazar Valley Field Force, the operations of which lasted from Feb. 13th to March 2nd, 1908, gave rise to 45 admissions to hospital with 1 death; and the Mohmand Field Force, which was employed from April 17th to June 2nd; the last-named expedition had 524 admissions to hospital, and 50 deaths occurred, 41 of the deaths being due to a severe outbreak of cholera. During 1908 cholera was unusually prevalent amongst the general population of India, and 93 cases with 76 deaths occurred amongst the European troops.

Of these cases no fewer than 50 were amongst the troops of the Mohmand Field Force, which was operating in a highly infected area, the Royal Munster Fusiliers being the regiment most severely implicated, having 43 cases with 36 deaths in four days. A court of inquiry appointed to investigate the cause of the outbreak in this regiment considered that it was due to the men drinking infected water from wayside sources on the march to Shabkadar. The cases that occurred amongst troops not of this field force were distributed over 17 stations, of which Cawnpore, Peshawar, and Rawalpindi were the only ones with more than 4 cases. Small-pox was also more prevalent in India and there was an increase in the number of cases amongst European troops, 53 admissions to hospital and 2 deaths being recorded, as compared with 30 admissions and 1 death in 1907. One or more cases were recorded in 20 stations during 1908; there were 14 at Lucknow, 5 at Rawalpindi, and 5 at Fyzabad. Of the 2 men that died one had been vaccinated in infancy but had not been revaccinated; the other bore no vaccination marks and there was no record of his having been vaccinated.

Malaria.

Malarial fevers caused a very large number of admissions to hospital, especially in a number of the stations occupied by the troops of the Northern Army, and this is attributed to the unusually heavy monsoon rainfall. In 1907 the admissions to hospital from malaria were 10,662 (154 per 1000); in 1908 they rose to 16,824 (224 per 1000), and the number of deaths rose from 14 to 35. Omitting stations with an average strength below 200 troops, the highest admission rates were recorded at Delhi, Meerut, Agra, Ferozopore, Multan, Peshawar, and Hyderabad, the admission rates in all these being above 612 per 1000. The Sanitary Commissioner embodies a statistical table showing the admission rates from malaria amongst European troops in India for a number of years, and one cannot fail to notice the remarkable lowness of the admission rates in recent as compared with early years. The admission rate for the decennial period ending with 1888, for example, was 485 per 1000, for the decennium ending with 1898 it was 374, and for that ending with 1908 it was only 223. To review in a detailed manner the many causes to which this reduction might be ascribed would occupy an unreasonable amount of space, but a few remarks may be made. As a result of Major Ross's discovery operations against the mosquito were started in nearly every cantonment; interest in malaria was reawakened, and especially in its diagnosis. Medical officers who believed that the inevitable outcome of starting a "mosquito brigade" would result in an immediate reduction of malaria began to be more careful in diagnosis. Whereas in former years almost every case of "fever" was entered up in the official returns as "malaria," the use of the microscope became more frequent—in fact, military medical officers were ordered not to diagnose doubtful cases as malarial fever unless the clinical signs and symptoms were confirmed by a blood examination. The change in diagnostic procedure produced a decline in recorded malaria, but at the same time it caused the admission rate from simple continued fever to rise steadily from 14 per 1000 in 1902 to 74 per 1000 in 1908. The change in diagnostic procedure was not, however, the only influence tending to lower the admission rates of malaria amongst European troops in India, for in September, 1903, there was introduced the system known as "treatment in barracks," under which patients whose disease is mild are not admitted to hospital but receive treatment as out-patients, their names not being entered in the returns showing admissions to hospital. There are, however, certain other measures which, in the opinion of nearly all military medical officers, have produced a real diminution. Of these the most important are: (1) the "after treatment" now given in all stations to patients who have been admitted to hospital with malaria; (2) the measures taken to prevent men being bitten by mosquitoes and those taken with the object of destroying mosquitoes; (3) the prophylactic administration of quinine; and (4) the retention of regiments in hill stations until the worst period of the malaria season in the plains is passed. The use of mosquito curtains is still confined to a few regiments in about nine stations. Why this should be so is not explained in the Sanitary Commissioner's report, as the provision of mosquito curtains is essentially the greatest prophylactic factor known in the prevention of infection by the mosquito. Operations against mosquitoes by such means as can be accomplished by mosquito brigades have been in practice in nearly all stations in the plains for several years. The Sanitary Commissioner, commenting on the value of these operations, states: "In most stations they are thoroughly carried out, but it is the general opinion of medical officers that by limited measures of this kind an appreciable reduction of the number of anopheline mosquitoes is not produced." In one or two stations measures of a more extensive kind have been undertaken, notably in Lahore Cantonment, in regard to which the results obtained are being examined by a committee appointed by the Government of India.

Kala-Azar.

Under the heading of "Kala-azar," which appears for the first time in the official returns for 1908, 4 cases of this disease with 1 death are recorded amongst European-serving soldiers. The cases occurred at Madras, Wellington, Jhansi, and Jubbulpore. In two of the cases the diagnosis was confirmed by finding the Leishman-Donovan parasites in blood taken from the spleen or the liver.

With regard to enteric fever, 1001 cases were reported during the year, 190 of them proving fatal, as compared with 910 attacks and 192 deaths in 1907. The admission ratios for 1908 were 14·5 per 1000, as compared with 13·1 per 1000 for 1907, and the death-rate was 2·76 per 1000, as compared with 2·77 per 1000 in 1907. Taking into account the cases that remained under treatment at the end of 1907, the case mortality during 1908 was only 17 per cent., which compares favourably with the figures for males of approximately the same ages under treatment in hospitals in England. Although the number of cases recorded as having occurred among the troops of the Bazar Valley and Mohmand Field Forces is small, the influence of these expeditions is, perhaps, seen in the high incidence of the disease among the troops of the Peshawar Division, from which the fighting forces were drawn. The inference is that the troops which formed part of the two expeditionary forces, although not suffering from enteric fever to any marked extent while in the field (which was only for a few weeks), on their return to cantonments were either so debilitated that they developed the disease, or else were infected in the field and incubated the disease, which broke out on their return.

Enteric Fever.

The military cantonments in which the largest numbers of cases of enteric fever occurred were Rawalpindi (93) Secunderabad (80), Meerut (54), Peshawar (52), Bangalore (43), and Quetta (42). As usual, the reports upon enteric fever compiled by officers of the Royal Army Medical Corps in charge of station hospitals are concerned largely with the accounts of the inquiries made to ascertain the source and mode of infection, and it is regretted that these inquiries failed in the great majority of instances to yield a definite result. No outbreak was conclusively traced to water during the year, but it was suggested as the probable source of infection of patients admitted to hospital at Sitapur, Agra, Chakrata, Allahabad, Purandhar, Sialkot, and some other stations. At Agra it was reported that the B. coli communis was found in the municipal drinking water and that the presence of the B. typhosus was suspected. Milk was suggested as being possibly the cause of cases at Rawalpindi, Multan, and Shwebo, ice-creams at Karachi, lemonade at Allahabad, and soda-water at Sialkot. Food taken in eating-houses outside cantonment limits was thought to be the infecting agent at Calcutta, Madras, and Quetta, and, as usual, a number of cases were attributed to articles of food or drink obtained in native bazaars. Infection through the medium of latrines was considered the most likely cause at Ahmednagar and Subathu, and infective clothing was suspected with good reason at Kirkee. Amongst the European and native troops about 40 cases were contracted on the Bazar Valley expedition, the limited area of the camps, their proximity to insanitary native villages, fouled ground, bad water, the prevalence of flies and of dust, and the incessant toil inseparable from active service being regarded as the important factors concerned. In many stations flies and dust were considered to be contributing factors.

In some stations attempts were made to discover the human host harbouring typhoid bacilli and infecting media as carriers. Successful results attending this important method of inquiry were attained at Wellington, Sialkot,

Mhow, Jubbulpore, Erinpura, and some other stations. At Wellington the search was carried out with great thoroughness by the bacteriological examination of the excreta of all convalescents three times a week, and by this means one man was found to have chronic typhoid bacilluria 13 months after his attack of enteric fever. At Sialkot the investigations revealed the grave danger which may arise from the employment of native Indian cooks in the kitchens which prepare the food for British troops. A servant in the officers' mess who had previously been employed as an assistant cook was found to have typhoid bacilluria, and two cooks of one of the squadrons of a cavalry regiment were found to be affected with the same condition. As a result of these discoveries all natives applying for the post of cook were examined, and by this means another carrier was detected. At Mhow, Jubbulpore, and Erinpura the investigations were limited to an examination of the blood of suspected persons by the Widal test, and although a person whose blood gives a positive reaction with this test may not necessarily be a carrier, the method affords a good clue for the more laborious method of investigation—namely, the examination of the excreta. At Mhow the blood examination of three natives employed in the regimental institutes (two in the coffee-shop and one in the bakery) gave positive reactions with Widal's test, and at Erinpura the blood of one of the servants employed in the officers' mess, where three officers were thought to have contracted enteric fever, was found to give a positive reaction. At Jubbulpore one European and three native servants were dismissed on the grounds of a positive reaction with the test. Many other instances are quoted. Evidence is also recorded of the danger of infection from patients during the acute stage of enteric fever; this danger is recognised at all stations, but despite the careful precautions adopted three orderlies nursing patients suffering from enteric fever contracted the disease at Rawalpindi, and four nursing orderlies became infected in a similar manner at different other stations.

One of the most interesting and ably written portions of the Sanitary Commissioner's report is that in which he presents a summary of recent work done and papers published by continental and other observers relating to the epidemiology of enteric fever. In the report under review there is compiled the usual interesting summary of current literature regarding enteric fever from German and other sources which will prove most interesting reading to the many practitioners to whom this subject cannot fail to be of importance. The question of bacilli carriers is lucidly described; the remarks embodied, translated from German sources, are worthy of mention.

General Remarks: Venereal Diseases.

Passing next to consider the question of the prevalence of tuberculous disease of the lungs we find that no less than 93 cases with 16 deaths occurred in the British forces serving in India during the year. This disease has received considerable attention during recent years in view of its increasing prevalence amongst the native population. Dysentery was more prevalent among all classes of people in India than in 1907, and the admission- and death-rates amongst European troops rose from 11·7 and 0·33 per 1000 respectively to 14·4 and 0·42. Abscess of the liver was considerably less prevalent, the admissions to hospital being 115 and the deaths 55, as compared with 165 and 70 respectively in the previous year. As regards venereal diseases, the fall in the rates relating to these has been one of the most remarkable features of the medical statistics of the British army during past years and can be attributed to the efforts of the officers of the army, combatant and medical, from the Commander-in-chief downwards, to stamp out vice and make the men's lives attractive. The various Church bodies and the Royal Army Temperance Association have contributed to these ends also, and with a higher moral tone among the rank and file of the army, the admission rates fell in 1908 to 69·6 per 1000, which is the lowest rate on record. Of all the honours deservedly won by Lord Kitchener during his long and arduous career in the army there is none for which he will deserve the thanks of the nation better than his strenuous efforts, which have proved so successful, during his term of office in India to reduce the prevalence of venereal disease in the army of India.

(To be continued.)

THE PREVENTION OF INFANT MORTALITY IN HESSE.

THE prevention of infant mortality is a problem that is at present engaging the attention of practically every country that has at last awakened to a realisation of the importance of this question and its bearing on the national welfare. In this connexion it is to be regretted that the Pure Milk Bill had to be sacrificed owing to political exigencies, but even the fact that a Government measure of this nature has been elaborated may be taken as a promising sign that the State has decided to actively endorse a policy to which the nation's attention was first drawn by the step taken some time ago by a mayor of Huddersfield.

In spite of the many social laws with which our Teuton cousins have set an example, the high rate of mortality during the first year of life in Germany has led to a serious consideration of the factors responsible for so deplorable a state of affairs, and two measures recently adopted in the Grand Duchy of Hesse as the outcome of deliberations on the subject are worthy of being chronicled. The first of these takes the form of a leaflet which has been extensively distributed to all the sick-club organisations of the Grand Duchy and prominently displayed in order to be brought to the notice of all club members. A translation of the wording of this admonition will best illustrate the aim advanced by its promoters.

Protection of Mothers and Nurslings by the Sick Clubs.

In Germany 400,000 children die yearly before attaining the age of 1 year; this represents 20 per cent. of all children born alive. This high rate of mortality does not imply a selection of the weakest, leaving behind a more resistant stock; on the contrary, the causes of this high death-rate also determine a deterioration of the constitution in the survivors.

A timely protection of the child guarantees to the adult the capacity of resisting harmful influences of all kinds.

The preservation of the infant and the improvement of its constitution is dependent upon the mother's care of herself before and after child-birth, and upon her provision of the child with natural nourishment and motherly attention.

Every week, every day during which natural nourishment is prolonged is of incalculable value to the child.

The women of our people are largely prevented from taking proper care of themselves and exercising the natural duty of suckling owing to necessity and the obligation of obtaining a livelihood by outside work.

The most effective protection of the infant is assured by strengthening the mother and furnishing the child with natural nourishment and care for the longest possible period.

To effect this protection it is a *sine qud non* to grant material assistance to the mother.

By the terms of the Sickness Insurance Law the sick clubs are entrusted with the duty of providing this assistance, as they are required to grant sick pay to their female members for a period of six weeks during child-birth. This compulsory assistance can only be regarded as the minimum limit, both as far as the amount and the persons to which it is applicable are concerned. At present the law enables the sick-club to extend its benefits by including a provision for the child, and the proposed Imperial Insurance Bill even goes further.

In contemplating an enlargement of the benefits to be granted to members every sick club should first of all provide for an extension of the protection afforded to mothers and infants.

According to the laws at present in force this can be effected by:

(*a*) Granting sick pay during gravidity, and free service of midwife and doctor to female members during child-bearing.

(*b*) The inclusion of members of the insured person's family in the sick club, in order to guarantee prompt medical attendance to the infant in the case of illness. At least the women in childbed and infants should be included.

(*c*) Granting sick pay to pregnant women during incapacity for work, further free medical and midwife attendance for the treatment of troubles during pregnancy.

The interests of the female members of the sick clubs and their children are best safeguarded by women, and it would be desirable to engage the services of women as sick club inspectors for such purposes.

The protection of the pregnant women is closely allied with the improvement of the bodily strength and soundness of our nation.

The sick-clubs are in a position to actively coöperate towards the attainment of this aim. In doing so they work for their own profit, for the improvement of the whole bodily constitution of the people implies an increase in the reserve funds of the sick-clubs.

This leaflet is issued by the Grand Ducal Board for the Protection of Mothers and Infants in Hesse.

The second step adopted in the same country for the identical object is of a local character and has been adopted by the municipality of Darmstadt, the capital of the Grand Duchy. The decision arrived at by the town council and brought to the citizens' notice by insertion in the local papers will convey an idea of the motives underlying so humane a measure. The town council advertised as follows:—"During the hot summer months the mortality among infants, especially of those artificially fed, increases regularly in a marked manner. According to the unanimous opinion

of medical men the principal cause of this phenomenon is to be found in the partaking of tainted milk, which causes gastric and intestinal troubles in the children. With the consent of the town council, and with the aid of a grant from the municipal funds, we have adopted a measure designed to provide the poorer inhabitants of Darmstadt during the dangerous summer months with irreproachable milk." For the purpose of carrying out the plans of the council a dairy, which is under the supervision of the municipal authorities, is empowered to supply sterilised, boiled, and raw pure milk to persons who have obtained a permit after application to the municipal authorities for a period not exceeding four months, beginning with June 1st of the year. The sterilised milk is supplied in the following qualities :—

		Price per bottle.
No. I.	for infants aged 1 month ½ milk and ½ water	¼d.
No. II.	,, ,, ,, 2-4 months ½ ,, ,, ½ ,, ...	⅜d.
No. III.	,, ,, ,, 4-6 ,, ¾ ,, ,, ¼ ,, ...	½d.
No. IV.	,, ,, ,, over 6 ,, milk only	¾d.

(The price in German currency is 2, 3, 4, and 6 pfennigs; 8 pfennigs = 1d.)

This sterilised milk is supplied in bottles of 200 c.c. and only requires to be warmed by placing the bottle in warm water, and after removing the cap the well-cleansed teat should be attached. It is expressly stated that the milk should not be warmed in any other receptacle.

The purified boiled milk is supplied as follows :—

1000 c.c.	500 c.c.	200 c.c.
3d.	1½d.	¾d.

The purified raw milk is distributed in bottles of 1000 c.c. and 500 c.c. at charges of slightly less than 3d. and 1½d. Not more than six bottles of sterilised milk or 1500 c.c. of purified raw milk will be supplied daily to each person. An extra charge of ¼d. for each bottle of sterilised milk, or ¾d. per 1000 c.c. of purified boiled milk, and ¼d. per 1000 c.c. of raw milk will be levied should more be required. The milk is delivered at the person's door and must be paid for on delivery, and the dairy is entitled to compensation in the event of bottles or caps not being returned.

It might be assumed that so humane a scheme, free from irksome restrictions, as it is expressly open to all the "less well-to-do" citizens, and demanding no trouble on the part of its adherents, as the milk is even delivered at their own door, would be eagerly adopted by a large number. It is disheartening to record, and yet so consistent with human nature all the world over, that but few have taken the trouble to avail themselves of this benefit, but prefer to raise their progeny on all kinds of patent foods if not on worse and more harmful forms of nourishment, and even those who participate show their gratitude by voicing varied supposed grievances and preposterous claims. The best intentions of the social reformer are unfortunately only too often negatived by opposition among those for whose welfare he labours.

As the Grand Ducal Board for the Protection of Mothers and Infants recognises that the midwives are in a position actively to coöperate in the furtherance of the aims that have led to the creation of this body, it has decided to publish a special journal, to appear every two months, and devoted to subjects bearing on this question. This publication will be delivered free of charge to all midwives who belong to the different district associations, and in order to ensure their taking an effective interest in the scheme the board proposes to grant them special favours. Several leading physicians have promised contributions to "Mutter und Kind," as the new journal will be entitled.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 77 of the largest English towns 10,076 births and 4142 deaths were registered during the week ending May 28th. The annual rate of mortality in these towns, which had been 13·1, 13·8, and 12·4 per 1000 in the three preceding weeks, rose to 12·7 in the week under notice. During the first eight weeks of the current quarter the annual death-rate in these towns averaged 13·6 per 1000, while in London during the same period the rate did not exceed 13·2 per 1000. The lowest recorded annual rates of mortality during last week in these 77 towns were 5·1 in West Hartlepool, 5·5 in Walthamstow and in Ipswich, and 7·0 in East Ham and in Leyton; the rates in the other large towns ranged upwards, however, to 17·9 in Rochdale, 19·9 in Burton-on-Trent, 25·4 in Dewsbury, and 25·6 in Merthyr Tydfil. In London last week the recorded death-rate did not exceed 11·8 per 1000. The 4142 deaths registered last week in the 77 towns showed an increase of 99 on the low number returned in the previous week, and included 424 which were referred to the principal epidemic diseases, against 407 and 400 in the two preceding weeks; of these 424 deaths, 159 resulted from whooping-cough, 157 from measles, 49 from diarrhœa, 22 from scarlet fever, 20 from diphtheria, and 17 from enteric fever, but not one from small-pox. The mean annual rate of mortality in the 77 towns last week from these epidemic diseases was equal to 1·3 per 1000, against 1·3 and 1·2 in the two preceding weeks. No death from any of these epidemic diseases was registered last week in Derby, Hornsey, King's Norton, Reading, or in nine other smaller towns; the annual death-rates therefrom ranged upwards, however, to 3·3 in Oldham, 4·1 in Dewsbury, 4·7 in Burton-on-Trent, and 8·5 in Merthyr Tydfil. The fatal cases of whooping-cough in the 77 towns, which had been 138 and 154 in the two preceding weeks, further rose to 159 last week; they caused annual rates equal to 1·5 in Manchester, 2·1 in Wallasey, and 2·9 in Oldham. The 157 deaths from measles showed an increase compared with the numbers in the two preceding weeks; the highest death-rates from this disease during the week were 1·9 in Blackburn, 2·0 in Dewsbury, 3·8 in Burton-on-Trent, and 7·9 in Merthyr Tydfil. The deaths attributed to diarrhœa which had been 49 and 32 in the two preceding weeks, rose again to 49 last week. The 22 fatal cases of scarlet fever showed a slight decline compared with recent weekly numbers, and included 5 deaths in London and its suburban districts. Only 20 deaths were referred to diphtheria last week, against 37 in each of the two preceding weeks. The 17 deaths from enteric fever included 3 returned in Bradford and 2 in London. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily declined from 2810 to 1476 in the 32 preceding weeks, further fell to 1445 during the week under notice; 194 new cases of this disease were admitted to these hospitals during last week, against 177 and 190 in the two preceding weeks. Of the 1107 deaths registered in London during the week under notice 162 were referred to pneumonia and other diseases of the respiratory system, showing a substantial decline from the numbers returned in recent weeks; these 162 deaths were 59 below the corrected average number in the corresponding week of the five years 1905–09. The causes of 38, or 0·9 per cent., of the deaths registered in the 77 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death registered during the week were duly certified in Manchester, Leeds, Sheffield, Bristol, and in 49 other smaller towns; the 24 uncertified causes of death in the 77 towns last week included 6 in Birmingham and 3 both in Liverpool and in St. Helens.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 969 births and 506 deaths were registered during the week ending May 28th. The annual rate of mortality in these towns, which had been equal to 15·3 and 15·5 per 1000 in the two preceding weeks, declined to 14·0 in the week under notice. During the first eight weeks of the current quarter the death-rate in these towns averaged 16·4 per 1000, and exceeded by 2·8 the mean rate during the same period in the 77 large English towns. The annual death-rates last week in these eight Scotch towns ranged from 9·3 and 9·8 in Aberdeen and in Perth, to 17·0 in Greenock and 23·0 in Dundee. The 506 deaths from all causes in the eight towns during last week showed a decrease of 56 from the number in the previous week, and included 62 which were referred to the principal epidemic diseases, against 80 and 63 in the two preceding weeks. These deaths were equal to an annual rate of 1·7 per 1000; the mean death-rate from the same diseases in the 77 English towns last week did not exceed 1·3 per 1000. These 62 deaths in the Scotch towns last week included 33 from

measles, 15 from diarrhœa, 5 from whooping-cough, 4 from scarlet fever, 4 from diphtheria, and 1 from enteric fever, but not one from small-pox. The fatal cases of measles in the eight towns, which had declined from 52 to 41 during the three preceding weeks, further declined last week to 33, and included 19 in Dundee, 9 in Glasgow, and 2 in Edinburgh. The 15 deaths attributed to diarrhœa showed but slight variation from the numbers recorded in recent weeks; 7 deaths were returned in Glasgow and 6 in Dundee. Two of the deaths from scarlet fever, and 2 of the 4 fatal cases of diphtheria were recorded in Glasgow; the death from enteric fever also occurred in Glasgow. The deaths in the eight towns referred to diseases of the respiratory system, which had been 99 and 98 in the two preceding weeks, declined to 80 last week, and were 14 below the number in the corresponding week of last year. The causes of 9, or 1·8 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·9 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 727 births and 467 deaths were registered during the week ending May 28th. The mean annual rate of mortality in these towns, which had been equal to 20·1, 21·3, and 19·5 per 1000 in the three preceding weeks, rose to 21·1 in the week under notice. During the first eight weeks of the current quarter the annual death-rate in these Irish towns averaged 21·6 per 1000, whereas the mean rate during the same period did not exceed 13·6 in the 77 large English towns and 16·4 in the eight principal Scotch towns. The annual death-rate during last week was equal to 19·5 in Dublin, 23·5 in Belfast, 26·7 in Cork, 24·0 in Londonderry, 24·6 in Limerick, and 21·4 in Waterford; the mean annual death-rate last week in the 16 smallest of these Irish town districts was equal to 16·1 per 1000. The 467 deaths from all causes in the 22 town districts last week showed an increase of 36 over the number recorded in the previous week, and included 50 which were referred to the principal epidemic diseases, against 41 and 59 in the two preceding weeks; these deaths were equal to an annual rate of 2·3 per 1000; in the 77 English towns the mean rate last week from the same diseases did not exceed 1·3 per 1000, while in the eight Scotch towns it was equal to 1·7. The 50 deaths from these diseases in the Irish towns last week included 33 from measles, 8 from whooping-cough, 5 from diarrhœa, 2 from diphtheria, 1 from scarlet fever, and 1 from enteric fever, but not one from small-pox. The fatal cases of measles, which had increased from 9 to 45 in the five preceding weeks, declined to 33 last week, all of which were recorded in Belfast. The 8 deaths from whooping-cough showed but slight variation from recent weekly numbers, and included 5 deaths in Belfast and 2 in Portadown. Of the 5 deaths attributed to diarrhœa, 2 were registered in Dublin and 2 in Belfast. The fatal cases of diphtheria occurred in Belfast and in Limerick. The fatal case of scarlet fever was recorded in Belfast and that of enteric fever in Dublin. The deaths in the 22 towns referred to pneumonia and other diseases of the respiratory system, which had been 120 and 84 in the two preceding weeks, rose to 90 last week. The causes of 12, or 2·6 per cent., of the deaths registered in the Irish towns last week were not certified; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·9 per cent., and in the eight principal Scotch towns it was equal to 1·8 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned qualified candidates for the Naval Medical Service have been appointed Surgeons in His Majesty's Fleet:—William Herbert King, Francis Cooke Alton, Horace Elliot Rose Stephens, Douglas Ashley Mitchell, John Scott Ward, Charles Fox Octavius Sankey, David Horgan, Robert Nicholas William Walter Biddulph, Ernest Mac Ewan, Dermot Loughlin, Maurice Charles Mason, Matthew Fitzjames Caldwell, Arthur Holmes Joy, Alexander Stephen Paterson, and Ernest Lacey Markham (dated May 6th, 1910).

The following appointments are notified:—Staff-Surgeons: W. H. B. Shewell to the *Assistance;* and G. S. Davidge to Gibraltar Hospital. Surgeons: C. G. Sprague to the *St. George;* A. W. Iredell to the *Bulwark;* J. H. McDowall to the *Espiegle;* P. D. McI. Campbell to the *Victory*, additional, for disposal; and T. E. Blunt, L. Warren, and J. M. Gordon to Plymouth Hospital.

ROYAL ARMY MEDICAL CORPS.

Surgeon-General J. G. MacNeece has been appointed Principal Medical Officer of the Eighth (Lucknow) Division, vice Surgeon-General P. M. Ellis, retired. Lieutenant-Colonel W. J. Baker has arrived home from Egypt on leave. Lieutenant-Colonel C. A. Lane has been transferred from the Southern to the Eastern Command, and appointed to the medical charge of the Military Hospital at Hounslow. Major W. P. Gwynn, from Karachi, has been posted to Quetta. Major M. Swabey has arrived home from India on leave. Captain W. Bennett, from Cork, and Captain G. F. Sheehan, from Dublin, have embarked for a tour of service in India. Captain A. C. Osburn, from Mandalay, has been appointed to the Eastern Command, and posted to Sheerness for duty. Captain H. O. M. Beadnell has been granted six months' leave from India. Captain F. H. Noke has been posted to the Aldershot Command. Captain T. E. Fielding has joined London District for duty. Captain J. G. Churton, from Aldershot, has been posted to Peshawar. Captain A. F. Weston has been transferred from Cosham to the Royal Victoria Hospital at Netley. Lieutenant M. O. Wilson, from Karachi, has been posted to Quetta. Lieutenant W. B. Purdon has been transferred from Rangoon to Maymyo. Lieutenant J. E. Ellcome, from Tregantle, and Lieutenant R. M. Dickson, from Glasgow, have embarked for a tour of service in India.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel D. T. Lane, Civil Surgeon at Sialkot, has been appointed Civil Surgeon of Murree. Lieutenant-Colonel H. Hendley has been granted two and a half months' leave on medical certificate by the Secretary of State for India, in extension of his combined leave. Major P. Carr-White has been appointed Agency Surgeon to the Kotah and Jhalwar Districts. Major S. A. Harriss, Deputy Sanitary Commissioner of the United Provinces, has been selected to officiate as Sanitary Commissioner of Burma during the absence on leave of Major C. E. Williams. Major P. St. C. More, Civil Surgeon of Attock, has been placed on special duty in the United Provinces and Bengal. Major S. Hunt has been granted seven months' leave home from India. Captain W. Mc M. Pearson, Captain W. S. McGillivray, and Captain H. Boulton have arrived home on leave. Captain W. M. Thomson has been granted eight months' leave from India. Captain J. Mac G. Skinner has been posted to Madras Presidency. The services of Captain H. B. Drake, Officiating Deputy Assay Master, Bombay, have been replaced at the disposal of His Excellency the Commander-in-Chief in India. Captain C. E. Southon, District Plague Medical Officer, Ludhiana, has been granted study leave combined with furlough home from India for 20 months. Captain S. H. Lee-Abbott, Civil Surgeon at Dera Ghazi Khan, has been transferred for duty to Dalhousie. Captain A. K. Lauddie, Civil Surgeon at Karnal, has been appointed Civil Surgeon at Dera Ghazi Khan. Lieutenant H. M. Inman has arrived home on leave.

TERRITORIAL FORCE.

Yeomanry.

Montgomeryshire: Surgeon-Captain Francis E. Marston resigns his commission (dated April 4th, 1910).

Royal Army Medical Corps.

1st East Lancashire Field Ambulance: Captain Gordon William Fitzgerald, from the 3rd East Lancashire Field Ambulance, Royal Army Medical Corps, to be Captain (dated May 14th, 1910). Albert Ramsbottom (late Captain 2nd Western General Hospital, Royal Army Medical Corps) to be Lieutenant (dated May 14th, 1910).

3rd East Lancashire Field Ambulance: Lieutenant Robert

Burnet, from the list of officers attached to Units other than Medical Units, to be Lieutenant (dated May 14th, 1910). Edward Harvie Cox, to be Lieutenant (dated May 14th, 1910).

1st Welsh Field Ambulance: Major Thomas L. K. Davies resigns his commission and is granted permission to retain his rank and to wear the prescribed uniform (dated April 30th, 1910).

2nd Western General Hospital: Captain Albert Ramsbottom resigns his commission (dated May 14th, 1910).

For attachment to Units other than Medical Units.—Edward Oscar Libbey to be Lieutenant (dated March 23rd, 1910). Donald Gray MacGill to be Lieutenant (dated April 1st, 1910). Captain Walter Reginald Norman Smithard, from the 1st East Lancashire Field Ambulance, Royal Army Medical Corps, to be Captain (dated May 2nd, 1910).

Attached to Units other than Medical Units.—Lieutenant Frederic R. Sutton resigns his commission (dated April 13th, 1910). Lieutenant Henry Smurthwaite resigns his commission (dated April 22nd, 1910).

Colonel Sir J. R. A. Clark, Bart., Unattached List R.A.M.C. (Territorial), has been selected by the Army Council to inspect the Territorial Medical Units in each command.

DEATHS IN THE SERVICES.

Fleet-Surgeon Joseph Cudlip Wood, R.N., at Rosevine Portscatho, recently. He entered the service as surgeon in 1891, became staff-surgeon in 1899, and fleet-surgeon in 1907.

THE BRITISH RED CROSS SOCIETY.

At a meeting of the Devonshire branch of the Red Cross Society held on May 25th at Exeter it was announced that there were now 771 members and associates of the Red Cross Society in the county, guaranteeing £1800 if required on the outbreak of war, and that the annual subscriptions now amounted to £125. The expenditure since May, 1907, to obtain this result was under £30.

Mr. H. Mainwaring Holt, M.R.C.S. Eng., L.S.A., D.P.H., has recently been presented by the members of the first aid and nursing classes at Norton, Malton, with a case of surgical instruments as a token of their appreciation of his kindly interest in their work. In thanking the classes for their gift Mr. Holt referred to a scheme of competition which he hoped to introduce among the various nursing classes. A day could be set apart in the open, he said, when perhaps some of the boy scouts would act as patients. In that way the Red Cross Society and nursing would be one living whole. At present the Red Cross was practically dead as a functionary body, but alive as an organising body.

THE ARMY MEDICAL OFFICERS' WIDOWS FUND.

The annual meeting of the supporters of this fund was held at the Royal United Service Institution, Whitehall, on May 24th, when Deputy Surgeon-General W. G. Don presided. The committee in its report expressed its regret at the resignation of the President, Surgeon-General Sir Alfred Keogh, and recorded its high appreciation of his services during his term of office. The number of members who joined the Fund during 1909 was 15, and since the beginning of the present year 11 new members had joined. At the end of 1909 there were 131 members and 75 annuitants. The following officers were elected: Surgeon-General W. L. Gubbins, Director-General of the Army Medical Service, President; Surgeon-General W. S. M. Price, an additional vice-president; Lieutenant-Colonel A. F. S. Clarke a trustee, vice Deputy Surgeon-General C. A. Innes who has resigned. Surgeon-General Sir Charles Cuffe and Brevet Lieutenant-Colonel Sir William B. Leishman were added to the committee.

THE BRITISH ANTARCTIC EXPEDITION.

Surgeon G. M. Levick, R.N., and Surgeon E. L. Atkinson, R.N., have been officially appointed to the British Antarctic Expedition. The *Terra Nova*, Captain Scott's ship, sailed from the Thames on June 1st.

The department of the Medical Director-General of the Navy has removed from 18, Victoria-street, Westminster, to new quarters in the Admiralty, Whitehall.

A good service pension of £100 a year has been conferred on Surgeon-General G. J. H. Evatt, C.B., A.M.S., retired.

Correspondence.

"Audi alteram partem."

THE MIDWIVES BILL AND POOR-LAW RELIEF.

To the Editor of THE LANCET.

SIR,—What your anonymous correspondent clearly points out regarding the accumulating difficulties of medical practice in poor districts must surely be patent to all unbiased observers. Look where we will, we find the incomes of medical men steadily diminishing. The son, better educated and more able to treat disease than his father, can earn but a small proportion of the income formerly made by his father. Why is this? No doubt, increased competition among ourselves is one of the causes, but in my opinion it is a factor that sinks into insignificance in comparison with those of the kind enumerated by "One who believes in Parental Responsibility."

As good citizens, we might have some consolation in the thought that the nation was the better for all the mischief brought upon our profession; that the principle of universal State provision, though destructive to us, yet greatly advances the public welfare. In my opinion, all the facts point the other way. Take the universal provision of education. Only last week Lord Justice Buckley in the Court of Appeal said: "This action bears sad testimony to the legislation which discourages independence and self-reliance, and leads the class it benefits—or, as I should prefer to put it, is supposed to benefit—into the belief that they are entitled to pass all their responsibilities and risks upon others. Gratuitous education and conveyance provided at the public cost to take children to school result, not in gratitude, but in discontent with everything that is provided."

Sir Dyce Duckworth, speaking at Lewisham some time ago of "the many demoralising influences that were at work," said that our elementary schools had brought hooligans among us to an alarming degree.

Mr. Roosevelt recently at a large public meeting said "that the deadening effect of the adoption of a logical Socialistic system could not be overstated; it would spell sheer destruction; it would produce grosser wrongs and outrage, fouler immorality than any existing system."

Sir William Collins on May 24th, at the meeting of the Medico-Legal Society, commenting on some of my remarks on retrograde legislation—which Lord Justice Buckley seems to recognise—said that school dinners and school medical attendance were only a logical extension of the Elementary Education Acts. There can be no doubt that these Acts are part of a Socialistic system, and school dinners and medical attendance are logical extensions of the same, and it is impossible to say where such extensions will end. Possibly Sir William Collins does not believe in Mr. Roosevelt's views as to the results of the adoption of a logical Socialistic system. The universal provision of services by the State seems to me the keystone of the arch of a "logical and extreme Socialistic system," such as Mr. Roosevelt condemns. This principle at present is threatening the ruin of the profession of medicine, but it will not stop there. It is easy to see a logical extension in many other directions.

Your annotation on the Salaries of Whole-time Medical Officers of Health affords another example of the mischievous effect of this principle on the medical profession. To a State service of special officers to safeguard the public welfare in matters of sanitation few could object, and so long as many of these posts were held by part-time men, who are interested on their own account in maintaining parental responsibility, little harm would be likely to be brought on the profession generally. But when a policy of whole-time officers is followed it becomes necessary to find more work for these officials than the attending to mere matters of public health in the ordinary meaning of the term. Other duties have to be found, and the principle of the universal provision of State services answers admirably for that purpose. If the maintenance of parental responsibility stands in the way, so much the worse for parental responsibility. But it must not be forgotten that it is not only the

medical profession that suffers but in reality the whole nation.

What is being done at Walsall is only typical of what is taking place all over the country, and it is pitiable to think how much harm will not unlikely be done to the general practitioners of the country by the multiplication of these whole-time officials, who, in order to have sufficient work to justify their existence, must undertake duties that in the not remote future will seriously threaten the little private practice that still remains to their brethren endeavouring to gain a living in poor districts.

I am, Sir, yours faithfully,

Hackney-road, N.E., May 28th, 1910. MAJOR GREENWOOD.

THE OPERATION FOR CLEFT PALATE.

To the Editor of THE LANCET.

SIR,—The remarks of Mr. Thomas H. Kellock on this subject, which appear in THE LANCET of this week, raise a question of considerable interest and of great importance. Mr. Kellock tells us that he had recently under his care two children who during infancy had been operated upon for cleft palate. "It is true that in both of them the cleft had been closed over, but the palate that had been so fashioned was a most inefficient one, the soft palate was very short in an antero-posterior direction and terminated posteriorly in an almost straight transverse line, the movements of the soft palate were almost absent ..... As far as speech was concerned the result was very poor, and in one case, that of a child aged about 9 years, it was little, if anything, better than in a case where no operation had ever been performed."

The unsatisfactory results in these two cases may, of course, be exceptional, but those of us who delay operating upon the palate until the child is about 2 years of age believe that if an operation is performed during infancy it must be at the expense of the soft palate. The chief object in closing a cleft palate is to render the powers of speech more perfect than they otherwise could be, and a well-formed and freely moveable soft palate is the all-important factor in obtaining a good result in this respect.

During the past ten years the early operation for cleft palate has been very frequently practised by surgeons in London, due no doubt largely to the fact that the operation has been extensively advertised, and the attention of the profession and of the public directed to it. What are the after-results as regards the powers of speech when a cleft palate has been closed during infancy? The answer is entirely a question of evidence; and surely, Sir, there must be plenty of evidence at hand in London. I would suggest that it would be extremely interesting if, at the meeting of the British Medical Association in July next, London surgeons who so strongly advocate this early operation should bring forward some of their cases and so let those of us who are sceptical be convinced by hearing the children speak.

I am, Sir, yours faithfully,

Liverpool, May 28th, 1910. R. W. MURRAY.

HOSPITALS IN SHIPS AT SEA.

To the Editor of THE LANCET.

SIR,—In your Annotations of last week I read with great interest your *résumé* of the paper on the Hospital Establishment of Passenger Ships, by Dr. Dupuy and Dr. Villejean, read before the International Medical Congress held at Budapest. As the subject is one in which I have taken considerable interest it is with great satisfaction that I note that it is at length meeting that recognition from the medical profession that its importance merits.

In 1906 I pointed out what steps I considered necessary to be taken in order to ensure efficient reform in the medical, nursing, and hospital arrangements of passenger ships carrying large numbers of emigrants, and I venture to enclose you a reprint of my letter to the *British Medical Journal* of July 21st, 1906, giving the details of the reforms that I then advocated. That my suggestions were not considered unreasonable by the medical and lay press was shown by the flattering notices that they received in the *Tribune* and *Hospital and Nursing Mirror* of this country, and the lengthy extracts from my letter that appeared in the English papers of Rio, Montevideo, and Buenos Aires, and also in some Australian papers.

Although for the last five years laboratory work on land rather than surgery at sea has fallen to my lot, still I should like to add my word on behalf of the sick emigrant, whose treatment I then considered an anachronism and a disgrace to the hygienic and humanitarian principles of modern civilisation.

I am, Sir, yours faithfully,

HUGH WANSEY BAYLY.

Brook-street, Grosvenor-square, W., May 30th, 1910.

MEASLES AND THE POST-OFFICE AUTHORITIES.

To the Editor of THE LANCET.

SIR,—I was interested in reading an annotation in your issue of May 14th on the question of how measles is spread, but I must say that my experience of over 20 years in general practice does not enable me to accept the teaching laid down. As your readers may remember, the medical officer of health to the Brixham urban district council advised the Post Office authorities to withdraw a postman from his duties on the ground that as his wife had contracted measles he was carrying about the infection wherever he went and thus was spreading the disease. I know that our text-books nearly all contain this teaching, and the public generally have an idea that the infectious diseases can be transmitted in all sorts of strange ways, but has not the time come for some authoritative statement to be made in this matter? Is there not a danger of our believing time-honoured statements which, when examined by the light of scientific facts, will not be so generally accepted?

With reference to measles, for instance, I have never heard of an authentic case where a medical man had carried the infection to any member of his family. For some years past I have asked as many medical men as possible if any of them could remember ever having been the means of carrying the infection to any of his family, and I have been invariably answered in the negative. I am informed that nurses who are in our isolation hospitals never take the infection with them when they visit their friends. Dr. F. G. Crookshank, medical officer of health of Barnes, actually employs the same nurse for the different infectious diseases, the patients being separated by glass screens, but he has never found an instance where the nurse has conveyed one disease to a patient suffering from a different disease (see THE LANCET, Feb. 19th, 1910, p. 477). All these instances, and I could cite more, go to show that it is not the experience of those who have to do most with these infectious diseases that these diseases are carried about in this manner, but personal contact is absolutely essential and personal contact alone.

The fact is, if you stop the postman from his daily round because he has measles at home, you might as well stop the members of our profession from pursuing their calling also and brand them as carriers of infection wherever they go. But are they? I certainly do not believe it for a moment. I have not yet heard or seen any facts which would warrant our acceptance of such a statement, but I fear there is a good deal of prejudice left in our profession and a disinclination to let go old beliefs even if their fallacy is shown. It is really ridiculous, if it were not serious, to notice how people are boycotted by their friends and how many are interfered with in their daily avocation because there happens to be in their homes some case of infectious disease. Let us by all means properly isolate these diseases for as long a time as we may think right, but do not let us interfere unnecessarily and without any good purpose with the calling of bread-winners or the convenience of the public.

I am, Sir, yours faithfully,

Wimbledon-hill, S.W., May 28th, 1910. S. R. COLLIER.

THE LATE DR. E. CRESSWELL BABER.

To the Editor of THE LANCET.

SIR,—The obituary notice of the late Dr. E. Cresswell Baber, though giving a sympathetic and full account of his life history, must seem to his friends, who are many, to be susceptible of a little amplification. Those who as his fellow specialists came most closely in contact with him are those who miss him most, and among the whole group there is probably not one who will be more missed. The character

of the man claimed for him the respect as well as the affectionate regard of all his associates. Behind the somewhat cynical manner of speaking which the casual observer might misinterpret, there lurked a depth of warm and genuine feeling which at once impressed those who had the privilege of enjoying the slightest intimacy with him. Shrewd and unerring in his judgment of men and action, nothing questionable, tricky, or paltry escaped his instant detection. In his apparently cynical way he was able to indicate his recognition of the weak point while treating it with the gentle smile which was prompted by his infinite indulgence for weaknesses in his fellow men, which he would not have permitted in himself. While the quickest to perceive their shortcomings, he was ever ready to recognise and acknowledge whatever was good even in those whom it was fashionable to decry.

Such being his intellectual and moral qualities, his social side was one of great charm. He took delight in giving and accepting invitations to informal little dinners of intimates and always contributed largely to the gaiety and interest of the meeting, whether as host or guest. Frequent in his visits to congresses in other countries he was well known, and in his quiet way he made himself extremely popular among his foreign brethren. Indeed, the present writer has been struck with the frequency with which in his sojourns abroad he has received cordial inquiries about "Bahbair." In his domestic life a more than usually sympathetic companionship was his lot. His own uncertain health demanded and received the most cheerful care at the hands of his devoted wife, while she in her turn was the subject of his technical ministrations. These mutual reciprocities seemed to bind them all the more tenderly to each other, and as their union was not blessed with children each seemed to find in the other the scope for that affection and solicitude which many find in their offspring. Under these circumstances Baber's many friends will feel unusual sympathy with his widow in her bereavement, and I am sure they will endorse every one of these few words of appreciation which I have felt impelled to utter regarding him.—I am, Sir, yours faithfully,

London, W., May 28th, 1910. DUNDAS GRANT.

NURSING HOMES.

To the Editor of THE LANCET.

SIR,—May I claim the courtesy of your columns to defend a class of institutions which at the present moment is being subjected to unjustifiable assault.

In their search for sensational copy certain papers have recently engaged in attacks on "nursing homes" and furnished their credulous public with highly spiced and lurid details of vicious and illegal practices committed within the walls of these so-called nursing homes. Of course, it is impossible to deny that nefarious practices are committed at certain of these establishments, and that their proprietors continue to hide their guilt from the eyes of the police by labelling their establishments "Nursing Homes," "Rest Houses," and so forth. All this is common knowledge, and, although the scandal exists and may even have assumed the proportion which has been alleged, the police authorities may be trusted to do their duty and exercise due vigilance in the interests of public morality. If it should be necessary to quicken their watchfulness, perhaps the present campaign may be justified, but as one intimately associated with the conduct of a nursing home I wish to protest as vigorously as I can against the great harm that is being done by this indiscriminate denunciation of nursing homes.

To many people, especially those of restricted means, a nursing home supplies a real want and is oftentimes a veritable godsend, as the only alternative is the general ward of a public hospital, with its necessarily rigid discipline and lack of privacy. That in some nursing homes, not justly entitled to that appellation, abuses exist is no excuse at all for wild and whirling attacks on institutions which fulfil an excellent purpose and are the means of alleviating a great amount of suffering without the excessive expenditure and inconvenience involved in home nursing.

For such abuses as do exist the remedy is a very simple one, and has been agitated for by all the proprietors of legitimately conducted nursing homes for many years past. That remedy is, State registration. Were this compulsory, such evils as are now being dragged before the public eye could not exist; establishments which are rightly conducted have even now no need to shun the light of day, but with universal registration there would be no possibility of the title "nursing home" ever being degraded in such a way as at the present time. Nor would there be the necessity for that lurid journalism which massacres the innocent as well as the guilty and frightens the timid and ignorant public. Thanking you for your courtesy in inserting this letter,

I am, Sir, yours faithfully,

May 25th, 1910. X.

THE SEASIDE CAMPS FOR LONDON WORKING BOYS.

To the Editor of THE LANCET.

SIR,—We again ask your kind permission to appeal to your readers for the funds necessary for the continuance and extension of these camps, which are now entering upon their twenty-second year. Of late they have been supported to an extent which has enabled us to provide each season for about 3000 London working boys a week's holiday by the sea. We earnestly plead with all friends of such lads, in whose hard-worked life there is little enough of wholesome change, not only to continue this support, but also to mark the completion of our coming of age year by an increased liberality to warrant our adding largely to the numbers our camp may benefit in future. For this purpose we now venture to ask for additional subscriptions or donations to the amount of £1000.

Many urgent claims nowadays appeal to the public, and year by year increasing efforts are rightly made to obtain funds for the camping out of Brigade lads and Boy Scouts, &c. We submit, however, that our work has a special claim of its own, in that it deals, in addition, with a vast number of working boys who are untouched by other organisations—boys of good character and scanty wages, but who belong to no Brigade or Scout corps and who are, in many instances, out of touch with any club or institute.

It is a condition of each applicant's admission to our camps that he shall contribute towards his railway fare and keep, but we need scarcely say that the larger part of the expense has to be provided otherwise.

Contributions will be gratefully acknowledged by the Secretary, Mr. F. Abel Bloxam, at 23, Northumberland-avenue, W.C., or may be sent direct to our bankers, Messrs. Cocks, Biddulph, and Co., 43, Charing Cross, S.W.

We are, Sir, yours faithfully,

ARTHUR J. INGRAM,
Chairman of Committee; Prebendary of St. Paul's.
EVERARD A. FORD,
Treasurer.
WALTER G. KLEIN,
Member of Committee.

May, 1910.

NURSING IN ITALY.

(FROM A CORRESPONDENT.)

MANY of the great hospitals of Italy are charitable foundations which have existed since the Middle Ages. Numbers of them are of interest historically and architecturally, and the traces of the past which are visible to-day are not confined to architecture alone. Signs of the care of the sick, which the Clerical Orders practised of old, are still to be seen in these hospitals, but in Italy to-day, as in Spain and Portugal, nursing is in a deplorably backward condition. The old-established religious system, under which the nuns of the various sacred orders worked, still prevails to a very large extent, and although their nursing is carried out with great devotion the standard of knowledge and skill is far from being up to what we in this country consider the minimum of a nurse's requirements. In 1890 Signor Crispi, the then Prime Minister, introduced the *Opere Pie* Act, reorganising the charities of Italy, its object being to transfer to the local authorities the charge of the public charities which had up to that time been managed by the clergy without any responsibility to the civil government. The Act was passed, and the various beneficent institutions were placed under committees elected by the

district councils and responsible to the provincial administrative authorities. But to pass an Act in Italy is a different thing from getting it enforced, and many of the hospitals, while their financial affairs and medical management are supervised by the State, leave their nursing service in the hands of the Church, which employs nuns, who are assisted by lay nurses, male and female. The nuns, for reasons which have never been made very clear, are always insufficiently trained. Their work and duties are not clearly defined from those of the lay sisters who are under them. They are under the orders of the Church, and obey the Church primarily, while also following the instructions of the medical officers of the hospital.

The condition of affairs in the hospital of an obscure seaport in Liguria (known to me) may be taken as typical of what still exists in many of the smaller provincial hospitals. The nurses in the wards of this hospital are of two classes: there is the *suora*, or nun, and the *infermiere*, or wardmaid. The nuns, all taken from the same Order, are devoted attendants on the sick, and minister also to the spiritual needs of the patients. They superintend and direct the service of the kitchen and pantries, see to the supply of the food, supervise the cleanliness of the hospital, and direct the work of the servants generally. The qualifications for becoming a lay nurse, or what is practically a wardmaid, are as follows: to be healthy, to be a native of Italy, and to have a knowledge of reading, writing, and of the first four rules of arithmetic. Candidates must be between the ages of 18 and 25, and female applicants must be single. These qualifications are excellent as far as they go; but some additional training would seem to your readers to be very necessary, yet in many of the hospitals they get no such additional training. Their only knowledge is that gained in the course of their daily work. Many of the larger hospitals have courses for the instruction of their nurses, but I am speaking now of a small provincial hospital. These lay nurses are taken from a class which is in many respects inferior to that from which the ward maids in our hospitals are recruited. They are rough, ill-educated peasants, wholly untrained. In many of the hospitals their costumes are of coarse serge material, quite unsuited for wearing while working in the operating theatre. Their pay averages 2 lire a day for a male nurse, and less for a female. Undoubtedly through their experience in the wards and in the operating theatre they learn something of the duties of a nurse, but they are under the supervision of nuns who usually have not any medical knowledge, supplying, as best they may, their lack of it by their assiduity, so that what training the nurses obtain is due mainly to their own wit and attention—qualities which they may possess only in the slightest degree.

This system of having two distinct classes of attendants in the wards does not further the efficient nursing of the patients. The Anti-Clerical party in Italy, which is day by day becoming more powerful, in continuance of its policy of curtailing the power of the Vatican, will try to oust the Church of Rome from her foothold in the hospitals. And if the nuns who work in the hospitals continue untrained the Anti-Clerical party will have the support of the medical profession. It is not that the sisters of the various religious orders are wanting in devotion, in physical strength, in sound health, in sense of duty, or in intelligence. They have all these. But these qualities are only the foundation upon which a good medical training should be laid. Nuns who are not efficiently trained should not be in the hospitals, exercising the authority which they do. They hinder the proper nursing of the patients by the few lay nurses who have the requisite knowledge, and they can impart no medical knowledge to the lay nurses who are without it. Nursing is not looked upon as a profession by the nuns. It is often merely an incident in their lives of devotion. Nor does the Church herself regard it as a profession for them, apart from their religious work. The nuns are in the hospitals primarily to care for the souls of the patients, and the actual nursing is to them a purely secondary consideration. Admiration of the whole-hearted service which they give is tempered by a regret that they should interfere with the actual nursing of the patients at all.

To-day in Italy the old order of things is disappearing. Changes are taking place on all sides, and these changes are very closely associated with the workings of the Anti-Clerical party. The Church of Rome will assuredly lose a great opportunity if she does not give a medical training to the Sisters of Charity whom she sends to work in the great hospitals of Italy. The religious work which is done by these Sisters is noble, but it is performed in such a way as to interfere with the proper treatment of the patients by the lay nurses. Let the Church of Rome train her nuns as efficient nurses and she will disarm all possible criticism from either the Anti-Clerical party or from the medical profession itself. At present the nuns are educated but have little medical knowledge, and the lay sisters, who have some practical knowledge of nursing, are ill-educated.

HEALTH PROBLEMS IN THE POTTERIES AND THE FEDERATION OF THE SIX TOWNS.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

Concluded from p. 1502.)

Domestic Drainage and Vital Statistics.

AT Stoke we have insanitary conditions similar to those which I recorded last week for Longton, though less accentuated, for the inhabitants of Stoke are rather more prosperous than their neighbours. The populations are almost the same. In 1909 there were 38,287 inhabitants at Longton and 37,040 at Stoke; but while there remained 1809 cesspool closets at Longton there were only 1565 at Stoke. In 1908 there were 1668, and in 1907 there were 1719 cesspool closets in the borough. It will be seen, therefore, that the number of cesspools is gradually decreasing. There are now in Stoke 4757 water-closets with the regulation flush, 805 hand-flushed closets, and 675 slop water-closets. At Longton there are only 2867 proper closets. The domestic drainage being thus better at Stoke than at Longton, how do the vital statistics compare? The birth-rate at Stoke equals an average of 30·8 per 1000 for the ten years from 1899 to 1908, but it fell to 27·15 in 1909. During the same ten years the average at Longton was 36·4 per 1000, which fell to 33·7 in 1909. With a higher birth-rate we may expect a poorer population and a higher infantile mortality. This, however, is hardly a sufficient cause to account for the following excessive mortality among infants. In Stoke the largest infantile mortality recorded was 224 per 1000 births in 1899, which is bad enough, but at Longton it was 255 in 1900. The average for the ten years 1899 to 1908 was 160 at Stoke and 210 at Longton. For 1909 the figures were 128 at Stoke and 156 at Longton, both boroughs showing the improvement which is such a feature in the later English statistical records. The general death-rate has always been lower at Stoke than at Longton, amounting to 13·9 and 19·6 respectively in 1909. The fact that there is less poverty at Stoke must contribute to lowering the death-rate, but the better domestic drainage is also an important factor. Besides here, as at Longton, there is always some enteric fever. In 1907 there were 31 cases of enteric fever notified, 40 in 1908, and 32 in 1909. Year after year the medical officer of health of Stoke, in his annual reports, declares that the quality of the water-supply is good, but that the quantity is insufficient, and that a large number of closets are not flushed.

Hanley is much the largest of the six towns. Last year its population was estimated at 68,831. The birth-rate is high, for 34·3 per 1000 was the average for the 10 years from 1899 to 1908, and 31·3 for the year 1909. This birth-rate, though lower than that of Longton, is higher than that of Stoke. The average infantile death-rate per 1000 born was during the 10 years 185, and in 1909 it fell to 149, the figures again falling midway between those of Stoke and Longton. But the details show that previous to last year the birth-rate, though fluctuating, did not seem to decrease, yet the mortality, especially the infantile mortality, was decreasing. During all that time the authorities were so active in dealing with domestic drainage that they now boast of having practically abolished the cesspools. There only remain 70 of these abominations in the entire borough of Hanley. On the other hand, there are no less than 6760 water-closets with proper flushing cisterns. Then we have 4000 cottage basin hand-flushed closets, which are usually properly constructed, but depend for their sanitary qualities

on the trouble taken to keep them in decent order. There are 300 closets that are flushed by the slop or waste water of the house, which accumulates in a tipper which discharges when it contains enough water to constitute a flush; and 1150 other closets into which the slop water flows without a tipper. Finally, there are 1350 pan closets. This is a metallic pan placed under the seat and periodically removed. These contrivances are unsatisfactory in certain ways—all of them—but they are not as dangerous to the community as cesspools.

These various systems of closets exist throughout the six towns. At Burslem the sanitary authorities, like those of Longton, give figures that set forth the relations between enteric fever and domestic drainage. Thus, in 1908 there were 20 cases in 20 different houses, but only two of these houses had proper water-closets. In 1909 there were cases of enteric fever in 32 different houses, and only three of these houses had sanitary water-closets. Four of the houses had cesspools. At Burslem, for a population of 44,310, there were, according to the last report, some three years old, 1600 water-closets, 2600 hand-flushed closets, 2800 waste and slop water-closets, and 1435 cesspools. By now the number of cesspools has probably been reduced to 1200. Eight years ago in one single street in the district of Cobridge there were 14 cases of enteric fever. The sanitary authorities ripped up all the drains, relaid them, repaved or concreted the cellars, and there has not been a single case in the district since the repairs were effected. The general statistics of Burslem are in keeping with the unsatisfactory condition of the domestic drainage. The average infant mortality for the ten years (1899–1908) was 190, and for the year 1909 it was 179.

How the Present Condition of Domestic Drainage was Reached.

As the necessity of water-closets and the inferiority of all the other systems are now generally recognised, surprise may be felt that so many old-fashioned methods are still in use when there are sewers all over the district whose chief defect would be remedied by use. The householders, however, cannot be compelled to connect. If every house sent a two-gallon flush into the sewers each time a closet was used, there would not be so many complaints of bad odours coming from the man-holes, nor would men be seen going about with rods to clear out hand-flushed drains. It would not be necessary in dry weather to pour water into the sewers and to scatter disinfectants about, but no sewers can be expected to work properly unless there is an ample flush in the closets. Though everyone is now agreed as to what should be done, this was not the case as recently as 40 years ago when the authorities were advising the construction of cesspools, and the larger the cesspool the better. In the course of years these same authorities began to find that smaller cesspools were preferable. Now they will not allow a new house to have any cesspool at all, whether big or small, and, further, they seize every pretext for abolishing such cesspools as exist. But when the authorities first condemned cesspools they had not yet realised the value of enforcing the adoption of water-closets. They were satisfied to recommend and to sanction closets that had below the pan a broad pipe, perhaps 8 inches in diameter and 3 to 4 feet in length. At the lower part of this pipe there is a syphon trap, and into it drains the slop or waste water from the house or cottage. The pan and pipe remain in a foul condition, there is nothing to clean them, but the soil and slops of the house are drained away to the sewer without adequate flush. The tip, or revolving receptacle which retains the slop-water till a certain quantity has accumulated, is better; the weight of the water which causes it to overbalance furnishes more effective flush. But by the time the slop-water has travelled from the house to the closet, which is generally at the farthest extremity of the backyard, it has reached so low a level that the closet-pan and a large part of the pipe is above this level and therefore receive no flush at all. Also and at best a flush of only dirty water is not the ideal. Kitchen and vegetable water is often highly offensive.

After this, to say the least of it, nasty system had been recommended, the authorities evolved yet another stage. They now recommended what is a water-closet in every respect, except that the all-important question of water is improperly dealt with—that is to say, each person is supposed to flush the pan after use by means of a hand-conveyed jug. But this system was bound to create one of two objections. Either people would neglect to take t water, in which case the closets would become foul a insanitary, or else they would take sufficient water to ke them clean, in which case they would be consuming wat that had not been paid for at any rate at that rate of co sumption. Needless to say, the water company at once entere the loudest protests against this form of drainage. The lan lords who had adopted one by one all the various metho recognised by the authorities and who were now brought int conflict with the water company showed signs of fatigu They were attacked for having too faithfully followed th advice of some previous council, and the actual authoritie began to feel they could hardly upset all that had bee done without sharing the expense.

Advantages of Amalgamation in regard to Drainage and othe Matters.

There is throughout the Potteries an unlimited supply o good water. It never fails even in the driest seasons, bu it belongs to a private company which charged even th poorest cottages 6*s.* 6*d.* a year if they had a water-closet. The small cottage owners needed some assistance t convert their privies into water-closets and to pay a higher water rate. This was given at Hanley. The water company reduced its charge to 3*s.* 6*d.* per cottage, it being agreed that the building of no new house would be sanctioned unless it had a proper water-closet. The same rule obtains at Burslem, and it may be safely inferred that the errors will not be repeated in new houses. But what is needed at once is a scheme for connecting all the houses, the old as well as the new, with the existing sewers. This is obviously the first task the new united borough should undertake. All the nasty contrivances described above must be swept away and closets with a minimum flush of two gallons provided instead. Then there will be a sufficient quantity of clean water within the sewers during dry weather to prevent any nuisance occurring if the sewers have been constructed on self-cleansing principles.

Doubtless some improvements would be effected in the working of the sewers by amalgamating the six different systems. Burslem and Hanley have expensive sewage purification works, and the question arises whether these might not be now used to treat the sewage of a more extensive area. Here again we have a good illustration of the advantage of federation. It would, of course, be absurd to perpetuate six different drainage schemes and six different sewage disposal works for what is practically one single town.

In regard also to the question of meat-supply the federation of the towns should take efficient action. This is a very favourable moment, for the population expects something new—what would be the use of federating if things are to remain just as they were before? Therefore the new borough council need not fear creating alarm by taking a bold initiative. This, on the contrary, is just what is expected from them. Consequently they might very well propose the abolition of all the private slaughter-houses and the establishment of a model municipal abattoir. The principal objection to necessary reforms is the cost and the fear of an increase in the rates. But this very necessary measure would, on the contrary, mean an increase of the municipal revenue, if it is done on a large scale, including the utilisation of all the by-products. The experience of 900 municipal abattoirs in Germany confirms this contention, and the experience of each of the six medical officers of the six towns sets forth the necessity of such a measure. At Longton there was much bad meat put on the market, and it was only after many prosecutions had been undertaken and very heavy fines inflicted that the butchers began to send for the inspector when they thought their meat was not wholesome. At Stoke complaints are made in regard to the nuisance caused by tripe boiling. Then it appears that dogs and horses are kept in the lairs attached to private slaughter-houses, and that "under the present conditions it is impossible to effectively inspect meat sold in the borough."[1] At Hanley an attempt has been made to provide a public slaughter-house, but on so small and limited a scale that there still remain 17 private slaughter-houses. There are also 17 private slaughter-houses at Burslem which were inspected 404 times last year. One, or at most two public abattoirs for the whole of the six

[1] The Annual Report for 1907 of the Medical Officer of Health of Stoke.

towns would amply suffice. The great waste of time and labour in petty and ineffective visiting would be economised. Given a big enough abattoir there would always be a veterinary surgeon on the premises, the inspection would be done by highly qualified persons and there would be no incursion into private premises.

Such are some of the advantages that, with intelligence and enterprise, may ensue upon the federation of the six towns. Of course, we are as yet only on the threshold and there is much to organise in regard to the details of administration. At the same time it rarely happens that a large community has so excellent an opportunity of initiating new policies and taking a bold step forward.

PLAGUE IN THE NEAR EAST.

(BY THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.)

Plague in Jeddah.

THE plague epidemic in Jeddah, or rather its seasonal revival, seems to have come to an end. The following figures are in continuation of those published in my last letter (THE LANCET, May 7th, 1910, p. 1300):—

Week ending April			10th,	12	cases,	13	deaths.
,,	,,	,,	17th,	11	,,	9	,,
,,	,,	,,	24th,	5	,,	7	,,
,,	,,	May	1st,	6	,,	5	,,
,,	,,	,,	8th,	0	,,	0	,,

The total number of cases since the beginning of the outbreak on Jan. 5th has been 99, and of deaths 97. It is almost certain that these figures are below the truth, particularly that for the number of deaths.

Among the victims of the disease has unfortunately to be counted Dr. Zonchello, the acting sanitary officer of Jeddah, whose illness was mentioned in the letter above referred to. He died on April 17th. He had been largely employed in making necropsies and bacteriological examinations of rats caught in the town, many of which were found to be plague infected, and it is thought that it was in the course of these investigations that he contracted the infection. His death causes a real loss to the administration, as he was one of the most active and zealous of the younger medical officers in its service.[1]

Plague in the Yemen.

News was recently received of the appearance of a suspicious disease at Loheia, a small port on the Yemen coast of the Red Sea. The medical officer of Hodeidah was sent to inquire into its nature, and on April 21st he declared that the disease was plague, and that three deaths had occurred; two days later it was reported that 17 cases, with 7 deaths, had been registered, and it was added that the outbreak had been preceded by an epizootic among rats. The diagnosis of plague was confirmed bacteriologically. Another telegram, dated April 30th, stated that there had been in all 31 cases, with 24 deaths. Finally a telegram, dated May 5th, reports 8 additional cases, with 5 deaths. The disease is also said to exist at three other places in the neighbourhood, the names of which appear in the telegrams as Badjet Moniera, Yss, and Hadjour.

Plague at Bushire.

The appearance of the disease in this port of the Persian Gulf was mentioned in my last letter. The following news has been received since. On April 19th a fatal case occurred; on the 30th, 4 cases, with 2 deaths, were reported (probably as occurring in the interval); and in the week ending May 7th there were 12 cases, with 8 deaths. Nothing is as yet known as to the origin of the infection here, nor in the case of the epidemic in the Yemen, mentioned above.

Plague at Basra.

On April 27th news was received of the occurrence of two cases of plague in the town of Basra (not far from the head of the Persian Gulf). The first case was that of an Indian girl, who had already died from the disease; in the room where she had died her mother was found ill with the disease. Both seem to have been long resident in the town. Of two boatmen who were among the isolated "contacts," having secretly buried the body of the first case above referred to, both showed symptoms of the disease on April 30th, and one died. Another case among the "contacts" was reported on May 4th. Two dead rats found in the house of the first cases were examined bacteriologically and found to be plague infected.

The Death from Plague in Mecca.

Details have now been received of the death from plague in Mecca, which was mentioned in my last letter. The body was only seen after death, which occurred on March 12th. The patient had been long resident in Mecca, and was not known to have had any relations directly with Jeddah. He was a Circassian.

Constantinople, May 14th.

[1] See THE LANCET, May 21st, 1910, p. 1447.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Montrose Health Report.

THE annual report of Dr. Middleton Connon, medical officer of health of the burgh of Montrose, remarks that the birth-rate for the year was the highest for 11 years, and the death-rate the lowest for seven. The infantile mortality rate, though decreasing, was still high, and many of the deaths might have been avoided. Cases of infectious disease were 45, as against 55 the previous year, and a further reduction was probable after the improved water scheme was effected. Dr. Connon strongly advocates compulsory notification of consumption, and adoption of the Notification of Births Act.

Obituary.

The death took place very suddenly at Tain on Saturday, May 21st, of Dr. J. J. Y. Dalgarno, of Aberdeen. Dr. Dalgarno had arrived the previous evening in order to assist as anæsthetist at an operation. When he was called on the following morning it was discovered that he was dead. Death was due to heart failure. Dr. Dalgarno graduated M.A. at the University of Aberdeen in 1883, and took his M.B., C.M. degrees in 1887. For the past 12 years he had been on the staff of the Aberdeen Royal Infirmary, and during practically the whole of this time he had officiated as senior anæsthetist. For ten years he acted as one of the medical officers to the Aberdeen Dispensary, while he held also the post of medical consultant to the Aberdeen parish council. The deceased gentleman is survived by Mrs. Dalgarno and three daughters. The funeral took place on May 24th at Allenvale cemetery, and was largely attended by members of the medical profession and business gentlemen in the city.

The death of Dr. David Cowie of Glasgow occurred on May 28th. Dr. Cowie was born in Nova Scotia; he came to Scotland at an early age and studied at the University of Glasgow. For many years he had an extensive practice in that city. He acted as resident house surgeon to the Glasgow Royal Infirmary and afterwards held the post of surgeon to the Duke-street Prison. He was the senior district surgeon to the Glasgow parish council, and held the rank of surgeon lieutenant-colonel in the 5th V.B. Highland Light Infantry Brigade.

I have to record also the death of Dr. James Finlay of Lindisfarne, Helensburgh, on Thursday, May 26th, in his seventy-fifth year. Dr. Finlay was trained at the University of Glasgow. He practised at first at Stranraer, and in the early "sixties" moved to Helensburgh, where he worked for over 40 years.

May 31st.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The National University.

LAST week for the first time since its inception Congregations of the National University of Ireland were held for the purpose of conferring degrees. On May 24th at Dublin and on the 25th at Cork the Senate met, all the degrees conferred being in the Faculty of Medicine. The position of the University as regards local habitation is curious, in that while officially its seat is Dublin, not merely are examinations to be

conducted locally in the constituent colleges, but degrees are to be conferred locally. The President of University College, Cork (Professor B. C. A. Windle), took the opportunity afforded him as Pro-Vice-Chancellor in the Congregation held at Cork to put forward his views as to the autonomy to be ultimately gained by the College of which he is head. Whereas at present the College is autonomous inside the University, he looks to it to develop into an independent university just as Belfast University has become an independent university, though founded as a constituent college. The present position, which keeps the Cork College more or less subordinate to Dublin, he regards as "undignified and educationally indefensible." He appeals to the people of Munster to press forward their claims for a university of their own, saying: 1. In the first place, Munster must send its sons and daughters to be educated there. If there were no students, or only a small band, it was obvious that there could be no demand for a university—at least, no real demand. In this connexion he might say that last year the number of students was higher than it had been at any time for 20 years, and that this year there were about 100 more than there were last year. He looked forward with confidence to a further increase next session, but, meantime, he was not discouraged by the start which they had made. 2. Pecuniary aid must be given. The inhabitants had not as yet been appealed to. The appeal would be made in due course, and he felt confident that it would be adequately responded to. If it were not, he feared that it would be another generation which would see the University of Cork make its bow to the public. 3. Lastly, they must feel a pride in the College and they must say so. With reference to these local Congregations, and in particular to Professor Windle's ambitions for Cork, Dr. J. P. Pye, professor of anatomy at Galway, writes to the daily papers that the proceedings in the University Colleges of Dublin and Cork, where degrees were granted and conferred locally this week, must be unintelligible to those who believe in the existence of a National University. If the National University is to be merely a stage to three provincial universities better have the latter at once. The history of the Queen's and Royal Universities might at least teach that a reasonable amount of finality is desirable in University legislation. In the divergent views of Professor Windle and Professor Pye lie the two roads at present before Irish University education. As Professor Windle urges, Cork is anxious to break away from the National University and to stand alone. Galway is too weak for independent life, and clings to the composite idea. Dublin is probably indifferent.

Children as Beggars.

Some correspondence has appeared in the daily press lately on the subject of the street beggars who are a familiar feature of Dublin life. Dublin has always been noted for its crowds of beggars, but all residents have observed the great increase in their numbers in the past seven or eight years. They seem to be quite free from police interference, and it is believed that in recent years the police are not officially encouraged to arrest or prosecute street beggars. A large proportion of the beggars are young children, girls and boys, who remain in the streets almost till midnight. Many of the girl children are growing near puberty, and it is not too much to state that they are serving an apprenticeship for prostitution. Meanwhile, the condition gets worse and worse, and the police remain inert.

Post-graduate Classes in Dublin.

The first week of June sees post-graduate work in Dublin in its fullest activity. Two sets of classes are being carried on, one organised by Trinity College, and one by the Royal College of Surgeons. The aim of the two courses is different. Trinity College selects certain teachers to give instruction in certain subjects on which they can speak with authority. The Royal College of Surgeons, on the other hand, attempts to put all the clinical material of the city at the disposal of the class, and with this intent invites all the clinical hospitals to coöperate, each hospital to arrange with its own staff for a certain number of hours' instruction. It is a little unfortunate that the two courses should be arranged to run concurrently, but it is difficult to fit in the work otherwise without disarranging the ordinary work of the session.

Hospital for Diseases of the Nervous System, Belfast.

At the annual meeting of the supporters of this institution held on May 27th, it was reported that the total income for the year was £633 18*s.* and the expenditure for the same period £683 1*s.* 11*d.* There were during the year 69 intern and 531 extern patients treated in the hospital. Dr. David Gray has been appointed honorary assistant physician, Dr. John MacCormac, the founder of the hospital, still remaining physician.

Epidemic of Measles in Belfast.

At a meeting of the Belfast public health committee held on May 26th a report was presented by the medical officer of health showing an alarming increase in the mortality from measles, the number of deaths for the previous week having been 44, as compared with 23, 19, and 20 in the previous three weeks, which figures were themselves abnormally high. This death-rate is attributed to carelessness on the part of parents in not getting medical advice until too late. The disease being not notifiable renders the public health department almost powerless. The medical officer of health submitted a statement as to the precautions that should be taken which was approved of by the public health committee, which asked the coöperation of the press in making the memorandum public. It accordingly appears in the daily papers of May 27th.

Down District Asylum.

The monthly meeting of the committee of management of the Down District Asylum was held on May 28th. In his annual report, which was presented at the meeting, Mr. M. J. Nolan stated that of the 90 persons discharged 81 were "recovered," 7 were "relieved," and 2 were discharged "not improved." These two latter discharges were made at the request of relatives who were in a position to take adequate care of the patients. The recovery rate was 55·1 per cent., a considerable improvement upon that of last year, when it was 49. Mr. Nolan stated that the average percentage of recoveries on the admissions for all the Irish asylums was 36·9 per cent. for the last recorded year.

May 31st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Death of Dr. Léon Petit.

Dr. Léon Petit, general secretary of the Ormesson Hospital for Tuberculous Children, has died by his own hand at his residence, having hanged himself with a picture-cord. On account of the circumstances which led up to it this tragic event has caused a great sensation in Paris, where he was very well known. Born in 1854, possessed of great mental activity, and an excellent public speaker, Dr. Petit devoted himself almost entirely to philanthropic undertakings and the encouragement of athletic sports. He was vice-president of the French Touring Club, in the development of which he did a great deal by speaking at meetings and making journeys, and he had contributed in no small degree to the revival of athletics among young people in France. In 1893, with the assistance of a nun who belonged to a country district and was known as Sister Candide, he founded the asylum for tuberculous children and the special hospital at Ormesson, an undertaking which had a very favourable reception; in a short time it was well supplied with funds by the charitable public, and each year the Government allowed a lottery which brought in 1,200,000 francs to be organised in its behalf. The committee of management, presided over by old Dr. Herard, included persons well known in the learned world and in high society, whose names were everywhere respected. Sister Candide also became very popular; she was regarded as a pattern of devotion to duty, and the Government had even nominated her Chevalier of the Legion of Honour. Astonishment was therefore felt when it became known that she was charged with committing frauds on Paris jewellers by obtaining from them expensive jewellery, which she immediately resold without having paid for it. The evidence showed that she had in fact made many dupes among the jewellers, and that she had been taken advantage of by them just as happens to young men belonging to good families and anxious to get possession of ready money without counting the cost. It was then found that her need of

money was brought about by the necessity of keeping up new charitable undertakings which she had founded after the one at Ormesson—in particular of a sanatorium for children at Saint Salvadour in the department of the Var, where at the same time she had a financial interest in the sale of a mineral water containing lithium. The charitable institution at Saint Salvadour had for its patron M. Loubet, at that time President of the Republic. Unfortunately the nun had little knowledge of business matters and by her experience at Ormesson was accustomed to see money come easily to hand. Her outlay on the erection of the buildings at Saint Salvadour was altogether unreasonable, the result being that her affairs became hopelessly involved, for the subscriptions of the charitable public declined and the lotteries, which had been too numerous, at last brought in nothing at all. She then commenced borrowing money on jewellery which she had obtained on credit, and some of it was said to have been pawned in London. Dr. Petit having been associated with Sister Candide in the work of the children's hospital at Ormesson, now found himself placed in a very awkward position by her subsequent misconduct. He had himself incurred great liabilities by founding at Saint Salvadour an immense sanatorium for the reception of paying patients, but it had so little success that he was soon forced to sell it to a company which transformed it into a palatial hotel. At this period he separated himself completely from Sister Candide, but when she was prosecuted he endeavoured to shield her, apparently out of friendship, appealing to wealthy philanthropists for money to satisfy her creditors. Some newspapers now insinuated that he was implicated in the frauds committed by her, and that the money which he was attempting to raise would serve to cover up his own shortcomings. He did not succeed in procuring sufficient money, for the inquiry brought to light every day some fresh trickery on the part of the nun, and the liabilities were brought up to 8,000,000 francs by the machinations of moneylenders. He then took his own life, leaving a letter in which he not only asserted his innocence, but accused Sister Candide of having spread ruin and death around her, and since his decease his family has been able to prove that he had not for many years been working in association with her.

Medical Men and the "Bourse du Travail."

The Bourse du Travail in Paris, which is the local headquarters of various associations (*syndicats*) and in particular of workmen's trade unions, has become, as is well known, an active centre of revolutionary agitation. The majority of these associations are affiliated to an organisation called the General Confederation of Labour, which openly preaches social revolution, encourages strikes, and makes arrangements for revolutionary manifestations of every description, including even disturbances in the streets. During the last few years certain members of the Association of Medical Men of the Seine have several times proposed at the general meetings that their association should seek admission to the Bourse du Travail. These proposals were rejected, not only by the medical association, which considered that the Bourse du Travail was no place for medical men, but also by the Bourse du Travail itself, which claimed that it was reserved exclusively for combinations of workmen in conflict with combinations of employers, and that an association of medical men was ineligible for admission, as its members held the position of employers. Those of the medical association who favoured the new departure hoped thereby to strengthen their association, for the Government had shown that it always yielded to the demands of the Bourse du Travail without ever doing anything requested by the medical association. Last week some medical men, with Dr. Divernesse of Saint Mandé at their head, formed themselves into an association and were affiliated to the Bourse du Travail, a step regarded with disfavour in medical circles and also among the general public, especially since the means by which the new association overcame the previous scruples of the Bourse du Travail have become known. It appears, in fact, that the new association has been formed for the purpose of issuing medical certificates to workmen who have met with accidents in the course of their employment and who will use these certificates in any dispute with the insurance companies which pay compensation to workmen. The question is in reality an episode in the campaign which certain medical men long ago opened against the medical officers of the insurance companies. It is in the interest of these companies that their medical officers should not overstate the severity of an accident and that the period of inability to work should be made as short as possible. Their medical opponents, on the other hand, say that the workman should have his injuries reported on by a practitioner of his own selection—the result of which system would, it is asserted, be that the practitioner, in order to conciliate the patient, would do all that was possible in his estimate of the severity of the injuries, with a view to the payment of liberal compensation. This campaign against the medical officers of the insurance companies has already caused heated debates in the Association of the Medical Men of the Seine, and the new association, which proposes to compete with its professional brethren, to seek popularity with the working classes, and to issue certificates avowedly unfavourable to the assurance companies, is not received with much cordiality.

(FROM OUR OWN CORRESPONDENT.)

The Fight against Malaria.

THE event of the week has been the full-dress debate, "Sulla Questione Malarica," before the Royal Medical Academy of Rome. Lasting for two entire sittings, its chief interlocutors bore the authoritative names of V. Ascoli, G. Baccelli (the President), A. Bignami, B. Campana, A. Celli, L. Ferrero di Cavallerleone, G. Galli, B. Gosio, and J. Gualdi. At the close the following order of the day was accepted:—

The Royal Medical Academy of Rome, after ample discussion, having carefully examined the opinions recently maintained as to the course to be pursued in the "campaign against malaria," and also the facts on which these opinions are based, holding that the adoption of prophylactic measures, associated with the therapeutic treatment of malarious patients in localities heavily visited by the disease, is a condition essential to satisfactory results in undertaking the permanent reclamation of the soil and, generally speaking, in agricultural labour as a whole, so as to minimise the risks to the labourer's health; recognising the incontestably beneficial effects obtained in malarious localities by the prophylactic use of quinine associated with the early and systematic treatment with the same, and recognising, however, the innocuousness of the prophylactic exhibition of the drug, recommends to physicians and sanitary authorities (1) to diffuse and intensify the prophylactic use of quinine in all localities gravely affected by malaria; and (2) to render more systematic and effective the medical attendance and the medical treatment in such localities.

Dissociating himself from this finding of his colleagues Dr. Baccelli writes: "I did not vote because, elected at Milan by the unanimous suffrages of 700 physicians to act as president of the 'Lega Nazionale contro la Malaria' I knew the dissent profoundly entertained by many of them from the two propositions virtually and explicitly contained in the order of the day, to wit: (1) that the prophylactic use of quinine in small doses, exhibited daily, preserves the healthy subject from infection; and (2) that quinine so exhibited is innocuous to the human organism. Neither the one nor the other of these affirmations is fully borne out by the facts. Against the first I got one of my clinical assistants to read to the Academy the report of a typical case occurring in my own clinique just as I had begun my course of lectures on malaria. A young agricultural labourer, in spite of quinine faithfully exhibited prophylactically, incurred an attack of the fever, and thereafter a relapse. As to the second affirmation (the innocuousness of quinine prophylactically ingested), to say nothing of the ample experience of general clinicians, special clinicians of the authority of Professor Cirincioni in eye diseases and of Professor Ferreri in those of the ear have compiled a mass of evidence absolutely subversive of the affirmation in question. For these two reasons I begged the Academy to confine itself to the only proposition that was incontestable—to wit, that 'the State-law for the supply of quinine was a provident and sacrosanct measure,' and, by so confining itself, to avoid dogmatising on matters still *sub judice*. But I was not successful." To this communication, authoritative as it is, and supporting the views held by such an eminent pathologist as the late Professor Tommasi Crudeli, a rejoinder appears from the pen of Dr. Bignami admitting that the prophylaxis to be obtained from quinine was not invariably realised in cases in which it had been expected, but asserting that malaria numbers fewer victims among those who have undergone it than among

those who have not. As to the innocuousness of the repeated and systematic ingestion of quinine, taken, so to speak, as a "food," he meets assertion by assertion, denies that Professor Cirincioni found in practice that the visual apparatus had been injured by cinchonism or that Professor Ferreri had in his aural practice any injurious results to report from the same cause. Deprecating the hindrance likely to accrue to the State efforts against malaria by such excess of caution as that recommended by Baccelli, he invokes the experience of the hygienists of other nations, notably the English, the German, and the French, emphasising the conclusions of the "Congresso Antimalarico" held last year at Simla, where the prophylactic efficacy of quinine and its general innocuousness were unreservedly maintained. Dr. Baccelli's reply to his young colleague has yet to appear. Meanwhile, Dr. Grassi, agreeing with the order of the day, deplores the absence in the discussion and in the order of the day itself of all reference to the "mechanical protection" afforded by wire netting against the attacks of the anopheles. The effects of such protection in reducing the number of victims to malaria are not less noteworthy, he asserts, than those ascribed to the exhibition of quinine in prevention and cure. On the State railways, at the royal shooting-boxes of Castel Porziano and San Rossore, the netting has been used with the best results, and he winds up his earnest and impressive plea for "mechanical protection" with these words: "The protection in question is of the greatest value and, face to face with the signal benefits it produces—a healthy population instead of an ailing one for the greater part of the year—we may treat the sacrifices it imposes as a 'negligible quantity.' But, be it well understood, we ought never to dissociate the mechanical protection from the 'radical cure' of the disease." It is in this last sentence that the gist of the whole discussion lies. How is malaria generated? In other words, may not the locality which breeds and sustains the anopheles be itself a source of disease to the human subject, predisposing him (if nothing more) to the infection? Italian opinion seems slow to grasp the induction that the "carrier" of the poison can also be its "cause"—holding, in fact, that the true prophylaxis is to regenerate, to rehabilitate the soil from which originates the atmospheric taint without which the anopheles would cease to be. The "justissima tellus," to quote the pregnant words of the poet, *par excellence*, of nature-study, cannot be neglected or abased without exacting a retributive penalty. It is in this sense that the more scientific of Italian hygienists are at present working, and, while protecting or curing the labourer by medical means, tentative as well as recognised, they are striving to restore to the soil its normal conditions by every process known to agriculture in its highest development. Of the movement in this direction we are promised gratifying proof of progress in the organ of the "Lega Nazionale," the *Bollettino*, edited by Professor Gosio, Professor Gabbi, and their colleagues.

May 28th.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

Defective Sanitary Service among the Troops Fighting in Albania.

IN Albania the Turks are trying, with rather little success, to subdue the unruly, reactionary elements of mountaineers of that unhappy province. It appears that whereas the fighting attitude of the regular Ottoman troops makes an excellent impression and their equipment and training are admirable, the sanitary service has been altogether neglected. The transport of wounded, for instance, is exceedingly defective. There is only one ambulance train and the hospital accommodation is far from being efficient. Complete neglect is shown in attending the disabled and wounded, as well as the ailing, the medical service being altogether inadequate.

The Lunatic Asylum at Magnesia.

Under the heading of "A Social Drama" the Young Turkish newspaper *Tanin* publishes a startling article on the dreadful conditions prevailing at the lunatic asylum at Magnesia, a town about 40 miles distant from Smyrna. This public institution is said to be "not an asylum, but a grave." Almost every lunatic that enters it soon dies. On one day, for instance, March 15th of this year, as many as five persons died in it. On Dec. 21st, 1909, a poor woman was sent in without any previous medical examination. She died soon afterwards. In the report of the President of the Inquiry Commission, Sadik Bey, the asylum is spoken of as a "cemetery" where the ailing are buried alive. The most primitive rules of hygiene are habitually and continually neglected. Not only is there no psychiatrist in the institution, but no medical attendant whatever. Sadik Bey recommends the immediate closure of the asylum if the Government is unable to introduce strict and urgent reforms without delay. He concludes his report with the following striking words: "If the starving and badly clad human beings, who live in damp cells without light and without air, are not removed, and that as soon as possible, to a suitable hospital, I shall shut up the institution on my own responsibility and remove the patients from this 'living grave' on the ground of public justice and humanity." It seems that the lunatic asylum had several medical men, but the Government dismissed them in attempted efforts at economy. This is, of course, a deplorable way of procedure on the part of the Turkish authorities, who profess to aim at thorough reform for the benefit of the public weal. Places where venereal and other infectious diseases are raging have been left, on the same dubious economical grounds, without medical men, and in the capital itself physicians in the public sanitary service have been reduced to a miserable minimum. But the brave Turks have their own way of introducing the innovations of culture and civilisation.

The Street Dogs.

Constantinople, it has been decided, shall be freed from its innumerable street dogs that have for so long a time infested the city. The dogs are being caught at night time and transported in special vans to Top-Kapou, a district in Stamboul. Of their further destiny little is known as yet. The whole thing is done as quietly as possible in order not to excite the hostility of the Osmanlis, who cared for their dogs as if they were really useful and indispensable domestic animals. With the removal of the street dogs there will disappear from Constantinople one of its most bizarre historic features.

The Introduction of the Bull-ring.

A concession has been granted to an enterprising individual allowing him to introduce into the Turkish metropolis regular bull fights, and we may expect all the usual evils in connexion with these displays. A vigorous protest has been raised by a small section of the population, but without any result.

A Lottery for Sanitary Improvements.

The Grand Rabbi of Constantinople has asked the permission of the Turkish authorities to organise a public lottery in order to raise £7000 for the construction of new Jewish schools, for the repair of the existing ones, and for the thorough sanitary amelioration of all of them. The Grand Rabbi has also asked for a Government subvention in aid of the Jewish hospital, *Or-Ahaim*, at Balat, on the right shores of the Golden Horn. I have visited this hospital on several occasions and found it doing good work. Its equipment is, however, very deficient, and the medical service leaves much room for improvement. It seems that the Turks have already been allotting some little grant to this useful institution, seeing that it opens its doors to patients of all nationalities. Yet it is not likely that the Ottoman authorities will accede to this request of the Grand Rabbi, as they are themselves badly in need of money for their own immediate necessities.

The Transfer of the Medical Faculty to Stamboul.

The question has again been raised of transferring the Medical Faculty from Haidar Pasha to Stamboul. Haidar Pasha, on the Asiatic shore, though affording magnificent views and being celebrated for the quality of its country air, is too far removed from the centre of the city. The professors as well as the students find it inconvenient to spend so much time in order to attend the faculty, as they have to traverse the distance in boats by no means numerous and punctual. Besides, it is intended to increase the medical faculty by the addition of new pavilions, cliniques, wards, and for this purpose it is thought that

Stamboul will be much more suitable. Then, again, medical men have comparatively little work to do in Haidar Pasha, which is far from being densely populated. It would be altogether a wise plan if the medical faculty were removed to Stamboul.

May 24th.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

Bubonic Plague still a Menace to the Country.

NOTWITHSTANDING the successful efforts of the health authorities of San Francisco, aided by the officers of the National Public Health Service, to control the bubonic plague in that city there are evidences that the infection has been carried to different localities over a wide area by ground squirrels. Dr. Colby Rucker of the Public Health Service has been organising a scouting expedition to determine just how far the infection has spread, and preliminary reports of his work show a somewhat alarming condition, infected squirrels having been found in widely separated places in one county, with evidences that other counties are also involved. As the extermination of the squirrels is apparently impossible, the spread of the disease by the squirrels, prairie dogs, and other rodents depends solely upon whether they have sufficient tolerance to keep the bacilli alive, or whether they will die off so quickly as to prevent the germs being carried. Much blame is attached to the authorities of San Francisco for their efforts to conceal the presence of the plague long after it was identified by the sanitary officers, thus preventing active measures for its control and possible extermination at an early period.

Tampering with the New Pharmacopœia.

Physicians and druggists throughout the country are looking to the decennial meeting of the United States Pharmacopœial Convention, which is soon to meet in Washington, as the most important in the history of that organisation. This is the first meeting since the "Food and Drug Act" was passed, which adopted for all drugs used in the United States the standards of the United States Pharmacopœia that is owned by the Pharmacopœial Convention. Meeting at the same time as the Convention is its most important committee, known as the "Revision Committee," which consists of 26 of the chief pharmacists and physicians of the country, and is charged with the decennial revision of the Pharmacopœia. So far-reaching is this meeting expected to be that for months the medical and pharmaceutical journals of the country have been flooded with articles bearing on the problems to be met at this time. It has been alleged that when the Eighth Convention met in 1900 repeated efforts were made to bribe members of the Revision Committee in the interest of some particular drug or prescription, and that the temptations for unscrupulous manufacturers to repeat those methods of securing favourable mention as to their particular drugs are twofold greater now since the United States Government has adopted the Pharmacopœia standards. The chairman of the committee, Mr. Remington, of Philadelphia, spoke at a recent meeting of the Philadelphia branch of the opportunities of its members to take bribes on the occasion of the last revision; one man offered him 5000 dollars if he would change only two words in the Pharmacopœia; another man said he was willing to give thousands of dollars for changes. Professor H. H. Rushby, of Columbia University, a prominent member, says that when it was suggested about a year ago that attempts were contemplated by interested parties to obtain action at the next revision which would favour private interests, the suggestion was treated with ridicule, but it is now being repeated from various directions. A person who is exceptionally well informed affirms that the attempts to manipulate the ninth revision will exceed in strength and determination all preceding efforts combined.

Compulsory Vaccination against Tuberculosis.

At the recent meeting of the "National Association for the Study and Prevention of Tuberculosis," Professor A. S. Knopf called attention to two recently enacted State laws designed to prevent the spread of tuberculosis. The first of these is in force in Nebraska and provides that poor persons in that State suffering from tuberculosis must submit to vaccine-therapy. Professor Knopf obtained the opinions of a large number of leading physicians in regard to the propriety of this law and found that it was universally condemned. Dr. Trudeau, our highest authority on the treatment of tuberculosis, replied that it seemed to him difficult to understand how any State can make compulsory any treatment of disease, and more especially a treatment like tuberculin in tuberculosis, the benefit of which is as yet an open question, for tuberculin is not at all generally accepted by the great majority of the profession. Dr. Simon Flexner, director of the Research Institute, said that he did not believe we possessed an experimental or observational basis which suffices to justify any Federal, State, or municipal legislature in prescribing any specific treatment for tuberculosis. The second law was passed by the legislature of the State of Oklahoma, which prohibits any physician suffering from tuberculosis, however slightly, from practising his profession in that State. The law provides that every physician who applies for a license to practise in that State must make an affidavit that he is not suffering from tuberculosis in any form; that he has not in the last three years lived in the house with or nursed anyone suffering from that disease. This affidavit must be accompanied by the certificate or endorsement of a physician legally practising in Oklahoma to the effect that he has known the applicant for three years, and has made a thorough examination and has found him to be free from tuberculosis. This law was pronounced ludicrous, oppressive, absurd, incredible, and unjust by Professor Welch, Professor Jacobi, Professor Osler, Dr. Flexner, and many others from whom replies to a letter of inquiry were received.

Notable Honours to a Martyr to Science and Humanity.

Last week I mentioned the death of Dr. Howard Taylor Ricketts of Chicago, at the age of 39 years, in the American Hospital, city of Mexico, on May 3rd, from typhus fever contracted while pursuing investigations regarding the causation of that disease. He is known to have been a tireless worker, and was not in good physical condition when he went to Mexico in April to complete work which he had begun. It is believed that he contracted the disease from lice contaminated with the germs of typhus. His death caused great sorrow in the city of Mexico, especially in the Department of Public Instruction and Fine Arts and in the medical corps. I have now the pleasure of recording the fact that the President of the Republic has resolved that the following honours should be shown the memory of this heroic investigator: 1. The laboratory where he made his investigations will be named "Dr. Howard T. Ricketts Laboratory." 2. The National School of Medicine, the Bacteriologic, the Medical, and the Pathologic Institutes were put in mourning three days. 3. A special commission of those institutions accompanied the body to the railway station where a special car was provided. 4. The Department of Public Instruction and Fine Arts sent a special delegate to present to Mrs. Ricketts the expression of the Mexican Government's sorrow for the death of her eminent husband. 5. The same department sent a flower crown with this inscription, "To the heroic investigator. Dr. H. T. Ricketts. Homage of the Department of Public Instruction and Fine Arts, Mexico, May 3, 1910." The National Academy of Medicine suspended its weekly session and the President made a public panegyric on the courageous and unfortunate Dr. Ricketts.

May 19th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Plague.

THE plague returns for the week ending April 9th show that throughout the whole of India the deaths numbered 27,311, a decrease of 1182 as compared with the deaths in the previous week. The mortality in the different provinces was as follows:—Bombay Presidency, 779; Bengal, 2379; the United Provinces, 6893; the Punjab, 10,900; Burma, 422; the Central Provinces, 322; Rajputana, 2110. The worst areas in the United Provinces were Muttra district, 821; Azamgarh district, 557; Ballia district, 602; Unao

district, 480; and Etah district, 406. In the two Punjab districts of Gurgaon and Karnal the number of deaths during the week exceeded 1000.

The Health of Bombay City.

An inquiry in connexion with the prevalence of malaria in the city of Bombay is being conducted by Dr. Charles A. Bentley. It was commenced in January last, and was expected to be finished by the end of June. As the measures in progress are not likely to be completed by that time, and as it will not be possible to gauge until after next monsoon the effect of other measures independently taken by the municipality, the Port Trust, and railway companies, the Government has decided that the period of the inquiry should be extended to March 31st, 1911. The whole of the cost of this further inquiry will be borne by the Government. This week the mortality from plague has risen. The deaths are 224, as against 168 in the foregoing week. But the figures still compare well with last year's 370 and the five-yearly average, which is 583. A curious feature of this stage of the annual plague visitation is that the epidemic seems to lift first in the fort and then drift away across the north of the island. Plague in the city has been steadily declining for a month, and the increased mortality this week is almost entirely in the open districts to the north—Mahim and Worli. It is invariably so. The explanation of this curious phenomenon remains to be found. The migration of city dwellers to the suburbs for the hot weather is not sufficient to account for it. It is one of those extraordinary freaks which plague regularly performs without giving investigators a clue as to its purport. Apart from plague, the weekly health sheet of the city has no features of importance. Small-pox remains at exactly the same level as a week ago. The mortality from all diseases has risen from 813 to 890, the corresponding figure last year being 1089 and the five-yearly average 1355. The corrected death-rate is 46·42. I am glad to note that people are at last largely undergoing vaccination. The banks and large mercantile offices are leading the way. If the Government of India had acted upon the repeated advice of its health officials and enforced reasonable vaccination regulations upon the Mecca pilgrims this season, a serious contributory cause of all this trouble would have been avoided. Until some steps of the kind are taken infected *hajis* will continue to enter the city without let or hindrance, as they do now, and the inhabitants of Bombay must bear it.

The Medical Officer of Health, Mussooree.

Dr. C. Lloyd, who succeeds Dr. J. Meynell as special health officer at Mussooree, has been unable to join his post, having some three weeks ago, while dissecting the head of a dog at Bareilly, run a small bone-splinter into his hand. The brain was sent to Kasauli, and, as signs of rabies were found, Dr. Lloyd has proceeded to the Pasteur Institute to undergo treatment.

Army Dentists.

In connexion with the scheme for the employment of dentists for the army in India, the Government of India has sanctioned that headquarters of dentists for Peshawar and Rawalpindi divisions may be at Murree during the summer months instead of at Rawalpindi, and also that the summer headquarters of any of the other dentists may be varied.

April 15th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Notification of Syphilis.

AN experiment of a novel kind is to be tried in Melbourne. Acting on the advice of Dr. B. Burnett Ham, chairman of the Board of Health, the Victorian Government has gazetted syphilis as a notifiable disease within an area of ten miles from the General Post Office. The notification is to be impersonal, only the age and sex of the patient being required, and is to be made only to the chairman of the Board of Health and not to the municipal bodies. For purposes of verification of diagnosis a special laboratory will be provided at the University under the direction of Dr. Konrad Hiller, at which a Wassermann blood test will be done in every case. In order to facilitate this part of the scheme every practitioner within the metropolitan area will be supplied with apparatus for collecting specimens of blood. The schedule of conditions contains provisions requesting notification of cases of aortic aneurysm, all cases of apoplexy in young subjects, locomotor ataxia, general paralysis of insane, and cases in which a mother has a syphilitic child or suffers from two abortions or has lost three children under 5 years of age. The regulation is to remain in force for 12 months, at the end of which time an attempt will be made to estimate the prevalence of the disease. This action is the outcome of the general discussion at the last Australasian Medical Congress, in the course of which a remarkable diversity of opinion was shown amongst various sections of the profession. The specialists, and particularly the ophthalmic surgeons, held generally that syphilis was extremely common, while the physicians were not inclined to adopt such a view, nor to admit syphilis as the causative factor in many conditions which show closely identical pathological appearances. The notification scheme has also met with divided opinion and many characterise it as impracticable, and at best only likely to afford an entirely erroneous set of figures. Two objections that appear manifest will be the difficulty of preventing duplication in the notifications, and the entire reliance to be placed on the Wassermann test which is admittedly only a positive indication and liable to be affected by treatment with mercury.

Small-pox.

On the last inward voyage the Orient Company's mail steamer *Otway* reported at Fremantle a suspicious case of illness in a boy. The port authorities diagnosed the illness as small-pox and the vessel was placed in quarantine. On arrival at Melbourne five days later several other cases were developing. Several passengers had in the interim been landed at Adelaide and released on probation by the health officer of that port. Upwards of 200 persons of all classes were quarantined at Melbourne. Several new cases developed and three deaths occurred from hæmorrhagic small-pox. At Sydney about 800 persons in all were quarantined and fresh cases occurred there, one of which died from the hæmorrhagic form. A member of the crew released on probation developed small-pox and was admitted into the Sydney Hospital before the diagnosis was clear. The cases were confined to the third-class passengers with the exception of two members of the ship's company who were in contact with them. The original case was very mild. The evidence afforded by this outbreak is once more strongly in favour of vaccination. Some passengers declined to undergo vaccination, but the death of a comrade within 24 hours from hæmorrhagic small-pox shook most of their objections, and all were eventually vaccinated.

Quarantine Act.

In connexion with the outbreak of small-pox on the s.s. *Otway* it is stated that on arrival at Fremantle the port medical officer was informed that a case of tropical fever had developed on the voyage from Colombo, but examination showed the patient to be suffering from small-pox. The authorities decided to summon the ship's officers responsible for making the report, and the case is to be heard at Fremantle on the vessel's return to that port. —Dr. Lunn, surgeon to the s.s. *Fifeshire*, was proceeded against for an alleged breach of quarantine regulations. The information set forth that the breach consisted in writing "nothing" in respect to the following question: "Is there now, or has there been, on board during the voyage any person affected?" &c. The information was laid by Dr. H. R. Maclean, port health officer. The proceedings have been adjourned.

Hospital Staff Election.

The Women's Hospital, Melbourne, has followed the example of the Melbourne Hospital and abolished the system of staff election by subscribers. An electoral board has been appointed similar to that already described in the other case, and what has hitherto been a professional bugbear has been removed.

Medical Education.

There are 360 students at present studying medicine in the various years at the Melbourne University. The facilities offered by the Alfred and St. Vincent's Hospitals for clinical instruction have been eagerly accepted, and Melbourne now has three general hospitals with teaching staffs accredited by the university council.

April 27th.

Obituary.

PROFESSOR ROBERT KOCH.

GERMANY has to mourn the death of one of her greatest sons, Professor Robert Koch, who died in Baden-Baden on May 27th from arterio-sclerosis and myocarditis. This is the heaviest loss which German science has sustained since the death of Virchow, and, as in the case of that great genius, the loss is not only that of Germany but of the whole world. For Koch was not only a savant of vast renown who has contributed more than any other man, perhaps including Virchow, to raise German science in esteem, but he was also a leader in the combat against the saddest diseases which threaten the welfare of the world. Not only his country but the whole world have received the benefits of his work, so that his death will be deplored everywhere throughout the civilised nations.

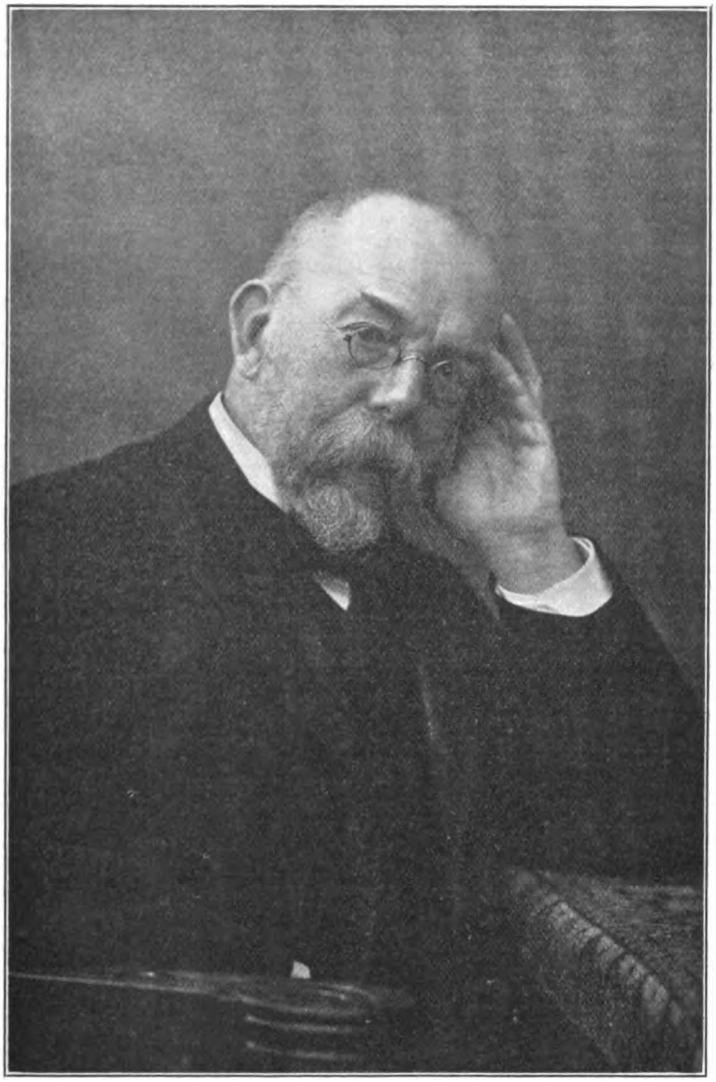
Robert Koch was born in 1843 at Clausthal, in the mining district of the Hartz mountains, where his father, who had a large family, was a Government official. He went through the medical curriculum at the University of Göttingen from 1862–66. Having graduated in 1866 he became for a short time house physician to the Hamburg General Hospital, soon afterwards settling as a general practitioner at the village of Langenhagen, near Hanover. He left this place after a certain time, and from Western Germany went to Rakwitz in the province of Posen. He then entered the Government medical service and in 1872 became appointed district officer of health in Wallstein, province of Posen. He stayed there from 1872 to 1880, and it was in this, one of the remotest districts of Germany, and far from the centres of scientific life, that he began his researches in bacteriology which were to become of fundamental significance in the development of medicine and hygiene. It is reported that at this time his means were too small to allow him to buy a modern microscope, and that his wife exercised the strictest domestic economy until she had collected the necessary sum and was able to give her husband as a birthday present the instrument so much desired by him. Following the way of the great French savant Professor Pasteur, he improved greatly the methods of technique. It is his system of solid nutrient media by which bacteriology made its enormous progress since 1876.

The results of his work were first shown in his researches on the etiology of anthrax, a subject which had also been investigated by Pasteur. By his method he was able to show the bacillus which was the real and exciting cause of anthrax, and demonstrated that the three classic demands ("Koch's postulates") required as a proof of the causal relations of a germ were fulfilled by that micro-organism—namely, that it was present in each case of the disease; that it was possible to cultivate it outside the body; and that the inoculation of such cultures produced the same disease. So the etiology of anthrax was brought from the stage of conjecture to that of certainty, and when Koch had finished his researches he decided to show his preparations to competent critics. He went to the nearest university town, to Breslau, where the great botanist, the late Professor Ferdinand Cohn, lived. It is reported that Cohn at once recognised the enormous value of the methods devised by a hitherto unknown medical officer of health of a small country place, and that he became so excited that he sent a messenger to the Pathological Institution asking the professor of pathological anatomy and his assistants to leave their work and "come here at once, for there is with me a young medical officer of health from the province of Posen who shows us things from which a new epoch of biology will be dated." It was in the "Beiträge zur Biologie der Pflanzen," edited by Professor Cohn, that his first work was published, not in a medical but in a botanical journal. In that essay he described the cultivation of the bacillus; he stated that the latter produced spores which are much more resistant than the bacillus itself, and that the greater or smaller infectivity of material containing the bacillus depended on the presence or absence of spores.

In 1878 his work on Wound Infections was published, and in it a scientific explanation and justification were given of the antiseptic method devised by the genius of Lister. At this time surgical opinion was not solid in favour of the antiseptic doctrines, strange as the fact may now appear, so that Koch was displaying a bold capability of judging where the truth lay when he became a champion of Lister in Germany. But in 1880 a new epoch of life began for him, as he was called to Berlin to be a member of the Imperial Health Office. His first official work was concerned with improving the methods of disinfection. Here he recommended the use of the Abbé condenser for bacteriological research, and so greatly improved microscopical technique. But very soon he began to study a disease in which he continued to be interested during his whole life—namely, tuberculosis. It was inevitable that such a man in a bureau of public health, with mortality statistics before him daily, should see in the solution of the problem how to prevent tuberculosis the greatest exploit open to the physician and sanitarian.

In 1882, as every medical man knows, he took the medical world by storm, for he read a paper on the Etiology of Tuberculosis, wherein he stated that the disease was an infectious one and was caused by a bacillus. It was again his technique in the matter of staining which enabled him to discover the bacillus of tuberculosis, and his demonstration and description of the relation of this bacillus to the tuberculous lesions met with in man and animals were without flaw. He succeeded in proving the presence of this bacillus in tuberculous tissues, but beyond this he was able to make pure cultures of the micro-organism on artificial media, an exploit hitherto impossible, and with the pure culture so obtained to inoculate healthy animals and in them to produce a series of tuberculous lesions indistinguishable from those from which the tubercle bacillus had been isolated. In publishing these results Koch maintained that the tuberculosis of animals corresponded in all essential features and details with the tuberculosis met with in the human subject, and that any differences occurring were those of degree and not those of kind. Indeed, so firmly was he convinced of this unity of type that later in the production of the "tuberculin" with which he essayed to treat tuberculosis in the human subject, and subsequently to make a diagnosis of this disease in cattle, little or no attempt was made to draw any distinction between the tubercle bacillus of human origin and that derived from a bovine source. Each seems to have been regarded as of equal value as seed material from which to grow the culture through the medium of which the tuberculin was produced. The luxuriance of the growth rather than its source was the factor that received attention. The method by which he demonstrated the tubercle bacillus in films and in sections was by staining them with a solution of methylene blue made alkaline by caustic potash and counterstaining with vesuvin. He found that organisms other than the tubercle bacillus and the organism of leprosy were decolourised by the vesuvin, and that in stained specimens the tubercle bacilli appeared as blue rods on a brown ground. He introduced the method of culture on solid media and succeeded in growing the tubercle bacillus on the serum of the ox. He was able to produce tuberculosis in animals by inoculation of pure cultures. He showed that the bacilli were killed in a few minutes by direct sunlight and by diffused daylight in a few days. The specificity of Koch's bacillus is now so established that we have some difficulty in realising the opposition which his views created. But his discovery was so astonishing, and so at variance with old and accepted views, that it required more imagination than the average man of science could muster up before he could follow the doctrine of the great discoverer and realise all that it might mean. In the case of the anthrax bacillus Koch made his views known primarily to a botanical society: now he made no widespread *communiqué* to medical men at large with regard to his pregnant discovery, but first read a paper before the important but relatively small Physiological Society of Berlin, then presided over by the celebrated physiologist, Professor Dubois-Reymond. The greatest excitement followed, for by this discovery Koch, who was hitherto known in the scientific world only, became at a bound one of the most-talked-about men not only in Germany but in the world. The discovery of the specific germ of anthrax had its valuable sides, both scientific and commercial, but the discovery of the tubercle bacillus meant a new era in the combat against one of the most terrible foes of humanity. The popular fame was well deserved, for it is unnecessary to explain to the medical

reader that everything done since to cure tuberculosis and to avoid the spread of the disease—the system of sanatoriums, the German system of insurance, the movements for healthy housing, as well as every specific treatment—has its primary origin in the discovery of the tubercle bacillus. His country was prompt to see the enormous value of his work and Koch was raised to the position of a Privy Councillor.



But Koch was not the man to limit his work to one field because in that field he had astonished the world. In 1883 the German Government asked him to inquire into the causes of the enormous spread of cholera in Egypt and India, by which Europe was also threatened. Together with his assistants, Dr. Gaffky and Dr. Fischer, Koch went to Egypt, but after a stay of a few weeks found that he must go to the apparent place of origin of the epidemic if his inquiries were to be thorough, and therefore left for India. Here the practical support of the Indian Government was at once granted him, and by careful observation of the course of different epidemics he came to the conclusion that the disease was spread by the water and that the exciting cause must be found there. In the water of a tank in Calcutta he discovered a bacillus which was present both in the intestinal tract of cholera patients and of persons who had died from cholera. The bacillus, the comma bacillus, was not found in the bodies of those who had died from other diseases, and although Koch's chain of evidence was incomplete—he was at first unable to produce cholera by transferring the bacillus to animals—he did not hesitate to suggest that the comma bacillus was the cause of the disease. Later he found that his attempts to transfer the disease had failed because the acidity of the gastric juice destroyed the virulence of the bacillus, but if the gastric juice was neutralised the bacillus produced cholera. The doubts as to the virulence of the bacilli were thus removed, and the Government recognised the great merits of the research by a reward of M.100,000 (£5000), which was unanimously voted by Parliament. It was a result of Koch's discovery that an international conference to consider the prevention of cholera was convoked in Berlin, and that the mutual notification of cases, the examination of the water of rivers coming from infected countries, and the provision of efficient waterworks became the principal means of prevention, instead of quarantine, separation of infected localities, and other of the accepted measures. A few years later Professor Koch had ample opportunity to verify the exactness of his views when the great cholera epidemic broke out in Hamburg,[1] and the infection was found to be due to the fact that by the carelessness of the local authority water from the infected river was allowed to be used in the waterworks.

On his return from India the Government desired to give him more opportunity for scientific work than he had hitherto had in his position as a member of the Imperial Health Office, for he had there to do official work which did not always suit him; besides it was desired to bring him more into touch with the students and the younger medical generation. Therefore in 1885 he was appointed professor of hygiene and director of the new Hygienic Institute in connexion with the University of Berlin, but the academic duties took so much of his time that he resigned his post in 1891, when a special appointment was found for him in the Royal Institute for Infectious Diseases. This institution provided him with ample and well-fitted laboratories and a hospital, and he here made his famous attempt to complete his work on tuberculosis, formulating a method for destroying the organism which he had discovered to be the cause. At the International Medical Congress held at Berlin in 1890 he delivered an address on tuberculosis wherein he first alluded to a new remedy against the disease, but declared himself unable to give more ample information because his experiments were not yet finished. Contrary to his original plan, Professor Koch was, however, induced by his friends and by the leading members among various sanitary authorities to publish an account of the new remedy which he had devised—tuberculin—and accordingly in the issue of the *Deutsche Medicinische Wochenschrift* for Nov. 4th an explanation of his curative method appeared. It must always be remembered that early publicity formed no part of his own intentions, but notwithstanding his usual caution he declared in that article that he believed that commencing tuberculosis could be surely cured by the administration of the new compound. His views were confirmed by the authorities of certain hospitals where he had treated patients, though Virchow opposed them from the beginning. The news of Professor Koch's words caused the greatest possible sensation in both medical and lay circles throughout the world, and the opposition of some of his colleagues produced the less effect that previously Koch's work in respect of cholera had been bitterly criticised by Pettenkofer, and afterwards proved correct. The stock of the new remedy was soon exhausted owing to the enormous demand on behalf of medical men and of hospitals on every side. And a rush began to Berlin of tuberculous patients from all parts of Europe and America who, many of them in a desperate state, had made the long journey to Berlin. "I remember very well," writes our Berlin correspondent, "the types of patients from southern countries who even to an unexperienced eye, as mine then was, appeared quite hopeless, but had nevertheless come, many without adequate clothes even, to face the raw winter of Northern Germany." Fortunately, this frantic rush for health was of rather short duration; it was soon found that the reaction caused by the tuberculin made the patients too weak to allow treatment to be continued, and whilst in many cases no improvement was observed, the number of unexpected deaths awoke the suspicions of the medical profession that the new remedy was not practically effective. Then a serious blow was given to the method by Virchow. In a demonstration before the Medical Society of Berlin Virchow showed specimens of lungs of tuberculous patients who had undergone the treatment, when he declared that during all his work as a pathologist he had never seen such cases of "*foudroyant*" spread of miliary tuberculosis. By and by other undesirable complications were reported, and the tuberculin, which later on was much improved by Professor Koch, nearly fell into total disuse. Although the practical results were so unhappy Professor Koch's tuberculin nevertheless means the first attempt at a specific and rational treatment of tuberculosis.

The prestige attaching to his name undoubtedly raised hopes in the minds both of medical practitioners and of the general public to an unduly high pitch, and there can be no doubt that harm was done by the indiscriminate use of the remedy. In a leading article published in THE LANCET[2] shortly after the announcement by Professor Koch of his remedy, we expressed the sentiment of British pathologists in deprecating the early publication of his researches, and we pointed out that although this was in some sense forced on him the responsibility must be laid at his door. We also inveighed against sending patients to Berlin during the winter before the efficacy of the treatment was established. Shortly afterwards the nature of the treatment was disclosed, and it proved to be the substance which has since been called original tuberculin, or old tuberculin. It was prepared from a culture of the tubercle bacillus in glycerine veal broth of 6 to 12 weeks' growth, by evaporation to one-tenth of its bulk and filtering off the bacilli by porous porcelain. It was, in fact, a solution in glycerine of the extra-cellular toxins produced by the tubercle bacillus. Owing to the doses in which it was employed harmful results were not infrequent, and various commissions, notably one from the Paris hospitals, sent to report upon its value expressed themselves unfavourably, and it was soon discredited. The febrile reaction obtained in tuberculous patients after its injection proved, however, to be of great diagnostic value, and it was extensively used for this purpose both in man and animals. The failure of tuberculin as a curative agent at its first introduction, and the disappointment thereby caused, led on the one hand to a general neglect of its use except for diagnostic purposes, especially in this country, and, on the other hand, to a general condemnation of Koch for the premature announcement of his remedy. Some observers, especially in Germany and America, however, continued to use it, employing smaller doses, and Koch himself never lost faith in the theories upon which his remedy was based. He continued in spite of much other occupation steadily to work at the production of tuberculin, and in 1897 introduced some modified forms for which he again claimed curative properties. Of these the most

[1] THE LANCET, Sept. 30th (p. 828), and Oct. 7th (p. 891), 1893.

[2] THE LANCET, Nov. 22nd, 1890, p. 1107.

HIS EXCELLENCY ROBERT KOCH,
HON. PROFESSOR OF THE INSTITUTE OF INFECTIOUS DISEASES, BERLIN; PRIVY COUNCILLOR OF THE GERMAN EMPIRE; F.R.S.
(Reproduced from a photograph from Messrs. Speyer and Peters, Berlin.)

important was that known as new tuberculin, or T.R.; this consists of an emulsion prepared from living virulent strains of human bacilli. They are dried, ground to powder, extracted with water to remove the soluble toxins, and the residue is emulsified with water and preserved by the addition of glycerine. Later, a further modification known as "Bacillen emulsion," or B.E., was introduced, consisting of an emulsion of powdered bacilli in distilled water and glycerine; the heavier particles are allowed to subside, the supernatant liquid being standardised. These forms of tuberculin, as well as the old tuberculin, are now extensively employed in the treatment of localised tuberculosis, but the dosage is now more carefully graduated, especially since the researches of Sir Almroth Wright on the opsonic index, as a result of which a very great reduction in the size of the dose has occurred, at any rate, in this country. Numerous modifications of tuberculin have been introduced by various observers, and the number is constantly increasing. That tuberculin may be of value in treatment as well as in diagnosis is now definitely established, but the limitations of its usefulness have not yet been clearly worked out and the time is not yet ripe for an estimate of its exact value in treatment.

The renown of Professor Koch was not in the least affected by his practical unsuccess in the combat against tuberculosis. This fact, which forms a wonderful testimony to the general belief in his absolute honesty, is shown by the fact that in 1897 the British Government asked him to proceed to Cape Colony to investigate the rinderpest prevalent in South Africa. He did so, and recorded that the blood of cattle which had recovered from an attack of rinderpest had an immunising action for other cattle, and that by preventive injections the spread of the disease might be avoided. In 1897 he studied plague in India. In 1898 we find the great *savant* again absent from Germany, this time at the request of the Italian Government, who invited him to Italy to assist in the study of malaria. He made no particular contribution to our knowledge in this now well-tilled field of pathology, but in the same year proceeded again to Africa, this time on behalf of the German Government. His study of tropical malaria in the German colonies confirmed conclusions already arrived at by British investigators—viz., that malaria is spread by mosquitoes. He suggested as a plan for the treatment of malaria that quinine should be given when the blood contained the ring-shaped organisms. In the course of this extended tour he also made interesting suggestions with regard to the remedial treatment of sleeping sickness by the arylarsonates.

In 1901 Professor Koch was present at the British Congress on Tuberculosis, where he greatly disturbed the scientific world by announcing a new theory that human and bovine tuberculosis were separate and distinct and that bovine tuberculosis could not be conveyed to man, a theory which was vehemently combated by most other prominent pathologists. In his original paper in 1882 Koch affirmed that human tuberculosis and the bovine disease, to which in Germany the name of *perlsucht* is applied, were identical, and we have said that in devising his remedy eight years later he clearly had the same opinion still. His address before the International Tuberculosis Congress, in which he maintained that the two conditions were distinct, and brought forward evidence that bovine tuberculosis was not communicable to man, and conversely that the bacillus of human tuberculosis was not pathogenic for bovines, was therefore at variance with his original theories. His pronouncement, made when measures were in preparation in this country for the control of the supply of meat and milk to avoid infection by tubercle, was received with amazement and almost with consternation. Lord Lister, presiding at the meeting before which the address was delivered, while paying due tribute to the authority of Professor Koch, referred to the possibility of modification of the organism by passage through different animals, and advised that care should be taken to wait for confirmation of the views expressed by Professor Koch before neglecting precautions in regard to tuberculous meat and milk. It must in fairness to Koch be pointed out that his statement on this occasion has usually been exaggerated, but accepting it in its most limited sense, those who heard it could not but be anxious as to the effect such a pronouncement would have on the public mind. Not only was one great source of tuberculous infection discredited, and therefore to be ignored, but if a mistaken idea concerning it had been harboured all these years, were not those who were now being harried to take precautions against the spread of infection through the agency of the bacillus from the human source justified in asking that some check should be put on the action of those experts who had now been deserted by their own high priest? The evidence on which the statement was founded was, moreover, not of the same weight, either as to character or quantity, as that usually offered by Koch in support of his theses; it was scrappy and incomplete, and certainly did not accord with what had been observed by those who had been working at the subject in this country, or in the United States, where Dinwiddie and others had indicated that there was probably some difference in the infective power or virulence of the bacilli cultivated from the lesions of different species of animals.

The matter was so important that steps were taken at once to secure the appointment of a new Royal Commission on Tuberculosis, although several other commissions had already reported on this or closely allied questions. The intense anxiety felt by all those interested was the greatest compliment that could be paid to Koch's power and personality. The dictum of no other man could have received a tithe of the consideration or excited a fraction of the concern accorded to or raised by this pronouncement. Workers in all parts of the civilised world have examined the evidence on which it was based, and have laboriously collected fresh evidence—clinical and experimental—which might have any bearing on this question. Belgium, Holland, France, Germany, the United States, and Japan, each has contributed its quota of facts and opinions; the British Royal Commission has issued interim reports, and all agree that the sharp line drawn by Koch between the "human" and "bovine" tubercle bacilli does not exist. That there are differences in the behaviour of bacilli from different sources most observers are agreed, but that the diseases produced by them are intercommunicable between man and the lower animals there is now little doubt. The work of the British Royal Commission has demonstrated that there are two types of tubercle bacillus, a human and a bovine, differing slightly in biological and morphological properties and in pathogenic activities. The human bacillus is more pathogenic for man, but can be inoculated into bovines, although the lesions produced are less extensive and of slower growth than those produced by the bovine type, and they show a tendency to spontaneous cure. The actual transmission of the bovine bacillus to man cannot, of course, be put directly to the test, but there seems no doubt that in some cases of human tuberculosis the organism found is of bovine type. The actual relation of the two types to one another cannot be said to be definitely settled, although the general consensus of opinion seems to be that they are the same organism modified by change of host. Koch entered into the controversy from time to time with some acerbity, and even at the last congress at Washington in 1908 he endeavoured to uphold his thesis, but he appears latterly to have slightly modified his position.

Koch was a man of strong convictions, and he fought strenuously against the acceptance of doctrines opposed to his own, but at the Washington Conference on Tuberculosis he announced that he should devote the remainder of his energies to probing this question to its root. He declared that until he could satisfy himself that the bovine type of bacillus could be demonstrated as the only form occurring in the lungs of a certain number of tuberculous human patients he should remain convinced of the general correctness of his earlier position. During the latter part of last year and the earlier part of the present year he was engaged in drawing up a plan of campaign, the outcome of which all hope will still be published.

In both the instances referred to, for which Koch has received much censure and criticism, it will be seen that there was in the main a large substratum of truth and that Koch erred less in his observations than in the premature publicity which he gave them, or in the too wide generalisations which he drew from them. Tuberculin has established itself as a curative or remedial agent, used in different doses from those in which Koch employed it. Bovine and human tuberculosis are now recognised as differing in important details, but that there is a danger to man in the

prevalence of tuberculosis among bovines is now generally admitted, and tuberculous meat and milk must be dealt with accordingly. The relative frequency of bovine and human infection in man is not yet settled, but the risk of bovine infection is a real one and must not be disregarded as Koch suggested.

The strenuous life and the exacting work in tropical climates had until recently not prejudiced his health, but in the last winter symptoms of cardiac failure developed. Professor Kraus, who was consulted, found that myocarditis was present, and advised his patient to abstain from work. He did so, but severe attacks of angina pectoris led to ever-creasing weakness. Ten days ago he was apparently so much better that his friends decided to convey him to a sanatorium in Baden-Baden. There he died on Friday, May 27th, in the presence of his wife and of his medical attendants.

In 1905 Koch received the Nobel Prize and delivered a lecture entitled, "How the Fight against Tuberculosis now Stands,"[3] at Stockholm on Dec. 12th, 1905. The contributions made by this remarkable man to the study of rinderpest, sleeping sickness, blackwater fever, plague, and malaria have only been briefly alluded to; their importance is slight compared with his work in connexion with anthrax, cholera, and tuberculosis. The special characters of his work throughout his strenuous life were its practical aim and the zeal and enthusiasm with which it was carried out. It was precisely these characters which led him to the errors which he made and which conduced also to the widespread value of his work. Consider, for example, Koch's work in connexion with surgery, though Koch himself was a physician and a bacteriologist. Great though the effect of the discovery of the tubercle bacillus on medicine was, it may well be doubted whether it was not greater still on surgery. So long as it was not recognised that there was a specificity in tuberculous lesions, so long confusion was inevitable in their classification, in their recognition, and in their treatment. The ill-defined term "scrofula" was conveniently, if indefinitely, applied to many conditions, some of which were tuberculous and some were not, and Koch's discovery of the tubercle bacillus soon made itself felt in the nomenclature of these conditions. The term tuberculous was more freely applied and the term scrofulous was less and less used, until now it is hardly employed at all. It was seen before long that there was an etiological relation between what may be termed surgical manifestations of tuberculosis and tuberculous disease of the meninges or the lungs, and that the removal of tuberculous foci diminished the risk of tuberculosis of internal organs. The invention of tuberculin, both of the original form and of the later modification, has not been without a marked effect on surgical practice. The diagnosis of tubercle, which previously had to wait until a portion of the body had been removed or until death had occurred, could after the advent of tuberculin be determined with a very close approach to certainty during the patient's life, though in many cases it is not considered necessary or advisable to employ it.

Although Robert Koch was an untiring worker in regard to infections other than tuberculosis, it is more especially by his remarkable and epoch-marking researches in connexion with the pathology, bacteriology, and treatment of this disease that his name has become so widely known throughout the civilised world. It is no exaggeration to say that since his discovery and isolation of the tubercle bacillus in 1882 Koch has dominated the whole field of research in regard to tuberculous disease. Laennec, by his introduction of the stethoscope and by his masterly clinical and pathological studies, gave an impetus to the study of pulmonary tuberculosis, which led to the researches of the morbid anatomists of the middle of the nineteenth century whereby the characters of tuberculous and of the so-called scrofulous lesions were defined. The controversy as to the specific character of these conditions raged until the ingeniously conceived inoculation experiments of Villemin in 1865 afforded strong presumptive evidence in favour of specificity. The absolute proof of this was afforded by the work of Koch published in 1882. This research must take rank as one of the most striking in the whole field of medicine and will remain as a model of accuracy and completeness. Not only did Koch isolate the tubercle bacillus and demonstrate its presence in the lesions of man and animals, but he also perfected culture methods, succeeded in growing the organism in pure culture, and in producing tuberculous lesions in animals by inoculation. The criteria or postulates which he enunciated as to the specificity of a micro-organism in relation to a disease have become classical. Improvements in technique have been introduced, but few, if any, of his statements then made have had to be modified, and it is impossible to read the account of his researches without admiration for the masterly way in which they were conceived and executed. Although his merits have been recognised during his life, and although he has received his share of reward and recognition, it is probable that history will accord him an even greater meed of praise than his contemporaries have done, for the results of his work have not yet fully matured. His life and record will render his name undying, and Germany may well be proud of one of her sons who takes rank beside Virchow, Lister, and Pasteur, and whose loss the whole profession of medicine in all countries mourn.

His personal characteristics of courage, acuteness, industry, and perseverance are so displayed, even in the necessarily brief biography which we have given, that no stress need be laid upon them. In private life he was, like other great men of his kind, of a retiring disposition. Solemnities and celebrations he abhorred, and although he was covered with honours and titular distinctions in his own country and abroad, he never can be said to have sought any such recognitions; they followed directly upon his work. He was twice married, on the second occasion when he was 50 years of age, his young wife accompanying him upon one of his African tours. She and his daughter complete the immediate family circle which mourns him.

[3] THE LANCET, May 26th, 1906, p. 1449.

RUSSELL STEELE, M.D. DURH., M.R.C.S. ENG., L.R.C.P. EDIN.,

CONSULTING SURGEON, WEST HERTS COUNTY HOSPITAL.

THE news of the death of Dr. Russell Steele, which occurred at Hemel Hempstead on May 18th, will be received with regret and sorrow by his many old friends and patients. Born in 1847 at Reigate, where his father, Dr. John Sisson Steele, practised for many years, he received his education at Epsom College, and from there went in 1865 to study medicine at University College, London, where he was a contemporary of Sir Thomas Barlow. After leaving University College, he was for a few years an assistant to his father, and in 1877 settled at Hemel Hempstead, first as assistant to Dr. Holland Ambler, and on Dr. Ambler's death in 1879 as partner with his son Mr. Horace E. Ambler. Of his career at college and afterwards, Sir Thomas Barlow writes: "Russell Steele was well known to me because we were fellow students. He was a very engaging man, popular, and much liked by all his fellows. He went to the country directly after he had qualified, and I often saw cases with him at Hemel Hempstead. He was always the same—devoted to the interests of his patients and disregardful of his own. He was a careful, accurate, and thoughtful practitioner, and seemed to me to keep thoroughly abreast with the progress of modern knowledge. No wonder he was beloved by his patients, for he was always tender-hearted and humane, and he was a delightful companion, for he had a cultured taste and keen appreciation of beautiful things. Nobody could have been more patient, gentle, and unselfish all through his long weary illness." In his hospital work, where his services were much appreciated by the staff and committee as well as by his patients, Steele took unremitting interest, and showed himself a skilful surgeon. Quiet, unassuming, and self-sacrificing, he was a fine example of the general practitioner of this country, and did much good in upholding the honour of his profession. Nothing gave him greater pleasure than to meet his school and college friends and to discuss old times. For Epsom College he retained to the last days of his life a great affection, and in its welfare he took a keen interest. The funeral service was held at the parish church on May 21st, the building being filled to overflowing by those who loved and respected him, by many of whom he will be sadly missed. He leaves behind him a widow, three sons, and two daughters to mourn their loss.

GEORGE WOLSTENHOLME, M.D., C.M. GLASG., J.P.

WE regret to announce the death of Dr. George Wolstenholme, which occurred recently at the house of his sister in Blackpool where he had gone for rest and change. The deceased, who was 55 years of age, was born at Oswaldtwistle, where he spent his youth and received his early education. He then proceeded to the University of Glasgow and in 1881 obtained the degrees of M.B. and C.M. After acting as an assistant and also performing locum-tenent work for some time, he settled down in Newtown, Pemberton, which is now annexed to the county borough of Wigan, and rapidly built up a large general practice. Amidst his busy life as a practitioner he found time to devote a useful share of time to public aims. He had been a member of the urban district council, and after the amalgamation of Pemberton with Wigan he successfully contested a ward more than once, and latterly refused an aldermanship. At the time of his death he was chairman of the sanatoria subcommittee and vice-chairman of the health committee. In 1905 he was made a justice of the peace, and was most conscientious in the discharge of his duties. He was very popular alike with his patients and with his professional brethren, holding at one time the office of president of the Wigan Medical Society. A conscientious practitioner who considered the welfare of his fellow men before himself, he unfortunately, through his multifarious duties, contracted influenza on two occasions which undermined what was previously a healthy and sound constitution, and he succumbed to gastric and intestinal trouble. He was interred in the family vault at the Mount Pleasant Wesleyan Chapel, Oswaldtwistle.

WILLIAM HOWELLS RIX, M.R.C.S. ENG., L.S.A.,
CONSULTING SURGEON, TUNBRIDGE WELLS GENERAL HOSPITAL.

THE death occurred at Tunbridge Wells, on May 24th, of Mr. William Howells Rix, a well-known member of the medical profession. As far back as 1858 he became a Member of the Royal College of Surgeons of England, and a year later took the diploma of L.S.A. He was at one time house surgeon at the Middlesex Hospital, London, but eventually settling down at Tunbridge Wells, he soon acquired an extensive practice. He became attached to the surgical staff of the Tunbridge Wells General Hospital and, at the time of his death, at the age of 74, he was consulting surgeon at that institution. Mr. Rix took a great interest in educational matters and was a governor of a Nonconformist school at Tunbridge Wells.

FREDERICK CHARLES HITCHINS, F.R.C.S. EDIN., L.R.C.P. LOND., M.R.C.S. ENG.

THE death is announced of Mr. F. C. Hitchins, which took place at his residence, Trevarrick, St. Austell, Cornwall, on May 8th, in his 39th year. He was the third son of the late Mr. T. H. Hitchins of St. Austell, and received his medical education at Guy's Hospital. In 1897 he obtained the double qualification of the English Conjoint Examination Board, and eight years later—namely, in 1905—became a Fellow of the Royal College of Surgeons of Edinburgh. After holding the appointment of assistant house surgeon at the Royal Hants County Hospital, Winchester, he successively became house surgeon at the Stamford and Rutland General Infirmary, the Bradford Children's Hospital, and the South Devon and East Cornwall Hospital, Plymouth, and later commenced practice at St. Austell, where he soon became known as an operating surgeon, not only in the town where he lived but also in the district around. In the short period of about five years during which he practised at St. Austell he became extremely popular and highly respected. He was much sought in consultation by his professional *confrères*, who had a high opinion of him. He leaves a mother, brother, and sister, for whom much sympathy is felt. The funeral, which took place on May 11th, was largely attended, amongst those present being several members of the local medical profession.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Professor Robert Koch, the eminent bacteriologist of Berlin.—Dr. Howard T. Ricketts, adjunct professor in the Rush Medical College, Chicago.—Dr. Josef Grünfeld, *privat-docent* of syphiligraphy in Vienna.—Dr. F. Tilden Brown, professor of genito-urinary diseases in the Bellevue Hospital Medical College, New York.—Professor Eduard von Beneden, the eminent zoologist and embryologist, has died in Liège.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* The number of women medical students in Berlin and the other Prussian Universities was 266 during the past winter session, being a considerable increase over the number in the previous winter, 188.—*Budapest:* Dr. Hugo Feleki, Chief Surgeon of the General Polyclinic and well known for his writings on urinary diseases, has been granted a title of Hungarian nobility. Dr. Toth, *privat-docent* of Gynæcology; Dr. Török, *privat-docent* of Dermatology; and Dr. Verebély, *privat-docent* of Surgery, have been promoted to Extraordinary Professorships. Dr. Béla Alexander has been recognised as *privat-docent* of Radiography and Dr. Lénart as *privat-docent* of Laryngology.—*Clausenburg:* Dr. Heinrich Kanitz has been recognised as *privat-docent* of Dermatology.—*Halle:* Dr. Grund has been recognised as *privat-docent* of Medicine.—*Vienna:* Dr. Rudolf Poech, the eminent traveller, has been recognised as *privat-docent* of Anthropology.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on May 26th, with Dr. F. H. Champneys in the chair.—The following resolutions were put from the chair and passed:—

That this Board begs humbly to offer to His Majesty the King its deep sympathy in the grievous loss which he in common with the Empire has sustained by the death of His late Majesty King Edward VII.; and to tender at the same time its loyal congratulations upon His Majesty's accession to the Throne, and the expression of its hope that His reign may be long, peaceful, and happy.

That this Board begs humbly to offer to Her Majesty the Queen-Mother its heartfelt sympathy in the affliction which has befallen her, and to assure Her Majesty that the effort made by His late Majesty King Edward VII. and Herself to alleviate the condition of the poor and suffering amongst their subjects will not be forgotten by those whose work has, in its degree, the same objects.

—A letter was received from the clerk of the Privy Council as to the Board's resolution of April 21st, proposing to admit to the Board's examination without requiring further training candidates holding qualifying certificates under Section 2 of the Midwives Act, 1902. The Board decided that, in consequence of the opinion expressed by the clerk of the Council as to the competence of the Board to pass the resolution referred to, no action be taken by the Board thereon.—A letter was received from the clerk of the London County Council stating that in the opinion of the Council there is no necessity within the County of London for admitting to the Midwives Roll anyone who does not possess a certificate of training in midwifery.—A letter was received from the Bolton Midwives' Association asking the Board not to admit to the roll under Rule B 2 anyone resident in Bolton unless qualified by examination.—A letter was received from a certified midwife inquiring as to her obligation to undertake a case for which she had been engaged, but to which she was not summoned until four hours after the baby had been born. The Board decided that the midwife be informed that she has infringed no rule of the Board in declining to undertake a case in the circumstances.—Dr. Champneys having detailed the complaint made by Dr. H. Scurfield, medical officer of health for the city of Sheffield, received by the Board on April 21st, as to the practice of unqualified male midwives, it was decided to make representations to the Privy Council as to the desirability of amending the law so as to prevent the practice of midwifery by unqualified men.—On consideration of further correspondence as to alleged irregularities in training at the Royal Derby and Derbyshire Nursing Institution, the Board decided that pupils from the Royal Derby and Derbyshire Nursing Institution who present schedules, duly filled up and signed by competent authority, may be admitted to the June examination of the Board; and that, if it is desired that pupils should continue to be trained at the Royal Derby and Derbyshire Nursing Institution, application must be made by the medical practitioner who delivers the

lectures on the prescribed subjects for recognition as a teacher, and by the chief midwife for approval for the purpose of supervising the practical work.

THE visit of the Irish Medical Schools' and Graduates' Association to Bath, which was postponed in consequence of the lamented death of H.M. King Edward, has now been definitely fixed for June 18th, 19th, and 20th.

DONATIONS AND BEQUESTS.—Sir Julius Wernher has made a donation of £1000 for the endowment of a bed in response to the special £10,000 appeal for University College Hospital.—The Dreadnought Hospital, Greenwich, has received a donation of £251 2*s.* 4*d.* (2000 tls.) from the Imperial Chinese Government in recognition of services rendered to sick and injured Chinese sailors.—The late Mr. Henry Rothwell Daglish, of New Romney, Kent, has left by will £2000 to Guy's Hospital.

A SCHOOL FOR MOTHERS IN MANCHESTER.—A largely attended meeting was held in the Manchester town-hall on May 30th, under the presidency of Mrs. Charles Behrens, the Lady Mayoress. The object of the meeting was to bring the School for Mothers more prominently before the public. The Lord Mayor, Mrs. Pember Reeves, Dr. J. Niven, Dr. A. Hutton, Dr. T. Arthur Helme, Mrs. Eckard, chairwoman of the Manchester Mothers' Guild, and others were present. The Lady Mayoress said that one of the chief causes of a high infantile mortality is the ignorance of mothers. At school no provision has been made, until quite recently, for the practical teaching of hygiene, while at home, in most cases, the mothers are as ignorant of such things as their children. The Ladies' Health Society, a branch of the Manchester and Salford Sanitary Association, which works under the supervision of the medical officer of health, has formed the Mothers' Guild and the School for Mothers, "to check the high rate of infantile mortality by providing meals at low charge to expectant nursing mothers, by giving instruction in the care and feeding of infants, in general hygiene, and by other means." Dr. Hutton said that philanthropic work had been directed to helping those already weak, but "they were now helping the child to come into the world healthy and to keep it healthy." Mrs. Pember Reeves, an active worker in the "Mother and Baby Club" in Lambeth, said that poverty and not intemperance or thriftlessness was the great difficulty. Dr. Niven and Dr. Helme also spoke in favour of the movement.

THE CHILDREN'S COUNTRY HOLIDAYS FUND.—Of the many societies which help the poor none perhaps give more satisfaction to both giver and receiver than those which provide country holidays for the children who live in the poorer quarters of our large towns. In such a holiday the child is placed in an environment which promotes its health and happiness, and the donor experiences the satisfaction of having helped someone who really needs help. The nation is also benefited by the children, who are citizens in the making and the fathers and mothers of the coming generation, being healthier physically and morally. The undoubted good result which must have followed the sending away last year of 43,582 poor children in the country for a fortnight by the Children's Country Holidays Fund can best be understood by reading the very interesting reports of the various district committees which are contained in the annual report of the Fund, and the extracts from the children's letters to their friends, which, while revealing the pathetic conditions under which many of the children live, show by their naïve phraseology how their minds are expanded by their new and often, to them, strange environment. "It is easier to be clean and truthful in the country" is one extract which, at any rate, shows a keen appreciation of the difference in the child's surroundings; and there are many other examples which afford food for reflection on the part of those who cannot fully appreciate conditions of life foreign to their own environment. The work of this society increases year by year, 1000 more children being sent away in 1909 than in 1908, and financial help is greatly needed. The average cost of a fortnight's holiday, including all expenses, is 14*s.* 8*d.* per child, and towards this the parents contribute an average of 4*s.* 7*d.*, the society paying the balance of 10*s.* 1*d.* The expenditure of the fund last year was £31,952, and the parents' payments amounted to £9597. Messrs. Barclay and Co. are the bankers of the fund, and contributions may be sent either to the honorary treasurer, the Right Hon. the Earl of Arran, or to the secretary, Mr. W. R. L. Blakiston, at the Central Office, 18, Buckingham-street, Strand, London, W.C.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—A council meeting of this association was held in London on May 25th. Dr. F. G. Crookshank presided over a good attendance. Mr. D. A. Belilios (honorary secretary) reported the accession of new members, and Mr. E. G. Gibbs-Smith (honorary treasurer) a satisfactory increase in subscriptions and balance. A letter was read from the general secretary of the British Medical Association giving consent for a general meeting to be held in London during the approaching annual meeting of the British Medical Association. It was agreed to arrange for the meeting to be held on Friday, July 29th, to be followed by a dinner. The provisions of the draft Public Health Officers Bill of the British Medical Association were considered, and it was resolved to take steps to oppose in Parliament any Bill differentiating between part-time and whole-time medical officers of health in respect of condition of tenure. It was decided to issue a memorandum stating the position of affairs at the present time and defining the policy of the Association of Medical Officers of Health.

THE ADMINISTRATION OF POOR-LAW OUT-RELIEF.—A special meeting of the Bangor and Beaumaris board of guardians was held on May 27th to discuss the recently-issued circular of the Local Government Board on the administration of out-relief. Mr. H. R. Williams, one of the Poor-law inspectors of the central Board, pointed out that although every overseer was bound to make a record of the name of every person applying to him for urgent relief and to investigate the case fully, it was necessary to use considerable tact in doing so. He further expressed the opinion that a sufficiency of relieving officers was the truest economy in the long run, and that in every parish where an additional officer had been appointed the man had saved his salary, and not by screwing down the deserving poor but by getting rid of malingerers. A lady member of the board said that the investigations made by the local Charity Organisation Society were very exhaustive, and she considered it was the want of thoroughness of investigation into cases of application for relief that accounted for the weakness of administration of the Poor-law.

CITY OF LONDON MENTAL HOSPITAL: NURSES' HOME.—The Lord Mayor of London, accompanied by the Lady Mayoress, visited Dartford on May 28th for the purpose of formally opening a home which has been constructed for the accommodation of the nurses at this hospital. The building, which was erected by Messrs. Sheffield Brothers, is of Gothic design in accord with the main hospital buildings, contains a recreation-room 27 feet by 18 feet, a reading-room 23 feet by 12 feet, rooms for the assistant matron, and 38 bedrooms for nurses. The size of the bedrooms varies from 120 to 150 square feet. Five bath-rooms and ample lavatory accommodation are provided. The furniture was partly supplied by the firms of Maple and Co. and Davies and Sons, but was partly made in the asylum, the cost being thus kept down, while the electric light and other fittings were put in by the artisan staff of the hospital at a cost of £430. Sir George Wyatt Truscott, chairman of the visiting committee, in asking the Lord Mayor to open the home, stated that in institutions such as the City of London Mental Hospital the efforts of the most expert medical men were of little avail in either ameliorating the condition or promoting the recovery of the patients, unless seconded by skilful and sympathetic nursing. The committee had always been fortunate enough to obtain capable nurses, and many of their nurses had from time to time been selected for responsible appointments in various asylums throughout the kingdom. It was with a view not only to maintain but, if possible, to improve this high standard of efficiency that the home, which the committee asked the Lord Mayor to open that day, had been provided. He asked the Lady Mayoress to accept from the members of the committee a silver photograph frame containing a photograph of the senior nurses and suitably inscribed, while

he presented the Lord Mayor with a signet ring, embodied in which was a gold key which opened the padlock on the door of the home. The ring and padlock were presented by the members of the committee to the Lord Mayor as a mark of their esteem and regard. The Lord Mayor and Lady Mayoress having replied suitably, the home was formally declared open. Among those present were Alderman Sir Thomas B. Crosby, M.D., Sir James Crichton-Browne, M.D., Dr. David Nicolson, C.B., Sir James Moody, M.D., Dr. Sidney Coupland, Dr. Hubert C. Bond, Dr. R. H. Steen (the medical superintendent), Dr. A. E. Patterson, and Dr. N. Navarra.

RESEARCH DEFENCE SOCIETY.—The annual general meeting of this society will be held to-day (Friday, June 3rd), at 5 o'clock, in the Library of the Royal College of Physicians of London, Pall Mall East, S.W., as has been already announced. The chair will be taken by Lord Cromer, President of the society. The other speakers will be Sir Richard Douglas Powell, Sir David Bruce, Mr. Anthony Hope Hawkins, and Mrs. Scharlieb, M.D. All communications on the business of the society should be made to Mr. Stephen Paget at 21, Ladbroke-square, W.

A MUNIFICENT TESTATOR.—Turin has lost one of its best citizens in the notary Giovanni Battista Rejneri, provincial councillor of the district of Carru, whose public spirit and exemplary character earned for him the rank of commendatore. His entire fortune of 700,000 francs (£28,000) he has just bequeathed to the Ottolengo Hospital in Turin, an institution of which he had for many years been administrator, it being one, indeed, of not a few charities which he had supported. His wife, Madame Rejneri, who predeceased him, had also made a considerable bequest (100,000 francs or £4000) to the Ottolengo Hospital.

ASYLUM WORKERS' ASSOCIATION.—The annual meeting of this association was held at 11, Chandos-street, W., last week. The chair was taken by the President, Sir William Collins, M.P. The annual report having been presented by Dr. G. E. Shuttleworth, the honorary secretary, the chairman moved its adoption. In the course of his address he congratulated the association on an increase of 1000 in their membership since last year and on a credit balance of over £150. He added that there was still much to be done to improve the status of asylum workers in the nursing world. The report was unanimously adopted and Sir William Collins was re-elected president of the association.

BIRMINGHAM MEDICAL BENEVOLENT SOCIETY.—The annual meeting of this society was held on May 27th at the Medical Institute, Birmingham. The chair was taken by Sir Thomas Chavasse. The directors, in their eighty-eighth annual report, stated that the invested funds now amounted to £16,090, which, together with a bank balance of £17, made a total of £16,107. Twenty-five annuitants received grants, ranging from £36 to £18, from the society during the year. A donation of £15 was given to a member in need of assistance. The total expenditure in grants and donations was £734. During the year it was decided to admit lady practitioners to the benefits of the society. The directors called attention to the large number of practitioners in the Birmingham district who have not yet joined the society, and urged that a special effort should be made to induce them to join.

DEATH OF DR. ALEXANDER PAULL FIDDIAN.—Profound regret is felt by the whole of the medical profession in Cardiff and the adjoining districts through the great loss which they have sustained in the death from pneumonia on May 23rd of Dr. A. P. Fiddian. The son of a Wesleyan minister, Alexander Paull Fiddian was born in Loughborough, Leicestershire, in the year 1845. He received his early education at Woodhouse Grove School and later entered as a medical student at King's College, London. In 1867 he qualified as M.R.C.S. Eng. and L.S.A. Lond., and in the following year graduated as M.B. Lond. For two years he was resident medical officer at the Cardiff Infirmary, and in 1870 he began to practise in Cardiff. For many years he acted as treasurer of the Cardiff Medical Society, of which he was one of the presidents. He was much interested in temperance work, and was a keen educationist. He had a particularly gentle, courteous demeanour, which endeared him not only to his professional brethren, but to all those with whom he came in contact. He leaves to mourn him a widow, one daughter, and four sons. Two of his sons are in the medical profession, and one was in partnership with his father in Cardiff.

Mr. Robert Barklie, the city analyst of Belfast, died on May 27th.

THE SLEEPING SICKNESS BUREAU. — The managing committee of the Sleeping Sickness Bureau has received from the Agent-General for the Transvaal the sum of £500 as a contribution to the funds of the bureau made by the Transvaal Government on behalf of the four South African colonies.

WE are informed that Dr. James Johnston has resigned his appointment as chief medical officer in London for the Standard Life Assurance Company. Dr. Johnston has been professionally associated with the company for nearly 42 years, for 18 of which he acted as medical adviser in China.

KING EDWARD VII. SANATORIUM.—The third annual report of this institution has just been issued. It is announced that Sir Richard Douglas Powell, Bart., K.C.V.O., having resigned the chairmanship of the staff, Dr. Theodore Williams, M.V.O., has been elected in his place, while Dr. Bertrand Dawson takes the place of Dr. Williams as honorary secretary.

PARENTS' NATIONAL EDUCATIONAL UNION.—The fourteenth annual conference of the Parents' National Educational Union will be held at University College on July 11th to 14th. Amongst the numerous lectures one to be delivered is by Dr. G. H. Savage, entitled, "Nervous Stability: a Healthy Body well controlled is necessary for the making of a Good Citizen."

THE ROYAL SANITARY INSTITUTE.—A meeting of this institute will be held on Wednesday next, June 8th, at 7.30 P.M., at 90, Buckingham Palace-road, S.W., in order to stimulate interest in the Territorial Army movement. An address will be given on the Sanitary Service of the Territorial Force, by Lieutenant-Colonel C. H. Melville, R.A.M.C., professor of hygiene, Royal Army Medical College. General Sir Harry N. D. Prendergast, V.C., G.C.B., will take the chair.

METROPOLITAN HOSPITAL SUNDAY FUND.—A special meeting of the Council of this Fund was held on May 27th at the Mansion House, under the presidency of the Lord Mayor. Resolutions of sympathy with the King and the Queen-Mother for the loss which they have sustained by the death of his late Majesty King Edward VII., who was patron of the Fund, were adopted. In the resolution to be sent to the King reference was made to the visit of his late Majesty to St. Paul's Cathedral in 1903, when the collections for the Fund in places of worship reached a record total. Archdeacon Sinclair, who proposed the resolutions, referred to the constant visits of King George and Queen Mary to the homes of the poor and to all places where the afflicted were given succour. Everyone concerned with charitable work, he said, would always remember how much of what was kind and true in such work had been inspired by the advice and example of Queen Alexandra.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND AND WALES.—The annual meeting of this association will take place at 3 P.M. on Friday, July 1st, in the council chamber of the town hall of the city of Halifax. The President, Surgeon-General G. J. H. Evatt, C.B., will be supported in the chair by the Mayor of Halifax (Alderman F. Whitley Thomson), who with the Mayoress will hold a reception in the Mayor's parlour after the meeting. Papers will be read: (1) Poor-law Medical Reform, What it Should Aim at, by Dr. Major Greenwood; and (2) The Medical Profession and Poor-law Reform, by Dr. J. C. McVail, and upon these discussions will be held. At 7 P.M., the members and their guests will dine together at the White Swan Hotel, Halifax, when the President will take the chair. Tickets, exclusive of wine, will be 6*s*, and ladies will be welcome at the dinner. Any medical practitioner desiring to be present at the dinner is requested to communicate with the honorary secretary, Dr. Major Greenwood, care of Dr. Arthur Drury, Landon House, Halifax.

LONG.—On May 28th, at St. Giles-street, Norwich, the wife of Sydney H. Long, M.D., of a daughter.

MCRAE.—On May 25th, at Glengall House, Ayr, the wife of G. Douglas McRae, M.D., F.R.C.P.E., of a daughter.

MARRIAGES.

COUPLAND—HENDERSON.—At St. Andrew's Church, Drumsheugh-gardens, Edinburgh, on June 1st, by the Rev. W. M. Macgregor, D.D., and the Rev. Alexander Martin, D.D., James Alane Coupland, M.B., B.S. Lond., F.R.C.S., 37, Park-square, Leeds, to Mima Alice, younger daughter of the late James Thomson Henderson, Leghorn, Italy, and of the late Mrs. Henderson, 15, Blantyre-terrace, Edinburgh.

DEATHS.

BLAKE.—On May 20th, in Dublin, Henry Edgar Valentine Blake, of Renvyle, L.R.C.P. & S.

BUCKLEY.—On May 30th, at Broadhurst, Bury Old-road, Manchester, Samuel Buckley, M.D., F.R.C.S., M.R.C.P., in his 64th year.

RICE.—On May 24th, at Southam, Warwickshire, David Rice, M.R.C.S., L.R.C.P. Lond., aged 73 years.

RIX.—On May 24th, at Tunbridge Wells, William Howells Rix, M.R.C.S. Eng., in his 74th year.

ROSE.—On May 29th, in London, William Rose, M.B., B.S., F.R.C.S., in his 63rd year.

SMITH.—On May 28th, at Hallgarth House, Durham, Robert Smith, M.D., in his 78th year.

TERRY.—On May 22nd, at Fox Hill-grove, Bath, Charles Terry, M.R.C.S., L.S.A., aged 85 years.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

NATIONAL CHILDREN'S HOME AND ORPHANAGE.

A SANATORIUM for children threatened with consumption has recently been built at Harpenden by the committee of the National Children's Home and Orphanage. The sanatorium, which is to be opened on Wednesday, June 8th, at 3.30 P.M., by Lady Wernher, stands 430 feet above sea level; it is pleasantly situated and commands a fine view of the surrounding country. There is accommodation for 50 inmates besides officers. The building faces almost due south, and in its centre is a large dining-room with a fine seven-sided bay window opening on to a wide verandah. Adjoining the dining-room are the nurses' sitting-rooms, the wards, each of which accommodates eight patients, and nurses' bedrooms, these having inspection windows commanding a complete view of the wards; there are also two single wards, a waiting-room, and a surgery. At the rear of these apartments is a wide and well-lighted corridor, with bay windows, fitted with French casements, opening on to the grounds. Beyond the corridor and separated from it by a well-ventilated lobby are the large and commodious kitchens, scullery, stores, &c. Below this is the hot-water apparatus for supplying hot water for the baths and for heating the building. A dinner lift is provided near the kitchen for conveying food to the patients on the first floor who are unable to take their meals in the dining-room. The bathrooms, cloakrooms, and lavatories are at the extreme ends of the corridor. The first floor is reached by two well-lighted staircases. Here there are three large wards containing eight beds each, one double ward, and two single wards for severe cases, together with nurses' bedrooms. All the wards have French casements sufficiently wide for the passage of beds to the balcony, at the end of which is an outside teak staircase arranged for use in an emergency. At the rear of the corridor are placed the bedrooms for the staff. At the ends of the corridor the bathrooms, lavatories, and linen cupboards are arranged. Externally the sanatorium is designed in a simple manner. The walls are built of red bricks, and the roofs are covered with brown tiles. Surmounting the centre gable is a quaintly designed bell turret, which is a landmark for the surrounding country and is in harmony with the rest of the building. Open-air shelters have been erected in various parts of the grounds for the use of the inmates. At the back of the sanatorium and some 60 feet away from it a laundry is in course of erection, while a gardener's cottage will be placed at the entrance gates and will serve as porter's lodge.

PREMATURE SYNOSTOSIS.

To the Editor of THE LANCET.

SIR,—I have met with a child, 6 months old, whose anterior fontanelle is closed and who was born with it so. The child is apparently normal in every other way, although during a recent attack of malaria cerebral symptoms were very marked. I can find no reference to this condition in the literature available and have never heard of a similar case. Could you or any of your readers inform me whether any future mental condition is to be anticipated owing to this abnormality, which one is taught is to provide room for the expansion of the growing brain? I am, Sir, yours faithfully,

F. C. MCCOMBIE, M.B. Lond.

Bishnauth, Assam, April 14th, 1910.

*** Microcephalus is nearly always associated with premature synostosis of one or other of the sutures. Sometimes all the sutures are involved, sometimes only one or more. If the frontal alone is involved operation holds out a good chance of conferring some benefit. If all the sutures are involved there is no likelihood of any benefit from operation, and maldevelopment of the brain is always present. If the sutures at the base but not those at the vertex are involved, practically the same holds good. The synostosis and the maldevelopment of the brain progress *pari passu*, and the latter does not depend upon the former. The outlook in the case referred to would appear to be poor. Further information as to the condition of the other sutures and of the size of the head is really necessary before a correct opinion can be formed.—ED. L.

FOOLISH AND DANGEROUS PRACTICAL JOKES.

Two recent prosecutions in London police courts have fortunately had as their result adverse consequences for the vendors of articles adapted for use in the perpetration of "practical jokes" of a disagreeable character, and likely to be associated with pain as well as an appreciable amount of danger to the object of the jester's attack. In the one case the article was a pistol, which has before figured in the courts, and which was then held to come within the provisions of the Pistols Act, 1903, although it was not intended to be loaded with shot or with any other projectile of the usual character. The cartridges destined for it contained, as well as gunpowder, lycopodium and pepper, and it was stated that the discharge of this in a person's face

would not only incommode and alarm him, but might render him for a short time unconscious. In order to avoid the effect of the decision that this weapon was a pistol, and because stress had been laid on the possibility of using it to discharge a bullet, it had been manufactured in a new form with pieces of wire fixed across the inside of the barrel, and it was contended that this rendered its use with shot or bullet impossible. Evidence was, however, given by Mr. Churchill, a gunsmith, that in spite of the wires small shot might easily be fired with very dangerous effect. We are glad to see that Mr. Marsham, sitting at Bow-street, had no doubt that the weapon described was a pistol within the meaning of the Act, and expressed the determination to stop, if he could, the sale of it. The defendant was fined by him the sum of £5 5*s*., with £10 10*s*. costs, and it is to be hoped that no more will be heard of this most undesirable toy. It was, we believe, originally suggested that it would have its uses for the purpose of self-defence, but it was too likely to be employed mischievously by irresponsible and foolish persons for its sale to be permitted if this was preventable. In the other case referred to the prosecution was under the Sale of Food and Drugs Act, 1875, for selling chocolate drops which were "not of the nature, substance, and quality of the article demanded," the fact being that the sweetmeats in question, which were described as "The Catch of the Season Chocolates," contained a liquid prepared from capsicums. The danger and distress which might be caused by such articles coming into the possession of children, if we leave adults out of consideration, need no explanation, and Mr. Denman, who heard the case at the Marlborough-street police court, inflicted a fine of £1, with £3 3*s*. costs. If Mr. Pickwick rather envied the ease with which Mr. Magnus's friends were entertained, it is not recorded that he desired their acquaintance or wished to share with them the privilege of intimacy with Mr. Magnus. Nor would any sensible person seek the society of one who would play practical jokes with pepper cartridges or chocolates charged with capsicum.

AN ARTIFICIAL NAIL.

To the Editor of THE LANCET.

SIR,—In reply to "Medicus Edin.," I would like to strongly recommend Mr. Hy. Brook, 34, Illingworth-road, Bradshaw, Halifax. Mr. Brook has made several excellent artificial noses for patients of mine, and I know he has been equally successful with artificial fingers.

I am, Sir, yours faithfully,

Manchester, May 31st, 1910. LOUIS SAVATARD.

To the Editor of THE LANCET.

SIR,—In reply to your correspondent in this week's issue of THE LANCET, "Medicus Edin.," we beg to state that we have made artificial nails or tips of fingers from time to time. If your correspondent will write to us direct we shall be happy to give him full particulars.

Yours faithfully,

For ALLEN & HANBURYS, LTD.,
HENRY LEWIS, Manager.

48, Wigmore-street, Cavendish-square, London, W.,
May 28th, 1910.

REGULATIONS FOR CHINESE LABOURERS IN SAMOA.

A RECENT order by the German Governor of Samoa makes certain sanitary regulations for the Chinese contract labourers. Their houses are to be well built and airy, whitewashed every quarter, and washed out weekly. They must have suitable fittings for drinking, washing, bathing, and cooking; also a 6½ feet deep, and covered, latrine on the lee side of the house. Each workman must have a sleeping-place, either a bed or a bench, and a mosquito net is to be given him at his own expense. He is to have daily (about) 1¼ pounds of rice, or 1½ pounds of biscuit or pulses, and of meat or fish 4 ounces dried, or 5½ ounces raw or 6 ounces salted, also 1½ ounces pork fat daily, and either green vegetables or opportunity to grow them. The monthly allowance of tea is 5½ ounces, and half the rice may be replaced by yams, bread-fruit, or bananas. The principal medical officer supervises the execution of this order, making an inspection at least every three months.

Sufferer has omitted to entrust us with his name and address.

METEOROLOGICAL READINGS.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

TUESDAY.

SURGICAL SECTION (Hon. Secretaries—Walter G. Spencer, Jonathan Hutchinson), in the Large Theatre, Medical School, University College, W.C.: at 5.30 P.M.

Discussion:

On the Present Position of the Treatment of Syphilis. (To be continued at the next meeting on June 14th.) The Discussion will be opened by Mr. Ernest Lane, and continued by Sir Jonathan Hutchinson, Dr. Alexander Fleming, Mr. Arthur Shillitoe, Mr. H. W. Bayly, Mr. J. E. R. McDonagh, Dr. F. J. Smith, Mr. G. F. Marshall, Dr. G. Pernet, Mr. Charles Gibbs, and Captain Rennie.

WEDNESDAY.

SPECIAL MEETING OF FELLOWS OF THE SOCIETY at Morley Hall, George-street, Hanover-square, W.: at 5 P.M.

Discussion:

On Vaccine Therapy, its Administration, Value, and Limitations (Fourth Meeting). Re-opened by Dr. Arthur Latham, and continued by Mr. Maynard Smith, Dr. Alexander Fleming, Dr. T. J. Horder, Dr. Carmalt-Jones, and Dr. Rufenacht Walters.

THURSDAY.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION (Hon. Secretaries—William J. Gow, G. F. Blacker): at 7.45 P.M.

Specimens:

Dr. Drummond Maxwell: Cystic Degeneration of Mole in Fallopian Tube.

Dr. Inglis Parsons: (1) Fibroma of Fallopian Tube; (2) Fibrotic Uterus causing Persistent Menorrhagia.

Paper:

Sir William Japp Sinclair: The Prophylaxis and Treatment of the Slighter Ailments Resulting from Puerperal Sepsis.

FRIDAY.

CLINICAL SECTION (Hon. Secretaries: H. D. Rolleston, Albert Carless): at 8 P.M.

Annual General Meeting.—Election of Officers and Council.

Cases:

Dr. R. G. Hebb: Lymphadenoma.

Mr. R. C. Elmslie: (1) Three Cases of Schlatter's Disease: (2) Fracture of the Humerus at the Site of an Innocent Cyst.

Dr. H. D. Rolleston: Jaundice with Areas of Unpigmented Skin.

Dr. Poynton and Mr. Wilfred Trotter: Cardiolysis.

Mr. L. Vernon Cargill: Acromegaly with Tumour of the Pituitary Body.

Mr. Lockhart Mummery: (?) Hyperplastic Tuberculosis of the Pelvic Colon.

Mr. Cyril Nitch: Congenital Hairy Mole.

Dr. Wilfred Harris: Trigeminal Neuralgia Treated by Alcohol Injections.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM, 11, Chandos-street, Cavendish-square, W.

THURSDAY.—8 P.M., Card Exhibits by Mr. C. Blair, Mr. R. W. Doyne, Mr. A. H. Thompson, and others. 8.30 P.M., Mr. E. Clarke: Advanced Optic Atrophy following the Use of Soamin and Orsudan for the Treatment of Syphilis in Two Patients.—Mr. N. B. Harman: Cataract Pedigrees.—Mr. R. W. Doyne: Further Notes on Family Choroiditis, with Three Illustrative Cases.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. J. Galloway: Clinique (Skin). 5.15 P.M., Lecture:—Dr. G. E. Herman: Post-partum Hæmorrhage.

TUESDAY.—4 P.M., Dr. G. Rankin: Clinique (Medical). 5.15 P.M. Lecture—Dr. J. Taylor: Some Points in the Treatment of Nervous Diseases.

WEDNESDAY.—4 P.M., Mr. C. H. Leaf: Clinique (Surgical). 5.15 P.M. Lecture:—Dr. A. E. Giles: Pregnancy after Abdominal Operations.

THURSDAY.—4 P.M., Dr. F. J. Poynton: Clinique (Medical). 5.15 P.M., Lecture:—Mr. M. P. M. Collier: On Deformities of the Face and Upper and Lower Jaws, due to Nasal Obstruction.

FRIDAY.—4 P.M., Mr. E. Clarke: Clinique (Eye).

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. Howell Evans), 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. W. Carson). 4.30 P.M., Medical In-patient (Dr. A. J. Whiting).

TUESDAY.—Clinic: 10 A.M., Medical Out-patient (Dr. A. G Auld). 2.30 P.M., Operations. Clinics:—Surgical (Mr. W. Edmunds); Gynæcological (Dr. A. E. Giles). 4.30 P.M., Demonstration:—Mr. H. Evans: Selected Surgical Cases.

WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Dr. A. H. Pirie).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel).

FRIDAY.—10 A.M., Clinic:—Surgical Out-patient (Mr. Howell Evans). 2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie). 4.30 P.M., Lecture:—Mr. R. P. Brooks: The Surgical Treatment of High Myopia.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M. Surgical and Medical. 12 noon, Skin. 2.15 P.M., Special Lecture:—Prof. Hewlett: Prophylactic Vaccination.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 4 P.M., Special Lecture:—Mr. Pendlebury: Surgical Treatment of Empyema and Hydrocephalus in Children.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4 P.M., Lecture:—Dr. Perkins: Angina Pectoris.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY AND FRIDAY.—3.45 P.M., Lecture:—Mr. W. Stuart-Low: Accessory Sinuses.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Mr. P. Sargent: Nerve Anastomosis.

WEDNESDAY.—5 P.M., Demonstration:—Mr. P. Sargent: Surgery of the Nervous System—Infective Diseases.

FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. A. Turner: Treatment of Epilepsy. 5 P.M., Demonstration:—Mr. P. Sargent: Surgery of the Nervous System - Intracranial Tumours.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C. (in the Lecture Room of the Institute).

WEDNESDAY.—6 P.M., Brevet Lieut.-Colonel Sir W. B. Leishman: Anti-Typhoid Inoculation. (Harben Lecture.)

MANCHESTER ROYAL INFIRMARY.

TUESDAY AND FRIDAY.—4.30-5.30 P.M., Honorary Staff: Post-Graduate Clinical Demonstration (Medical, Surgical, and Special Departments).

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (6th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.),

TUESDAY (7th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

WEDNESDAY (8th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (9th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (10th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (11th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Communications, Letters, &c., have been received from—

Three Clinical Lectures

Delivered at the Middlesex Hospital

BY SIR HENRY MORRIS, M.A., M.B. LOND., F.R.C.S. ENG.,

EMERITUS LECTURER ON SURGERY IN THE MEDICAL SCHOOL.

LECTURE III.[1]

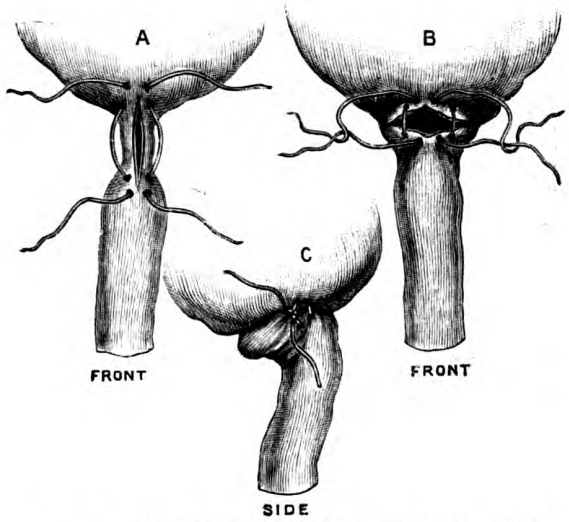
Delivered on March 8th.

ON THE OPERATIVE TREATMENT FOR PREVENTING THE DESTRUCTIVE RENAL CHANGES IN HYDRONEPHROSIS AND PYONEPHROSIS.

GENTLEMEN,—I will first enumerate and classify the various causes of hydronephrosis and pyonephrosis, and briefly describe the symptoms caused by both the open and closed distension sacs, or, in other words, by intermittent and persistent retention of urine or urine with pus in the renal pelvis and calyces, and I will then proceed to illustrate the proper treatment for preventing the more advanced and destructive changes which affect the kidney in these diseases by narrating a few cases which have been recently under my care.

[I will here omit these introductory remarks and pass at once to an account of the cases and the lessons taught by them.]

I. HYDRONEPHROSIS.



The patient, a female domestic servant, aged 30 years, was an in-patient at the Middlesex Hospital in 1898 from July 1st to July 6th and again from Sept. 23rd to Oct. 14th, and gave the following history of herself.

For 12 years she had suffered a sharp tearing pain in the right side of her abdomen and right loin, sometimes shooting downwards to the right groin. These attacks had recurred at intervals of about one month, usually lasted 24 hours, and were accompanied by vomiting. They quite incapacitated her and compelled her to keep in bed. For the last year or so they had been more frequent and more severe, and just prior to her admission into the hospital in July she had had three attacks in seven weeks, though for eight weeks preceding her readmission in September she had been entirely free of any attack. Any great exertion, such as hard work or violent exercise, frequently brought on an attack, and rest in bed gave relief. She thought she passed less urine during a period of pain and just before, and at these times there had frequently been blood in it. The urine was often very thick just after a severe attack. There had never been any pain or undue frequency in micturating. During the times she was under observation in the hospital the quantity of urine passed in 24 hours varied from 20 to 50 or 55 ounces, and the specific gravity of it from 1004 to 1022.

A daily examination of the urine was made for three consecutive weeks in September and October, 1898, without detecting in it either blood, pus, or albumin; yet on other occasions a few leucocytes, a trace of albumin, a little excess of mucus, a few epithelial cells, and one or two granular casts were observed. No enlargement of either kidney could be detected, but at no time whilst she was in hospital had we the opportunity of examining her in one of her attacks; and only on two or three occasions did she complain of slight aching or an "uncomfortable sensation" in one or other loin and hypochondrium. There was, however, slight tenderness on palpation of the right loin and right side of the abdomen as far forward as the right semilunar line; there was also more resistance to pressure on this side than on the left. As she was free from pain and there seemed no distinct indication for operative treatment she was made an out-patient under one of the assistant physicians. In less than a month, however, she was again re-admitted. She then stated that 14 days after leaving the hospital she had a severe attack of pain in the right side of the abdomen, and that a dull, aching pain in the right loin, which completely disabled her from following her occupation, had continued ever since. A sample of her urine which she brought with her contained blood. Renal calculus was suspected as the probable cause of the symptoms, but the alternative diagnosis of intermittent hydronephrosis was not lost sight of. An exploratory operation on the right kidney was decided upon and was carried out on Nov. 7th, 1898. The kidney was brought on to the surface of the loin and thoroughly searched for a calculus, a digital examination of the interior through an incision along the convex border of the kidney having been made for the purpose. No stone being found, the renal pelvis, which was ballooned to the size of an orange, was incised, and the finger, introduced through the opening, made a further examination of the interior of the organ. A bougie was next passed along the ureter into the bladder in search of a stone in the ureter. The calyces of the kidney were found to be dilated, and the upper end of the ureter close to the renal pelvis was constricted and sclerosed, so that the bougie passed with resistance through it.

The cause of the hydronephrosis was thus evident, and therefore, instead of excising the kidney, the wound along its convex border was sutured, the strictured part of the ureter was divided by a longitudinal incision and sutured in the manner shown in the woodcut (Fig. 1), and the incision

FIG. 1.

From Morris's book, Surgery of the Kidney and Ureter. (Kindly lent by Messrs. Cassell and Co.)

in the renal pelvis was closed by sutures. The parietal wound was sutured with six deep and six superficial silk stitches, and the bladder was sounded to be sure that no calculus had slipped into it from the ureter during the operative procedures.

During the first 24 hours after the operation some blood was passed with the urine. A drain-tube reaching to the kidney was removed from the lumbar wound on the second day. No urine escaped at any time from the lumbar wound. The patient made an excellent recovery, and was really well on the eighteenth day; she was, however, detained in the hospital until Dec. 21st, 1898, in case of any subsequent complication occurring.

On June 6th, 1899, that is seven months after the operation, the patient came to the ward to report herself, when she told us that she had been in excellent health, and had had no pain or trouble of any kind since leaving the hospital. At this time the lower end of the right kidney could be felt below the edge of the rib; there was no tenderness on pressure, and no enlargement; the kidney seemed well fixed in position.

Nothing more was heard of this patient for nearly 10½ years; but on Nov. 19th, 1909, I received a note from Mr. Kellock telling me that the patient had been admitted to hospital under his care on account of some pain and tenderness on the right side of the abdomen, and adding that she did not seem at all ill, that he did not think anything surgical was required to be done, and that the urine

[1] Lectures I. and II. were published in THE LANCET of May 28th (p. 1455) and June 4th (p. 1517), 1910, respectively.

was normal except for a few leucocytes and a slight trace of albumin.

I took the opportunity, so kindly given to me by Mr. Kellock, to visit the patient. I ascertained that she had enjoyed good health during the 11 years since the operation until a week before her admission into the hospital ward, when she had an attack of pain in the abdomen with a temperature of 102° F. lasting two days. Nothing further followed. Nothing abnormal was revealed by the X rays, and after a stay of 10 days in the hospital she was discharged.

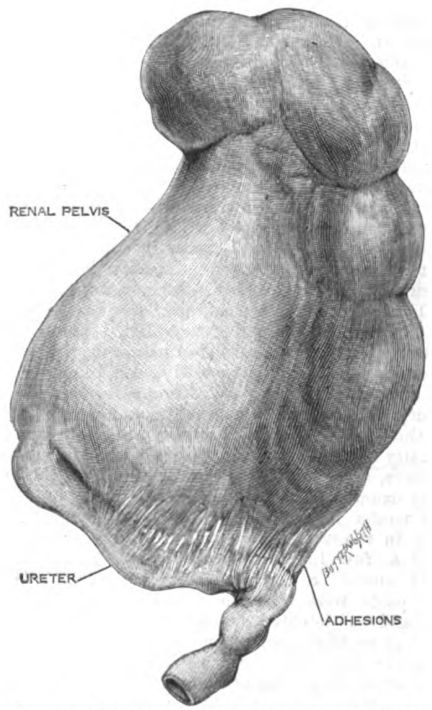
Remarks.—This case affords us the opportunity of judging of the lasting benefit of the operation after an interval of 11 years, and for this reason I have related it to you.

It chanced, when looking over the volume of hospital cases in which the notes of this patient were bound up, that I came across those of an almost parallel case which also was under my care in April and May of 1898. It was that of a married woman, aged 30, who had suffered several attacks of intense pain, with vomiting, coming on suddenly and associated with a certain amount of hæmaturia. Since the first attack the urine had sometimes been chocolate-coloured and very offensive. The attacks had come on under different circumstances. One commenced just as she had stepped down from an omnibus; another just as she was rising from the recumbent position after sleeping. Sometimes with the onset of pain she had had shivering, followed by sweating and a sense of burning heat. Sometimes she had been violently sick. The attacks varied in duration from 12 hours to 2 days. There had been no indication, so far as was known, of any renal distension.

In this case also the renal colic and other symptoms suggested renal calculus; but in any case it was only by an operation that the cause, if not a calculus, could be ascertained. I thought that in great probability the abnormal condition would be one which could be removed by surgical means. Search was made in this case by an exploratory operation exactly as in the first. No stone was present, but the kidney was moveable and markedly hydronephrotic. The cause of the obstruction was a valve attached to the posterior half of the wall of the ureter just below the renal pelvis. A bougie could not be passed from above downwards along the posterior wall of the ureter, but easily upwards from an opening in the ureter below the valve. This obstruction was removed by an operation precisely like that performed in the first case and as shown in Fig. 1.

Recovery was rapid and complete. In response to a letter of inquiry, this patient also came to the hospital on June 6th, 1899. Except for an attack of influenza at Christmas she had been quite well ever since the operation; her urine was tested and found to be quite normal.

Remarks.—These cases afford complete proof of the value of uretero-plastic operations as a means of securing absolute immunity from the severe attacks of pain and other symptoms caused by hydronephrosis; and of putting a stop to the further disorganising effects of ureteral obstruction on the structure and function of the kidney, whether the obstruction is due to valve, stricture, or other such-like condition.



I have successfully operated in precisely the same way in several cases, and in one only has it been necessary to remove at any subsequent period the kidney so treated. In that case the renal pelvis was the size of a cricket-ball, and the operation was followed by entire disappearance of all symptoms. Twelve months later she was delivered of a fine child at full time, and subsequently she continued well for a considerable period. She was of a very active and excitable temperament, and a devotee to riding and hunting. Whether from chill or other cause I am unable to say, but later on, after a second confinement, she had repeated attacks of pyelitis in the same kidney, going over a period of two or three years; and in April, 1906, eight years after the ureteroplasty, I removed the organ, in the renal pelvis of which was a large secondary calculus.

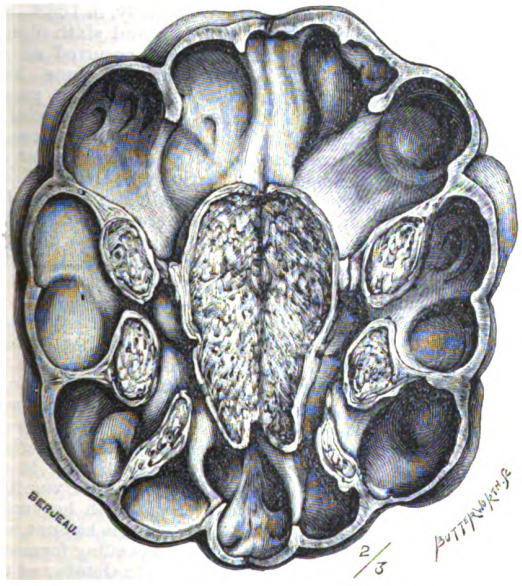
The liability of cases of uncomplicated hydronephrosis being mistaken for renal calculus is very great. If the parenchyma of the kidney, as well as the renal pelvis and calyces, has not become dilated so as to form a large intermittent or permanent abdominal swelling; or even if there is an intermittent tumour, but the practitioner does not happen to see the patient during the dilated stage of the kidney, the diagnosis first made, and probably tenaciously held, will be renal calculus. If the sudden attacks of pain are complicated with vomiting, shivering, and hæmaturia, and more especially if the attacks are induced by violent exertion or sudden movements, they will certainly be regarded as renal colic of calculous origin.

In some cases the hydronephrotic kidney, even in spite of an extreme degree of atrophy of the renal parenchyma, does not attain to a size larger than the normal organ. I have known a kidney of this kind, when the dilated renal pelvis has been in a collapsed state, pass undetected even in the course of an exploratory operation. I recall being present on one occasion when the surgeon, having commenced the operation with the pre-formed conviction he would find a stone, after manipulating the kidney in the depth of the wound, remarked, with a look of surprise and disappointment, that the kidney was soft and not enlarged and did not, he was sure, contain a calculus. He was about to close up the wound in the loin when I ventured to suggest that it would be well to bring the kidney on to the surface of the loin and inspect it. Having done so, the surgeon found the organ in such an advanced stage of hydronephrosis that nephrectomy was clearly indicated and carried out with most successful ultimate result.

Some years ago when the X rays were coming into common use in surgery I did not hesitate to predict that in future many renal affections which could be corrected by operative treatment only would be allowed to drift on unrelieved because, though symptoms pointed to calculus as their cause, the X rays did not yield a shadow in verification of this diagnosis. How true this forecast has been time has amply proved. I could quote a number of cases in confirmation of it, cases in which patients have lingered on in suffering, disinclined to, and often discouraged from, undergoing an operation on the ground that as a calculus could

FIG. 2.

Back view of right kidney, showing dilated renal pelvis and adhesions binding the ureter to it. The ureter is seen to come off from the renal pelvis some way above the lowest point of the pelvis.



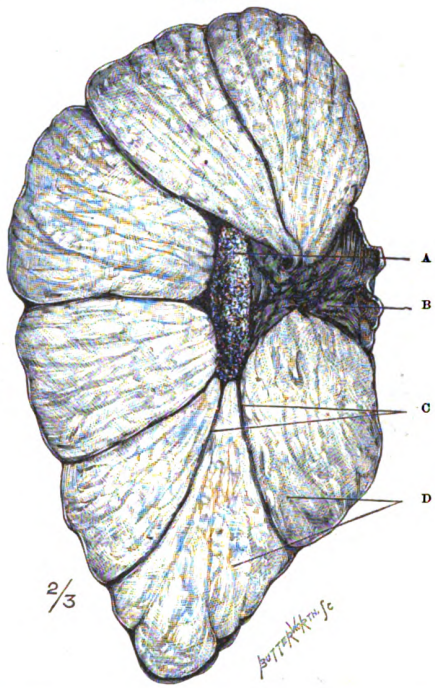
not be discovered by the X rays an operation on the kidney would be useless. Perhaps even worse still, unnecessary operations have been undertaken, in the absence of the shadow of a renal calculus, on some other organ such as the appendix cæci. I have had to perform nephrectomy in two cases within the last ten months for simple hydronephrosis too advanced to allow of any plastic operation being useful, in patients who were supposed to have renal calculus and on whom operation on the kidney was not performed because of the negative results of examination by the X rays. In each case I urged an operation, believing the

cause of the symptoms to be due to intermittent distension from ureteral obstruction.

One of these patients was a Parsee lady from Bombay who came to me accompanied by Mr. P. P. Bhedwar of Blackheath, and who for some years had suffered renal colic on the right side. I operated on June 17th, 1909. The cause of the symptoms was found to be a large hydronephrotic sac due to a sigmoid curve at the upper end of the ureter, which was tied down by areolar tissue bands to the surface of a ballooned renal pelvis in the manner shown in Fig. 2. The operation of pyelo-ureterotomy, or perhaps pyelo-ureterotresis, such as I have described fully in my book on the Surgery of the Kidney and Ureter (Vol. II., pp. 437 and 438; also pp. 533–536), and in my Hunterian lectures (1898, p. 20 *et seq.*), would have completely removed the cause of obstruction and prevented the progress of the destructive changes. (Operation explained and illustrated by diagrams.)

The second case was that of a Roman Catholic priest, aged 32, who was sent to me by Mr. E. D. Agnew of Bishop's Stortford, upon whom I operated in December last. For 11 years he had suffered attacks of right renal colic attributed for years to renal calculus. After repeated skiagrams had been taken with negative results the appendix cæci was accused, and in 1905 removed. On the tenth day after the appendectomy he had the worst attack of pain he had ever experienced, and others recurred with even greater frequency than ever before up to the time when I first saw him in December, 1909. At the operation I found the ureter bound down in a sigmoid manner to the surface of the ballooned renal pelvis; and in this instance the curves were so strongly impressed upon the tube that after the adhesions had been divided and the ureter set free and straightened out it sprang back again into its curved form when left alone; and this it did again and again, showing it would have been useless to have merely divided the adhesions without also doing a plastic operation on the renal pelvis and ureter, and in this case resecting a piece of the ureter also.

FIG. 3.



Sacculated hydronephrosis showing a considerable ingrowth of fat at the hilum. From Morris's book, Surgery of the Kidney and Ureter. (Kindly lent by Messrs. Cassell and Co.)

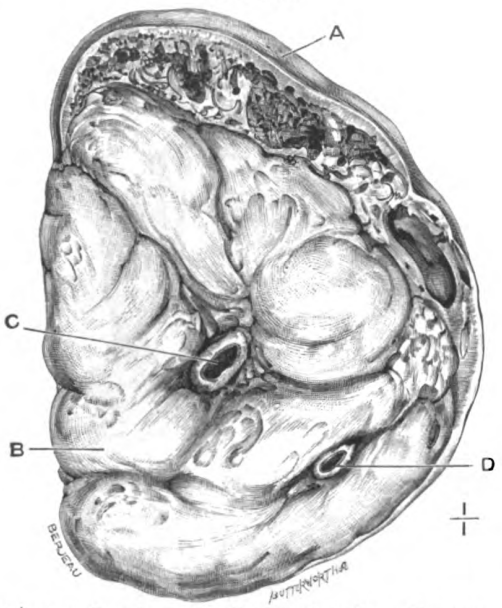
In a third patient who was recently under my care for a renal trouble the appendix cæci had been removed on the supposition that it was the cause of the disorder; but much to her disappointment she experienced a severe attack in the third week after the operation in every respect similar to those she had suffered previously.

In both the cases just related nephrectomy might have been escaped, and the kidney could have been saved by pyelo-ureterotresis, had the operation been performed in proper time.

I am convinced that the profession generally does not realise the importance of recognising the symptoms of hydronephrosis as early as possible. I am sure that attention needs to be drawn to such cases as I have narrated. I am certain that surgeons should bestow a little more thought on what is capable of being done in the earlier stages of simple hydronephrosis, and exercise an equal amount of skill on the plastic surgery of the renal pelvis and ureter to that which they are in the present day devoting to gastric and intestinal affections and the various operations for their relief. If they would do so, the sum of human suffering would soon be reduced by an immeasurable number

FIG. 4.

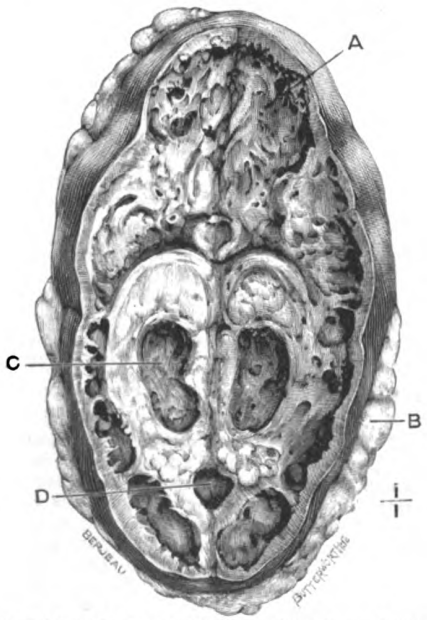
Fatty transformation of the kidney. From Morris's book, Surgical Diseases of the Kidney and Ureter; Dr. Rickards's case, Fig. 118, p. 74, vol. ii. A, Calculus. B, Renal pelvis obliterated by dense, tough cicatricial-like tissue. C, Fibrous septa in which run large blood-vessels. D, True fatty tissue. (Kindly lent by Messrs. Cassell and Co.)



of very distressful years, and hundreds of patients who otherwise are destined to lose the functional activity of one of their kidneys would be spared the pain and risk attending the disorganising process, and would be enabled to retain the affected organ in a very high degree of efficiency, instead of, later on, in accordance with present practice, having to get rid of it as an useless and health-destroying encumbrance.

II. FATTY TRANSFORMATION OF THE KIDNEY.

There are scattered through the standard works on diseases of the kidney, and in the Transactions of the Pathological Society of London, a few instances in which the whole or the major part of the kidney was replaced by fatty or fibro-fatty matter. In some of them this fatty transformation was associated with calculus, and in others with suppurative pyelonephritis. In some instances the contour of the organ has been preserved, and the dimensions not greatly, if at all, increased; in others large irregular tumours have been formed of several pounds in weight, and of the size of the human head or bigger. In some the fatty tissue is an extension inwards from the circumrenal fat, which after filling the hilum spreads throughout along the connective tissue surrounding the larger blood-vessels; thus it compresses and causes atrophy of the tubular structure to the degree of absolutely destroying it, or spreads the atrophied renal substance like a capsule over the tumour.



The commencement of this particular inward growth of fat is seen in Fig. 3. In other cases the conversion is due to a hypertrophy of the fat, which in small amount is normally present between the apices of the renal pyramids, and which as it grows into the interstitial tissue of the organ slowly invades and destroys the renal tissue; but even when the fat has gradually distended the capsule the kidney still preserves its normal general outline.

FIG. 5 A.

Transformation of pyonephrotic kidney into fat. A, Remnant of pyonephrotic kidney not yet transformed into fat. B, Fatty mass of transformed organ. C, D, Sinus tracks left by drainage-tubes. Vertical section through convex border and renal pelvis.

FIG. 5 B.

Transformation of pyonephrotic kidney into fat. A, Remnant of pyonephrotic kidney not yet transformed into fat. B, Fatty mass of transformed organ. C, D, Sinus tracks left by drainage-tubes. Section of the sacculated portion as yet untransformed into fat.

In the case published in 1883 by Dr. Rickards the whole of the left kidney was transformed into true adispose tissue (Fig. 4), and was half as large again as normal. In the case published by Godard the lower half only of the kidney was converted into a mass of ordinary fat, and a large calculus was lodged in the renal pelvis, as in Rickards's case. In another case there were small abscesses found in the fat, and in one of the abscesses a calculus. In a fourth case the transformed kidney was surrounded by a perinephric abscess. In a fifth case there was no renal artery coming from the aorta.

In the case which has recently come under my notice the left kidney had been the seat of suppuration for some years, and had been converted into a large many-chambered pyonephrosis. All but a small part of it had been transformed into a mass of yellow adipose tissue with traces of irregular septa between the large lobules of fat. The only portion which was not thus transformed was in the front and upper section of the organ. Here there was a series of four or five small sacculi, separated by thick tough partitions and occupied by stinking pus or pus and urine. A sinus ran through this portion and also through the adipose mass into which the rest of the organ had been converted, and a second and larger sinus ran through the centre of the fatty mass. Both these sinuses are shown in the Figs. 5 A and B, and were the tracks occupied by two drainage-tubes which had traversed the kidney from a wound on the front of the abdomen to another in the loin. The drain-tubes had been introduced on July 8th, 1909, and the kidney was removed from the patient on Oct. 30th, 1909. As in July the kidney was known to be a large, many-chambered pyonephrotic tumour, we are supplied with definite data as to the maximum period within which this extensive transformation took place, though we cannot state precisely what was the minimum time it actually occupied.

In the third and fourth cases to which I have above referred there were fistulous tracks opening on the surface of the body and discharging pus, as there were in the case under my care.

I will now briefly relate the clinical history of the patient from whom I removed this fattily transformed kidney, because in addition to this interesting and rare change in the organ the case conveys instruction on at least three points connected with the surgical treatment of pyonephrosis.

A lady of miniature stature, now 39 years of age and the mother of four children, 16 years ago—namely, in 1893—met with an accident when between the fifth and sixth months of her second pregnancy. This accident occurred as she was crossing a room by falling between some loose boards in the floor, when her left leg and thigh passed through nearly up to her pelvis. No immediate serious ill consequence followed, and her baby was born in due course at full time. But on getting up after her confinement she complained of pain across her back at the level of her kidneys, and this pain continued to trouble her more or less persistently. Two other pregnancies were followed by the birth of two children at full time—one, her third child, in 1896, and the other, her fourth child, in 1898. In the interval between the third and fourth confinements—that is, between 13 years and 10½ years ago—she became very ill, pus appeared in her urine, and her family medical attendant told her she had a serious affection of her kidney for which she ought to have an operation, and that the sooner it was done the better. Two other medical men in Johannesburg, where she was living at the time, who were called in consultation agreed in this opinion. She, however, declined to consent to any operation in Africa. Throughout the following 8½ years she suffered attacks of pain in the region of the left kidney associated with sudden vomiting and the passage of large quantities of pus with her urine. Rigors attended many of the attacks. Hæmaturia had not been known to occur. In the summer of 1907 a swelling formed in the left side of the abdomen and liver, and in October of this year (1907) she at length consented to undergo an operation. At this time she was in England residing in the country in one of the Home Counties, and there the operation was performed by a local practitioner. It consisted of an incision over the prominent part of the swelling, along the left linea semilunaris; the kidney was incised, search made for a stone, and (as the patient and her friends confidently asserted they had been at the time informed) a portion of the kidney was removed. It would seem that the impression formed at this time was that the kidney was tuberculous. A large drain-tube was introduced and brought out at the abdominal wound. A fistula was established and gave exit to pus, but as the escape was frequently obstructed the fistulous opening was enlarged in February, 1908. Four months later, in June,

1908, an oblique incision 2½ inches long was made extending at nearly a right angle from the fistulous opening, and through this incision a flat and triangular-shaped calculus escaped. No improvement, however, followed, and she subsequently changed her residence to Kew, and called in Dr. G. J. Maguire of Kew Gardens to attend her.

On June 21st, 1909, the day I first saw her, the discharge from the fistula had been continuing for 1 year and 8 months, and the patient was reduced to the extremest state of emaciation and a condition of pallor amounting almost to clear transparency of skin. Rigors, high temperature, vomiting, and diarrhœa were frequent symptoms; and I quite agreed with Dr. Maguire that she had not long to live but that her life would quickly flicker out unless relief could be obtained by further surgical procedure. At the same time the risks of an operation in her very precarious state were by no means slight.

After removal to a nursing home in London I explored the kidney on July 8th, 1909, through an oblique lumbar incision. The kidney was found to be enlarged, pouched, and sacculated, but entire in its contour. Clearly no portion of the organ had ever been excised. It was freely incised, and sacculus after sacculus was laid open by cutting through tough thick septa. A quantity of foul urine and pus was evacuated. The fistulous opening in the front of the abdomen was enlarged and pared, and two large drainage-tubes were passed right through the kidney and made to emerge at both the abdominal and the lumbar wounds. Great improvement in health followed, and at the end of July (31st), as there was but little discharge coming away, an attempt was made to close the anterior opening and to drain the renal cavity by means of one tube introduced through the loin wound only. She returned to her home on August 5th much stronger and better in all respects, and there seemed promise of the discharge ceasing entirely and of the wounds closing. Our hopes were not realised, however, and therefore she came back to the surgical home, and on Oct. 30th, 1909, I performed nephrectomy through the lumbar incision, after excising the twelfth rib. I had expected to find great difficulty in separating the kidney from its bed after so prolonged a period of suppuration within it, but I was agreeably surprised at the easy way in which I was able to enucleate it. And this surprise was by no means diminished when I cut the organ open and found it had undergone the transformation I have already described.

On Nov. 3rd, 1909, the drainage-tube was finally discontinued. It was the first time for two years she had been without a drain-tube for a single day. On the 27th she returned home; in January, 1910, the wounds were quite healed, and now, in March, she is quite well. Those who had witnessed the precariousness of her condition in June, 1909, regarded her recovery as little less than a resurrection.

This case accentuates the teaching which I have frequently enforced before in this theatre and in the wards of our hospital and elsewhere, viz.:—

1. Pyonephrosis should be drained through a *lumbar* incision as soon as ever the diagnosis is established; and even before it is certain, from the evidence afforded by palpation, that the kidney is dilated and sacculated, an incision into it should be made when pyuria, with frequent exacerbations of symptoms, is present. Had the advice of the Johannesburg practitioners been acted upon this patient would have been spared years of ill-health and would probably have had her kidney saved.

2. The absolute necessity in *many-chambered* pyonephrosis to make sure that all the chambers or sacculi are opened into and drained.

3. The folly or worse of attempting to drain a suppurating kidney through an incision in front. Through the loin the route is simple and direct and the exit of the drain or drains is in the most dependent position.

4. When owing to the impossibility of keeping up a satisfactory drainage of all and each of the pouches or sacculi, or when the pyonephrosis is very advanced and old, nephrectomy is the only operation which offers a chance of cure. Had the patient's general condition permitted of it I should have performed nephrectomy in July, 1909, but it was not until after the general improvement which free drainage through the loin secured that the patient was in a fit state to undergo the major operation.

5. The knowledge afforded by this and other cases of the complete disappearance of renal secreting structure after prolonged irritation and suppuration teaches us how useless it is to leave within the body an organ affected with such old-standing disease. In cutting short the illness by nephrectomy we are but anticipating the complete cessation of function of the kidney by the progressive process of transformation into fat or fibrous tissue, which the organ will undergo if not removed.

I have published cases in proof of this statement; notably, a very striking and instructive one recorded in my work on "Diseases of the Kidney and Ureter" (vol. ii., p. 349), in which the kidney, after suppuration following injury, was converted into a small flat triangular fibrous mass and the ureter was in great part obliterated.

Arris and Gale Lecture

ON

THE PHYSIOLOGY OF THE HUMAN LABYRINTH.

Delivered before the Royal College of Surgeons of England on March 18th, 1910,

BY SYDNEY SCOTT, M.S., M.B. LOND., F.R.C.S. ENG.,

ASSISTANT AURAL SURGEON TO ST. BARTHOLOMEW'S HOSPITAL; SURGEON FOR DISEASES OF THE EAR AND THROAT TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

GENERAL ANATOMY AND TOPOGRAPHY OF THE LABYRINTH.

MR. PRESIDENT, LADIES, AND GENTLEMEN,—The labyrinth or internal ear in which the eighth nerve ends is a membranous structure situated in the petrous portion of the temporal bone. The cavity in which the membranous labyrinth lies is called the osseous labyrinth. It is lined by a delicate periosteum. The membranous labyrinth contains a fluid known as endolymph, and is partly surrounded by a fluid called perilymph. The bony labyrinth consists of three main parts—the three semicircular canals, the vestibule, and the cochlea. In the vestibule are the saccule anteriorly and the utricle posteriorly; the latter receives the opening of the three semicircular canals. The saccule communicates with the membranous duct, which is lodged in the bony cochlea. Each semicircular canal is set in a plane at right angles to the others. The external canal is horizontal; the other two are vertical—viz., the anterior or superior, and the posterior or inferior, which is also internal. Contrasting the two labyrinths, the horizontal canals occupy approximately the same plane. In relation to the topography of the head, the superior canal lies in a plane which, according to my measurements, is inclined at an angle of 37° to the coronal plane; the posterior canal is inclined at an angle of 37° to the sagittal plane. The superior canal on one side, therefore, forms an angle of 15° with the posterior canal on the opposite side.

MORPHOLOGICALLY—A DUAL ORGAN.

Evidence shows that the eighth cerebral nerve is composed of two portions; although blended in their course, they differ in their peripheral terminations, central connexions (compare Gordon Holmes), period of medullation, and functions. In some animals, according to Biehl,[1] e.g., the horse, and, more distinctly, the sheep—the two portions, the vestibular and the cochlear, are independent, and can be divided separately.

VESTIBULAR GANGLION.

The vestibular ganglion, first described by Scarpa about 1760, is situated in the internal auditory meatus, and is connected by an upper branch with the utricle and ampulla of the superior and external semi circular canals, and by a lower branch with the saccule and the posterior semicircular canal. Centrally, the fibres from the vestibular ganglion enter the medulla oblongata between the restiform body and the bulbo-spinal root of the fifth cerebral nerve, and are indirectly connected with the cerebellum.

[1] Beitrag zur Lehre von der Bezielung Zwischen Labyrinth und Auge, Arb. a.d. Neurol. Inst. a.d. Wien Univ., Band. xv., Teil 1, 1907.

COCHLEAR GANGLION.

The cochlear ganglion is situated in a spirally arranged space in the modiolus or central axis of the cochlea. Its peripheral fibres are distributed in the organ of Corti, and its central fibres run dorsal to the vestibular nerve towards the restiform body, over which most of them pass, toward the mid-brain, and not the cerebellum. (Cf. Gordon Holmes, Comparative Anatomy of the Nervus Acusticus, Transactions Royal Irish Academy, 1903, p. 140.)

DEVELOPMENT.

W. His, jun., is responsible for the view that the inferior branch of the vestibular nerve belongs to the cochlear nerve, which was physiologically doubtful, and which G. L. Streeter[2] has shown to be incorrect. Dr. John Cameron and Dr. William Milligan[3] have come to similar conclusions, after an embryological study of the otic vesicles and nerve histogenesis in vertebrates.

VESTIBULAR SYSTEM.

The intimate connexion of the vestibular nerve with the cerebellum has been spoken of recently by Dr. Risien Russell in his Lettsomian lectures. "The most important peripheral sense-organ from which the cerebellum receives afferent impressions is the labyrinth, and the path by which they are conducted is the vestibular nerve."[4]

EARLY EXPERIMENTAL RESEARCHES ON CEREBELLUM AND LABYRINTH.

It is not, therefore, irrelevant to very briefly allude to the experimental study of the cerebellum which eventually led to the discovery of certain previously unknown functions of the labyrinth. The earliest experiments on the cerebellum, according to Sherington, appear to have been by du Verney in 1697.[5] Du Verney's name is of particular interest to otologists, for I find he was an aural surgeon as well as an anatomist. His book, translated and published in London after his death, 1727, was the first special treatise on aural diseases in our language.[6] In 1822 came Flourens, whose life forms an era in the history of the labyrinth. It will be remembered that Flourens found that injury to the deep structures of the cerebellum produced marked disturbance of equilibrium. But he went further than others had done, for in 1828 he observed what was certainly at that time an astonishing fact, that precisely similar results were evoked by injury to the semicircular canals alone. It was years before the significance of this epoch-making revelation was properly appreciated. The notion that the internal ear served no other functions than that of audition was so deeply rooted that no one seems to have attempted to repeat these observations until long afterwards. For nearly 20 years Flourens continued his researches in experimental neurology. He found that division of one canal caused rotatory movements of the body, and that the axis of rotation was at right angles to the severed canal. He was led to observe that these motor disturbances, like those produced by injury to the cerebellum, were of the nature of coördination—one set of muscles contracting, while another set relaxed.[7]

FLOURENS'S DATA CONFIRMED.

I can only mention the names of a few of the earlier observers to investigate Flourens's data. In 1869 Löwenberg showed that the phenomena produced by dividing the semicircular canals of pigeons were not due to injury to the cerebellum as some had averred, for he found that the incoördinate movements could be set up by stimulating the ampullary nerve endings in the divided canals.

THE INFLUENCE OF THESE OBSERVATIONS ON MEDICAL OPINION.

It is interesting to try to ascertain how these discoveries first began to affect medical opinion. During the first 30 or 40 years which followed the announcement of Flourens's discovery, we find no reference to his work on the labyrinth in general medical or otological literature, until 1861, when Ménière first introduced the subject. Ménière, therefore, stands out prominently, because he was the first to realise the value of these results in experimental physiology when applied to clinical medicine. Before this time the symptoms, which are often spoken of as Ménière's, were believed to be due to a threatened cerebral apoplexy; and patients manifesting these symptoms were so treated, and treated rather desperately.

CHIEF PERIOD OF PHYSIOLOGICAL INVESTIGATION ON THE LABYRINTH.

There seems no doubt that the relationship which Ménière established between physiology and practical medicine led to and encouraged the more thorough investigations which were carried on after 1870. This period witnessed the master work of Mach and Breuer in Austria, and Cyon, who came from Russia to Paris. In this country important work was done by Crum-Brown in Edinburgh in 1872, and confirmatory observations were made a little later by Dr. Peter McBride[8] in Edinburgh, 1880, and by William James[9] of Harvard in America, 1882. Exhaustive researches of Mach, Breuer, and Cyon extended over several years, and have since been supplemented by many others, including especially J. C. Ewald in Germany, Stanislaus von Stein in Russia, and van Rossem in Holland. To these we must add the names of Lee, who investigated the labyrinth of cartilaginous fish, and of Karl Biehl, who has studied it in the horse and sheep.

CLINICAL PHYSIOLOGY.

Our knowledge of the functions of the labyrinth was advanced by experimental physiologists, and during the 40 years which followed Ménière's prediction hardly any progress can be claimed by clinical physiologists, except for Dr. Hughlings Jackson and one or two other contributors, including Schwabach, who described cases of vertigo and nystagmus associated with ear disease. In 1874 von Tröelstsch said: "The internal ear is completely removed from the direct operations of the physicians and surgeons," and so spoke of it in as few words as possible.

Real advance on the clinical side may be said to date from the stimulus produced by Jansen's paper giving an account of ten cases of operation upon the labyrinth in the human subject. This was in 1898 at the Otological Congress in Moscow. The possibilities awakened by Jansen's pioneer surgery of the labyrinth formed the great incentive to otologists to perfect the methods for diagnosing its diseases. The arduous work of those few who were engaged independently in clinical researches became recognised as of great practical importance and interest. In this country attention to the subject was first directed by Dr. Milligan, Mr. Whitehead, and by Mr. Lake. The way was prepared by Sir William Macewen and Mr. C. A. Ballance, to whom otology owes so much for the application to it of the principles of modern surgery. It was only natural that otologists should refer back to the important researches in experimental physiology carried out between 30 and 40 years ago, and amongst the first to appreciate the practical importance of this combined study of the physiological and clinical problems appear to have been Alexander and Bárány in Vienna. The latter's work especially has become well known to us owing to the papers by Guthrie,[10] Tweedie,[11] Pike,[12] McKenzie,[13] and others. Panse of Dresden (1902) also drew up a detailed guide for investigating the internal ear, which has received less attention in this country than it deserves.

MICROSCOPIC ANATOMY.[14]

In order to understand the mechanism of the labyrinth of which we shall now speak, it is necessary to examine the peripheral distribution of the vestibular nerve. We shall first direct attention to the ampullæ of the semicircular canals, which are the parts peculiarly sensitive to stimulation. As we know, each canal is supplied with a branch of the vestibular nerve. In each ampulla is a transverse crescentic septum, the free margin and surfaces of which are covered with ciliated epithelial cells. In suitable sections cut in paraffin we find one cilium for each cell. The cilium

is partly intra- and partly extra-cellular. The extracellular portion of the cilium is a fine, tapering filament, which in man measures nearly 0·04 millimetre in length (Schäfer gives the length 0·03 millimetre). The two portions of the cilium are in perfect continuity with each other. The intracellular portion is characterised by an ovoid expansion, which makes the total length of the cilium 0·064 millimetre. (I cannot find a similar appearance figured in the works of Gustav Retzius or of other anatomists.) The filaments of the ampullary nerve are traceable to this highly differentiated epithelium, where they end in beaded fibrillary network among the cells. The extracellular portions of the cilia project into the endolymph of the ampulla and are so slender that we can readily conceive how they sway to and fro in the slightest current set up in this fluid. We do not say such currents are normally produced, but it simplifies our discussion if at this stage we are permitted to assume this possibility.

EXPERIMENTAL PHYSIOLOGY—ANIMALS.

By opening the external horizontal canal in a pigeon or rabbit, and blowing through a capillary glass tube which was introduced into the canal, Cyon found nystagmus was evoked; moreover, he observed the character and rate of rhythm of the oscillation of the eyeball were the same as those which Purkinje had described in connexion with post-rotatory nystagmus half a century previously. Ewald repeated these experiments, using a compression and rarefaction syringe and taking the precaution to seal the canal behind the artificial opening. He was thus able to bring pressure to bear on the fluid in the ampullary end of the canal. He found that compression caused the eyeballs to deviate towards the contralateral side, and the nystagmus occurred when the eyes looked toward the ipso-lateral side. Rarefaction produced opposite movements—viz., deviation towards the ipsolateral side and nystagmus when the eyes turned toward the contralateral side. In other words, *the eyes deviated in the same direction as the current, if we may still assume that the current is produced.*

OBSERVATIONS IN THE HUMAN SUBJECT.

In human subjects affected with middle-ear suppuration we not infrequently meet with fistulous openings of the external semicircular canals similar to those artificially produced by Cyon and Ewald in animals. Hinsberg collected 198 examples of such fistulæ from literature, including 22 cases from his own practice, in 1902.[15] Two years ago Mr. West and I described 15 examples which we had met with. As a rule, such fistulæ are more often found only after the membranous labyrinth has become defunct owing to the fact that the symptoms produced by the process of disorganisation of the labyrinth are generally mistaken for some other affection. Occasionally we meet with the fistula while the functions of the membranous labyrinth are capable of direct excitation. During the last three years I have met with nine examples of this latter class of fistula.

LABYRINTHINE FISTULÆ—COMPRESSION PHENOMENA (*9 Cases*).

CASE 1.—A man with a vestibular fistula reeled and nearly fell when the tragus was pressed inwards so as to compress the air in the external auditory meatus. No nystagmus was sought for in this case.

CASES 2 AND 3.—Two women with vestibular fistulæ also reeled with vertigo and nearly fell when the meatus was compressed in a similar way. Violent nystagmus was observed, but its type was not analysed.

CASE 4.—A young man with an external canalicular fistula responded to meatal compression in a similar way. The nystagmus was too violent to allow of analysis being made.

CASE 5.—A boy with a canalicular fistula rotated circus-wise 90° to the contralateral side when pressure was applied to the fistula by means of a jet of water from a syringe. The movement was immediate, involuntary, and occurred when the head was erect.

CASE 6.—A young woman with an external canalicular fistula had giddiness and spontaneous nystagmus to the ipsolateral side. Compression intensified the nystagmus and the existing vertigo.

CASE 7.—An elderly woman had a cholesteatoma and fistula of one external canal which, owing to extensive bone destruction, was visible through the meatus. The slightest contact with a probe upon the fistula produced deviation of the eyes and rotation of the head towards the contralateral side, and horizontal nystagmus when the eyes were attentively turned towards the ipsolateral side. Very gentle meatal compression produced precisely the same results. When the pressure was increased the nystagmus became mixed in type, rotatory as well as horizontal, and it was then impossible to analyse, nor was it possible after repeated trials to aver that rarefaction of the meatus caused the contrary effect to ensue.

CASES 8 AND 9.—The patients were boys with traumatic fistulæ, but no additional datum was obtained.

[15] Zeitschrift für Ohrenheilkunde, vol. xl.

Thus, perhaps in an imperfect way, we are able to show that what Cyon and Ewald found in lower animals is true also in the human subject.

Hughlings Jackson's Case.

Dr. Hughlings Jackson gives an admirable description of what seems to have been a similar condition in a woman, aged 49 years, with mastoid disease due to middle-ear suppuration. Compression upon the meatus caused deviation of the eyes to the contralateral side. Nystagmus with the rapid movement towards the ipsolateral side, and also some rotatory nystagmus.[16]

In another contribution Dr. Jackson described two other cases of ocular movement during a paroxysm of auditory vertigo.[17] He quotes a somewhat similar case of Schwabach,[18] and also of Clarence Blake.[19]

Some years later Charles Kipp described cases of transient bilateral horizontal nystagmus which occurred with purulent inflammation of the middle ear.[20] But in none of these cases, so far as I can gather, was a fistula of the labyrinth actually identified, although Dr. Jackson naturally supposed that the phenomena were the result of direct mechanical stimulation of one or other of the semicircular canals.

Rud. Panse (1902)[21] however, mentions two cases in which meatal compression evoked deviation of the eyes and rotation of the head to the contralateral side, followed by horizontal nystagmus to the ipsolateral side. These observations tally with my own and with Ewald's experiments.

CALORIC REFLEXES.

In the "seventies" Breuer showed that similar phenomena were evoked by the effect of changes of temperature of the outer wall of the labyrinth. Breuer's observations formed the basis of the caloric test introduced to otology by Bárány.

Experiment.—If the ear of a normal person with intact labyrinth and, for preference, with a perforated drum is gently irrigated with tepid water the sensation of vertigo can be produced after a short latent period. The objective phenomena which accompany the state of vertigo depend upon the position of the head. When the head is turned face downwards and the left ear alone is irrigated, directly the vertiginous state begins irrigation is discontinued, the patient is directed to try to stand steady, keeping the face down. This he will not be able to do on account of strong, forced movements which in a typical case cause the head, and generally the trunk and limbs, to rotate circus-wise towards the contralateral side. An examination of the eyes while the head is bowed down reveals the presence of horizontal nystagmus, most evident when the eyes are directed towards the ipsolateral side. In other words, we recognise the same set of phenomena which has been induced by mechanical compression of a fistula of the horizontal canal. The legitimate explanation is that in accordance with the laws of heat by cooling the outer wall of the internal ear, convection currents are set up in the endolymph, which pass from the horizontal canal downwards (because the face is turned downwards) towards the utricle. As before mentioned, Ewald succeeded in producing the contrary reflex movements by rarefaction—i.e., presumably—by inducing currents to flow from the utricle into the external semicircular canal. We can simulate these reversed currents by using hot water instead of cold. As we should expect, when the head is in the face-downwards position, the forced rotation of the head and eyes produced by hot water irrigation is towards the ipsolateral side, nystagmus on fixation being horizontal towards the contralateral side. Thus, as regards the horizontal canal, the hypotheses concerning compression and convection currents are in harmony.

This may be stated in the form of a law: *The deviation of the head and eyes is in the same direction as the current in the endolymph, and the nystagmus is in the opposite direction.*

THE SUPERIOR SEMICIRCULAR CANAL.

Fistulæ of the superior semicircular canal leading into the accessory cavities of the tympanum are very rare, and no opportunities have occurred for watching the effect of mechanical compression or rarefaction in this canal in the

[16] For a full description see Transactions of the Ophthalmological Society of the United Kingdom, vol. iii., p. 201 (1883).

[21] Archives of Otology (Tr.), vol. xxxi., p. 480. 1902.

human subject. Data for consideration can, however, be obtained by use of hot and cold water irrigation. We examine the superior canal with the head erect. Cool water irrigation now causes pleurothotonos, instead of circus rotation. The lateral inclination of the head and trunk is very evident as soon as the feeling of vertigo comes on if the patient attempts to stand with feet together and eyes closed. The direction of flexion is toward the ipso-lateral side and the nystagmus, which is rotatory in type, is contra-rotatory.[22]

Hot water irrigation also produces pleurothotonos, but to the contralateral side, with ipso-lateral nystagmus. The direction of the nystagmus is reversed by inverting the head.

The law of deviation is thus confirmed: *The direction of the reflex forced movements of the head, eyes, and trunk is the same as the current in the endolymph.*

Posterior Canals.

When we come to investigate the posterior semicircular canals we are confronted with the disadvantage that mechanical methods of compression cannot be applied, as fistulæ of this canal have not been met with clinically in the human subject. Moreover, the deep-seated position of this canal precludes any effect from the use of convection currents.

Post-Rotatory Phenomena.

Our difficulties respecting the posterior canals can be overcome by the application of passive rotation, and we shall therefore first refer to a reinvestigation of Purkinje's post-rotatory phenomena. The results are dependent upon the position of the head. When an individual is rotated uniformly in a horizontal plane, with the head in an erect position, certain forced movements follow sudden change in the rate of movement. If the angle of velocity is not less than about 80° per second, sudden cessation produces a negative acceleration. The forced movements produced are best made evident when the patient, with normal labyrinth, attempts to stand up with feet together and eyes closed. In a typical instance it will be noticed that it is necessary to protect the patient from falling, but where space permits definite circus movements are performed. In other words, the patient continues to rotate actively circus-wise in the same direction as that in which he has been passively rotated. If the eyes are examined for nystagmus it will be found that horizontal nystagmus is present when the eyes are turned towards the direction opposite to that of the passive rotation.

These phenomena are in harmony with those observed as the result of compression, rarefaction, and caloric tests, and they are explicable by the inertia laws on fluid currents.

To test the value of post-rotatory phenomena by applying the method described to the superior canals the head must be bowed with face downwards, or may be extended so that the face is directed upwards. In either position the two superior canals are symmetrically placed as regards the plane of rotation. (If we know from other data that there is only one intact labyrinth the head should be rotated with the chin 30° toward the ipso-lateral shoulder, in addition to the face-down or face-up position when we wish to demonstrate the activity of the remaining labyrinth.)

When the rotation is suddenly stopped, as in the previous experiment, and the patient attempts to stand, pleurothotonos is produced instead of circus movements. Rotatory nystagmus is also evident and its direction is opposite to that of lateral flexion.

The results of comparative experimental physiology would lead us to expect that the posterior canals are concerned with rotation movements in a vertical plane.

Experiment.—A normal individual is uniformly rotated as before about a vertical axis, but with the head placed on one side so that the sagittal plane of the head coincides with the plane of rotation. This really represents turning head over heels. On coming to sudden rest the patient is directed to stand with feet together. Assistance will be required owing to the production of powerful opisthotonos, or emprosthotonos, according to the relative direction of passive movement. When the direction of the passive rotation of the head about its transverse axis is towards the occiput, opisthotonos and upward deviation of the eyes are produced. Conversely, emprosthotonos and deviation of the eyes downwards result from passive rotation in the opposite direction—i.e., when the crown of the head moves forwards instead of backwards around the transverse cranial axis. These powerful motor reflexes, opisthotonos and emprosthotonos, are explicable on the assumption that currents are produced in the ampullæ of the posterior canals similar to those described in the external and superior canals. The view that posterior canals are mainly, at all events, concerned with movements of the eyeball in the sagittal plane is also supported by observations made upon a patient some years ago during an operation on the labyrinth. Direct pressure with a seeker upon the ampulla of the posterior canal caused the eyeballs to move, first, slightly upwards and then slowly downwards. All these reflexes are absent if both labyrinths have been removed previously.[23] In the present state of our knowledge, therefore, it seems justifiable to suppose that we can investigate the posterior canal by passive rotation, the superior canals by passive rotation and by calorific methods, and the external canals by rotation, calorific methods, and sometimes also by mechanical compression too.[24]

Mach,[25] with great authority, showed that it was a mathematical error to suppose that the radius of the arc of rotation influenced the inertia in the semicircular canal. I confess to be one of those who were prepared to allow for some influence due to variations in the radius of the arc of rotation, and it seemed in a measure surprising to find clinically that the intensity of the physiological reaction varied only with angular acceleration, but not with tangential speed.[26]

Currents in Endolymph.

The conclusions to be drawn from the foregoing data are in no way vitiated by difficulties in the conception of currents through such small canals. Some variation in diameter of the canals is allowed among different species in the animal kingdom, as a study of Dr. Gray's beautiful photographs of the labyrinths of animals reveals. The production of currents must be dependent upon positive and negative pressures in successive portions of the endolymph. If the gradation of pressure involves the endolymph throughout the semicircular canal one of two things must happen: the shape of the wall of the canal must be altered or there is a flow of fluid until uniformity of pressure occurs; whether there is a flow throughout the canal or not does not affect the possibility of movement of endolymph in the ampulla alone. If normal stimulation of the ampullary nerves is due to temporary change of pressure it must be because this change of pressure has produced a movement in the endolymph. It is only a stage further to suppose that this is accompanied by a movement of the extremely delicate fibrillæ of the epithelial cells of the ampulla.

Normal and Excessive Stimuli.

The controversies on this part of our subject do not appear to me to allow for the distinction between normal stimuli, which regulate normal deviation, and excessive stimuli, which produce forced movements and nystagmus. I wish to side myself, therefore, with those who believe the evidence in favour of the production of currents, and the only explanatory qualification which seems called for is that the actual movement of endolymph may be relatively very slight without negation of the hypothesis. In no case is it necessary to imagine the current flowing rapidly through the semicircular canals, although it is necessary to admit movement of endolymph in the ampulla itself. There is one other point of importance to which reference must be made.

Principal and Subordinate Function.

The physiological reactions differ quantitatively according to the direction of flexion of the cilia in a given ampulla. In the case of the external ampulla currents from the canal towards the utricle produce stronger reflex movements than currents in the contrary direction. On a previous occasion when I went fully into this subject I ventured to think that

[22] The terms "ipso-rotatory" and "contra-rotatory" nystagmus apply to the direction of the rapid movement of the upper meridian of the globe of the eye rotating about the antero-posterior axis of the eyeball.

[23] Cf. Mr. Lake's case, which he courteously allowed me to examine, Proceedings of the Royal Society of Medicine, Otological Section, 1908; Dr. Gibson and Mr. Lake, Ablation of Both Vestibules.

[24] We have noted that E. P. Lyon failed to produce forced movements in the planes of the posterior and superior canals in dog-fish by direct stimulation of these canals with the same certainty as could be obtained in the case of the horizontal canal. Cf. Loeb, Comparative Physiology of the Brain, and Lyon, A Contribution to the Comparative Physiology of Compensatory Motions, American Journal of Physiology, vol. iii., 1900.

[25] Grundlinien der Lehre von den Bewegungsempfindungen, 1875.

[26] Proceedings of the Royal Society of Medicine, Otological Section, p. 41, 1909.

this undoubted difference was dependent upon a physical difference of the relationship of the canal to the ampulla according to the direction of flow.[27] But such physical argument was based upon consideration of the external canal only, and a further study of the problem last year confirmed me that the conclusion is refuted by considering the superior canal. For in cases in which one labyrinth has been extirpated the duration of the post-rotatory nystagmus is longer after rotation in one direction than after rotation in the opposite direction. Currents from the extenal canal to the utricle and from the utricle to the superior canal produce nystagmus of longer duration than can be produced by currents reverse in direction (under otherwise equal conditions).

GALVANISM.

Stimulation of the labyrinth by means of galvanism has been carried out in the lower animals by innumerable experimenters, and it has been shown that the application of the current direct to the labyrinth or to the ampullary nerves, or the eighth nerve as a whole, may cause forced movements and nystagmus. In the human subject similar phenomena, varying in degree according to idiosyncrasy, can be induced by placing one electrode against the tragus and the other in a neutral position. If the patient with normal labyrinth is examined in a standing position, with feet together, or with one foot in front of the other, and eyes closed an imperceptible current is sometimes sufficient to invoke strong involuntary movement. I have found 2 milliampères in normal subjects sometimes sufficient. Usually a current of 3 to 5 milliampères continued for a minute or two will cause lateral swaying of the head and trunk, and in a typical case pleurothotonos is produced. *Stronger currents are necessary to evoke nystagmus* and in this case the patient must be seated. for unpleasant sensations may be produced. The deflexion of the head is towards the anode and from the cathode. The reaction with the anode is stronger than the reaction with the cathode. *The anode pulls harder than the cathode pushes.*

CONCLUSIONS FROM A STUDY OF GALVANIC STIMULATION.

I have found that the method forms a useful supplementary test in some cases, but cannot be employed to take the place of caloric and rotatory tests in all cases. Before any inferences can be drawn it is absolutely necessary to test the effect of anode and cathode separately on each side. As a rule, weak and quite painless currents of less than 5 or 6 milliampères, if continued for a few minutes, evoked forced movements when the labyrinth and its central connexions are normal. It is often impossible to display nystagmus without a strong and painful current of more than 10 or even 15 milliampères in normal subjects.

According to Bárány, galvanic nystagmus is evoked first, while deviation of the body is produced later. (Presumably his patients were always seated.) It will be seen from my experience that the reverse was noticed, if we gradually increase the current and watch the effect of the current on an individual who stands with feet together, as described above. This is also in agreement with Lemaitre and Halphen,[28] and also with Buys and Henebert.[29]

ABLATION OF ONE LABYRINTH.

The extirpation of one labyrinth in an animal produces an immediate effect upon (1) the attitude of the resting state, and (2) the character of the animal's movements in space. These effects in the course of time become less noticeable, and an animal that survives long enough may acquire such compensation that it may pass muster with its fellows without any noticeable defect. The same is true in man. The immediate effect of removing one labyrinth in frogs was studied by Hasse, 1873, who noticed inclination of the head to one side. Schiff, 1891, noticed that when the frog jumped the contralateral limb was partly abducted, and Ewald, 1892, noticed that when the frog was swimming, the body on the side operated upon was lower in the water. He also noticed that the contralateral forelimb was extended —i.e., unilateral ablation of the labyrinth in the frog causes ipsolateral flexion and contralateral extension of the head and limbs. Van Rossem[30] has found the same in tortoises. Ewald, 1892, and Girard, 1892, investigated the muscular tone and found weakness in the limbs on the ipsolateral side. Emmanuel described changes in the muscle curves which are in accord with Ewald's views.

Certain apparently special functions of the vestibular labyrinth have been particularly studied by Ewald[31] and von Stein. Sir Victor Horsley drew attention to an altered attitude during a recent discussion on the subject of vertigo, which led me to watch for the effect in human subjects. Last year Dr. Gordon Wilson, late professor of anatomy, University of Chicago, kindly gave me a photograph of a dog whose right labyrinth he had removed. The photograph showed not only lateral flexion and rotation of the head, but also what might pass unnoticed, abduction of the contralateral limbs.

Schiff investigated the effect of passive rotation on frogs before and after unilateral and bilateral ablation of the labyrinth. His method was to rotate the animal on a disc at a uniform velocity, starting from rest, which, acting as a positive acceleration, produced a reactionary movement of the frog and caused it to turn its head in the contrary direction. During the rotation the frog would remain motionless in its new position, but when the disc was suddenly stopped a reactionary movement was set up by the negative acceleration, which resulted in post-rotatory movement in the direction of the previously rotating disc. To the initial movement or reaction I propose to apply the term "alpha reaction," and to the post-rotatory reaction the term "omega reaction." In the normal frog the alpha reaction is equal to the omega reaction, estimated by the number of degrees to which the animal moves on the disc.[32] These movements do not occur when both labyrinths have been removed, therefore they cannot be due to inertia of the whole body.

UNILATERAL ABLATION.

When the rotation is made to the ipsolateral side the alpha reaction is much weaker than the omega reaction, which is exaggerated. When the frog is rotated to the contralateral side the alpha reaction is much greater than the omega reaction. Ewald found that in normal pigeons the alpha reaction was equal to the omega reaction, but after one labyrinth had been removed the reactions were unequal, like those of the one-labyrinth frog.

Coming to our own experiments, measurement of the alpha and omega reactions under like conditions in the human subject is impossible to carry out satisfactorily with hand-rotation chairs, which though useful for general clinical purposes after some experience, do not possess the mathematical accuracy required for records of permanent value.

As far as it is possible to estimate with hand-rotated apparatus, I am disposed to think that the alpha and omega reactions before and after ablation are similar to those described in animals, differing in degree.

In a normal child on hands and knees on the rotating table the alpha reaction was about 20° and the omega reaction 20° (angular acceleration 90° per second). In two others similar results were obtained. It is the usual experience to find that after unilateral ablation the omega reaction produced by rotation towards the ipsolateral side with the head erect is greater than the omega reaction produced by rotation in the opposite direction.

ATTITUDE.

Since Sir Victor Horsley drew attention to the subject[33] I have noticed the head to be very slightly deviated towards the side of the lesion (I can recall seeing cases some years ago); the angle of deviation from the perpendicular plane was in one recent case 15°. It was also noticed that there was some lateral deflection of the head and trunk towards the same side—*in other words, slight pleurothotonos towards the side of the lesion.*

Besides an altered attitude of the head, there is a change in the posture of the limbs: the patient may stand with feet wider apart. Dr. Risien Russell has mentioned this to be generally observable in cerebellar lesions. This wider base is probably secured not by equal abduction of the limbs, but

by *forced abduction of the contralateral limbs* (cf. Dr. Wilson's dog).

VON STEIN'S TESTS.

After disorganisation of one labyrinth patients sometimes have a sense of weakness in the muscles on the ipsolateral side. This is not always noticed and may soon pass off, but the patient may not be able to maintain the upright position when standing on the ipsolateral leg, although he may be steady on the contralateral leg alone. For the clinical value of this observation, which we have practised in varying ways for some five years, we are indebted to von Stein, who has also shown (and the observation can be easily confirmed) that hopping on the ipsolateral limb is generally impossible in recent infection or disorganisation of the labyrinth, although it may still be possible on the contralateral limb.[34]

HYPOTONUS, DYSDIADOKOKINESIA (BABINSKI), &C.

I have never been able to detect weakness in the flexor to the forearm by the finger-grip test, nor have I been able to obtain the brachial bicipital reaction in labyrinthine infections, described by Stewart and Holmes in cerebellar lesions.[35] I have not found any interference with rapid alternating pronation and supination of the wrist in disorders of the labyrinth. In contrast with cerebellar tumours[36] it is interesting to observe that two cases in which suppuration extended from the labyrinth into the cerebellum showed no such dysdiadokokinesia, nor was this sign present in a third case of cerebellar abscess in which the labyrinth was normal.

Before leaving the vestibular system I should like to draw attention to the further researches of van Rossem, which have led him to calculate the mean reaction time of rotation consciousness. This he estimates to be 0·8 second. If compared with the mean reaction time of other sensations we shall find it rather slow: visual, 0·195; tactile, 0·145; muscular contraction, 0·151; thermal, 0·162; taste, 0·502; and sound, 0·150.[37]

Van Rossem also worked out the minimal perceptible acceleration it was possible to detect. The mean minimal perceptible angular acceleration was 1·36° per second. As far as seemed reasonable, I have attempted in this discourse to restrict the matter to the results of actual experiment and to clinical observations, believing that by adhering to these methods more reliable data may in time accrue. I have also omitted considerations of the action of the utricle and saccule which are probably concerned with acceleration in straight lines, forwards and backwards, upwards and downwards, and possibly sideways.

COCHLEAR SYSTEM.

Ever since the eighteenth century it has been recognised that a fully developed spiral cochlea exists only in mammals; its homologue, the lagena of birds, is comparatively a simple tube and only slightly curved. In reptiles it is quite rudimentary, absent in some amphibians and fishes.

The tympanum with a columella and fenestra rotunda and Eustachian tube are simple in birds and in those reptiles in which they exist; there is *no* tympanum in snakes—e.g., yellow cobra and hoary snake of South Africa. As regards the organ of Corti, there are no rods in the organ in birds, so that they cannot be indispensable structures.[38] The membrana basilaris on which the organ of Corti rests is said to vary considerably in different animals.

In the past it has been assumed—e.g., 1867, John Marshall, "Human and Comparative Physiology"—that practically all animals possess the power of hearing. This is a preconceived premiss which has no scientific foundation and represents a prejudice which dies hard. An amusing account of the supposed hearing power of the garden snail is quoted because it is so extraordinary in the "Cambridge Natural History" (see article on Molluscs). After reading this I kept a number of garden snails under close observation, and when they emerged from their shells they were exposed to the influence of Bezold's continuous tone series of instruments, to which they invariably displayed supreme indifference. Not one of the 16 snails at any time during the two months they were kept ever showed any attraction for, or repulsion from, or stationary attention to, the loudest sounds the instruments were capable of emitting. They were tested with every tone in the series, from 16 to 50,000 double vibrations per second. The instrument was applied to the shell, to the board on which they were crawling, and as close to the body or antennæ as was possible without actual contact. These molluscs are excessively sensitive to touch. Contact with a fine hair will cause instant retraction.

The presence of weak formalin on wool within an inch or so of the body causes the snail to instantly withdraw. Sounds of pure and mixed tones had no such effect. The so-called otocyst in molluscs is much better regarded as a stato-cyst and should be so named. The value of hearing in most fishes, amphibians, and many reptiles is extremely doubtful.[39] It has been assumed rather than proved to exist, except in a few species. Moreover, the tactile sense is so acute in some of these animals that they are possibly, indeed probably, affected by tactual vibrations in the water which surrounds them, or of the ground on which they lie at full length. Such tactual sensations may be set up by vibrations which accompany loud sounds of relatively long wave-lengths.

Some animals, for instance the common fowl, are peculiarly sensitive to tones of a certain pitch, as one can readily prove with a Galton whistle. On the authority of Dr. Plimmer, pathologist to the Zoological Society, a bull-frog was indifferent to the noise of a pistol fired close to it, even its respiratory rhythm being unchanged, yet it is conceivable that it is capable of hearing a monotone of a certain pitch or the croaking of its mates.

Attempts to make investigations into the *modus operandi* of the cochlea must be founded upon an accurate anatomical basis, both normal and pathological, and should be considered side by side with physiological experiments in lower animals, clinical phenomena, and physical laws. It is merely so much guess work to deal with other than ascertained data. Our present knowledge, however, is insufficient to substantiate any full and satisfactory explanation of the function of the cochlea, and we must seek the most acceptable working hypothesis as a basis for further investigations. The problem is reduced to the stage when we wish to ascertain whether sound waves produce a movement of the hairs in the organ of Corti, and if so what is the character of the movement of these hairs and by what direct means is such movement accomplished.

It is thought possible that the motion produced by sound waves on the labyrinth reaches the cells through the fluid of the labyrinth, either through motions in the basilar membrane, or by motion of the membrana tectoria, which impinges upon the free ends of the cilia of the hair-cells. By means of the mechanism of the stapedial foot-plate and the formation of the membrana secundaria which closes the fenestra rotunda, it will be understood that any to-and-fro movement of the stapes, due to compression and rarefaction waves of sound, will cause synchronous movements of the membrana secundaria through the intervention of the perilymph.

Those who have studied the cochlea from the physical aspect conclude that the motion in the perilymph can be no other than mass motion.[40] Such mass movement of perilymph must affect the pressure in the endolymph, possibly in the form of compression and rarefaction waves; otherwise we cannot possibly explain the mechanism of the sound stimulus. We cannot imagine an effectual resistance to changes in pressure in the perilymph from the membrane of Reissner, and although it is by no means clear in what form sound waves traverse the cochlea we must admit a mechanical motion of some kind is produced. But we cannot ignore the fact that sound-waves fall upon the membrana secundaria synchronously with those which reach the stapes—e.g., after removal of the tympanic membrane.

It is assumed that either the basilar or tectorial membrane vibrates; which should be regarded as the essential vibrator is a matter of controversy. If these membranes vibrate, do they do so in part, or throughout their whole length, and to

[39] I have found that rattlesnakes, Indian pythons, South African cobra take no notice of the loudest tones of the three Edelmann whistles (which encompass the upper half of the scale of sound). Green lizards respond to certain tones, frogs do not.

[40] Weber. Von Helmholtz, p. 106. Cf. Sir Thomas Wrightson: On the Impulses of Compound Sound Waves and their Mechanical Transmission through the Ear, 1907.

all sounds, or only to some? Or do they only vibrate in a particular part for a particular sound? Von Helmholtz propounded and elaborated the theory that each portion of the basilar membrane was set into reciprocal vibration by tones of one and only one pitch. Normally, the human subject is capable of hearing about 11½ octaves—i.e., tones of from 16 double vibrations per second up to tones of nearly 50,000 vibrations per second.

Von Helmholtz showed how it might be possible for high tones to cause sympathetic vibration of the basilar membrane at its basal extremity, where the membrane is narrowest radially, and that low tones could produce vibration of the basilar membrane in the apex of the cochlea where it is widest and most lax. Helmholtz distinguished musical notes from noises, and supposed the former were appreciated by the cochlear and the latter by the vestibular apparatus; we have, however, clearer views of the functions of the vestibular nerve than had been admitted in Helmholtz's time; moreover, Albert Gray [41] has successfully shown that noise is not fundamentally different from musical tones, but that the cochlea may appreciate noise just as it does pure tones. Albert Gray's modification of Helmholtz's theory to include the appreciation of noises by the cochlea has been so ably expounded that we must refer to it as the Gray-Helmholtz theory. Essentially it is the application of the principle of sympathetic vibration. If the Gray-Helmholtz theory had maintained that the whole of the basilar membrane vibrates for each kind of sound wave it would not have been possible to explain by it how certain deaf individuals have partial defects in the range of hearing. We know that notes of low pitch are obstructed more easily than notes of high pitch, but how is it that certain deaf persons can hear notes low in the bass and perhaps high in the treble, but are unable to hear even the loudest notes in the middle of the normal auditory field? I have met with a number of such cases in tabes dorsalis and other diseases. An explanation is provided by Helmholtz's theory.

One of the objections raised to the hypothesis as it stands is embryological. As Shambaugh has pointed out,[42] we should suppose that in a special sense organ derived from epiblastic structures the important rôle of stimulating the "hair-cells" would be by a structure of epithelial origin—e.g., the tectorial membrane—and not by one of mesoblastic origin, like the basilar membrane.

An important anatomical objection to the basilar membrane theory is also lodged by Shambaugh, and is also noticed independently by Ter Kuile and Hardesty [43]—viz., that at the lower end of the basal coil of the cochlea in the pig the basilar membrane frequently cannot be found where the organ of Corti is perfectly developed, and also that the organ of Corti, here seen rests upon a solid bony plate which bridges between the lamina spiralis ossea and the outer wall of the cochlea.

Ter Kuile and Hardesty describe the inner pillar of Corti as resting upon the labium tympanicum in the basal coil. The significance of these observations cannot be disregarded; on the other hand, it would be necessary to ascertain whether the animal in which this condition was found showed signs of appreciating as high tones as other animals of the same species in which a basilar membrane for the basal extremity of the organ of Corti was present.

TECTORIAL MEMBRANE.

The possibility of the tectorial membrane vibrating in response to sound waves seems to have been first suggested by Rinne in 1865. It also occurred to Rutherford and to Voltolini, who built up an important hypothesis explaining its action (1885–86). Ewald and Max Meyer suggested modifications in the hypothesis. It was supposed that the basal end of the membrana tectoria would be capable of responding to the impulses produced by high-pitched tones, while succeeding tones, lower in the scale, might respond to larger and larger areas in descending the scale, until the deepest tones would cause vibration of the membrane from one end to the other. Such an explanation fails to account for the ability to perceive separately all different sounds which act upon the ear simultaneously; nor does it account for the presence of defects in hearing known as tone islands and tone gaps in the auditory field. Shambaugh maintains that the principle of sympathetic resonance is applicable to the membrana tectoria, which gradually increases in breadth from base to apex, after the manner of the basilar membrane.

Comparison of the Breadths of the Basilar and Tectorial Membranes.

Basilar membrane.		Observer.	Tectorial membrane.		Observer.
Base.	Apex.		Base.	Apex.	
mm.	mm.		mm.	mm.	
0·21 (man).	0·36	Retzius.	0·12 (man).	0·24	Von Ebner.
0·2 ,,	0·3	Kolmer.	0·08 ,,	0·240	Kishi.
0·041	0·495	Hensen.	0·038 (pig).	0·432	Shambaugh.
			0·046 ,,	0·220	Hardesty.

That there is a difference in the breadth of these membranes passing from base to apex is not difficult to show in histological sections, but it is a matter of extreme difficulty to be sure that measurements made are perfectly radial at the base and at the apex too. Unless special methods are adopted to prevent distortion and contraction of the membrana tectoria, measurements of this structure are of no value, and for this reason I have not added my own figures from specimens passed, e.g., through alcohol, which causes shrinkage of the membrana tectoria.

Hardesty's work on the tectorial membrane is the most praiseworthy. This observer succeeded in isolating the membrane from the cochlea in pigs. Dissections under saline fluid were carried out with the aid of the microscope. He thinks the tectorial membrane is much more qualified to act as a vibrator than the basilar membrane on account of its evident elasticity, transverse flexibility, sensitive to agitation in fluids in which it is examined, and lastly because it is attached along one instead of along both sides.

As a working hypothesis, Shambaugh's application of the Gray-Helmholtz principle of sympathetic resonance to the tectorial membrane is, in the present state of our knowledge, the most satisfactory explanation: possibly we may combine these theories.

Many useless controversies seem to be occasioned by retention of the term "telephone theory," which is surely a misnomer. Every sound, simple or complex, will produce a distinctive effect on the cochlea. All modern theories, call them by what names we choose, are based upon the assumption that the analysis occurs in the "periphery" before it can be appreciated centrally. Those who claim that the membrane vibrates as a whole agree that it must vibrate differently for different sounds—"sound patterns." [44] This is peripheral analysis, as Shambaugh rightly, I think, maintains.

[The lecture was illustrated by lantern slides of microphotographs, charts, and diagrams.]

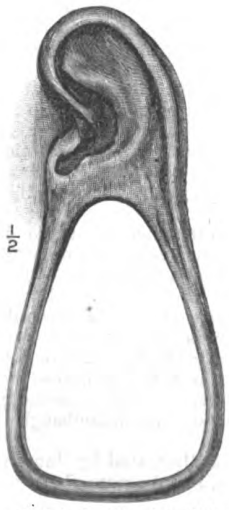
THE TRINIDAD ASSOCIATION FOR THE PREVENTION AND TREATMENT OF TUBERCULOSIS.—The fifth annual report of this association shows an alarmingly high death-rate from tuberculosis amongst the inhabitants of Port-of-Spain. The total death-rate is 26·8 per 1000, while deaths from tuberculous diseases figure at 4·75. The association has a gratuitous dispensary for tuberculous patients, which is worked on the lines of the out-patient department of the Victoria Hospital for Consumption in Edinburgh. The average number of attendances each month was 113 during the last year. Information regarding the prevention of the disease is disseminated by the association, and at the recent Trinidad Agricultural Exhibition a cottage built on hygenic principles was exhibited, together with a replica of one of the many insanitary hovels which are to be found all over the colony. A sanatorium is urgently needed in Trinidad, and the association is urging the Government to build one. The report also draws attention to the necessity of having compulsory notification of cases of tuberculosis.

THE EAR ORNAMENTS OF THE MASAI AND THE NATIVES OF KIKUYU.



BY JOHN BLAND-SUTTON, F.R.C.S. ENG.,
SURGEON TO THE MIDDLESEX HOSPITAL, ETC.

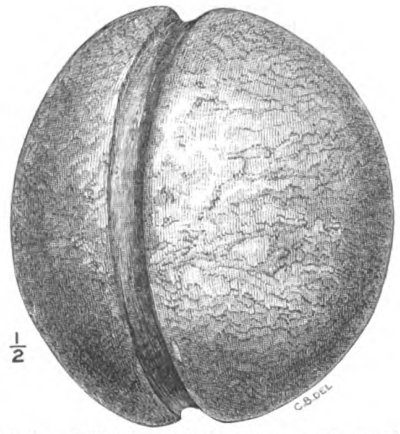
HUMAN vanity assumes many forms and one of its grotesque expressions is furnished by a study of the ear ornaments of the Masai and the Wa-Kikuyu in British East Africa. In a recent visit which I made to this, the latest addition to Greater Britain, in company with my friend and colleague Dr. Comyns Berkeley, I was able to study an extraordinary phase of fashion and deformity.

The various contrivances employed for adorning the ears among mankind may be set down in two classes—ear-studs and ear-rings. As a rule, ear-studs are inserted into the helix and ear-rings into the lobe. In some instances the lobe is converted into a loop for the retention of the ornament. In many civilised countries ear-rings are worn in the lobe, and this style of decoration is usually confined to women. Among the two tribes of natives concerned in this article ornaments are worn in the ear by men and women.

When the boys and girls have passed through their "initiation ceremonies," which means circumcision for one sex and clitoridectomy for the other, the lobe of the ear is pierced and a thin spigot of wood inserted into the hole. Gradually this hole is enlarged by the introduction of thicker pieces of wood until it is large enough to receive a stone with a groove running round it. These stones vary in size, but the ultimate result is the transformation of the lobe into a rounded cord-like loop (Fig. 1), which in the black

FIG. 1.

The ear of Masai; the lobe is dilated until it resembles a ring of indiarubber.



ears of these men and women looks like a ring of indiarubber. Among the Masai the full size is attained when the cutaneous ring of one side will meet its fellow over the crown of the head. Hollis states that the largest stone ear-plug in existence weighs 2 pounds 14 ounces. This stone is represented in Fig. 2 and *in situ* in Fig. 3. It would be thought that the ears of the Masai must be larger than those of other men and women, but this is not the case; indeed, Captain S. L. Hinde, who lived among these people in an official capacity for many months, states that the ear of the Masai when left to itself is small and of good shape.

An examination of some of these enormous ring-like lobes shows that the tissue forming the loop undergoes hypertrophy. When the lobe has been stretched to its utmost capacity it becomes the receptacle of many strange things, such as plugs of wood, rings of horn or of ebony; occasionally a can or a gallipot will be found in it. The ear-lobe of the women is also dilated, and they wear a curious ear-ring, as well as a necklace made of iron wire. These coils of iron wire resemble the firework known as a Catherine-wheel (Fig. 4). Such ear ornaments, known as *'surutya*, are fastened to the lobe my means of a strap of leather with a kauri shell fixed to it.

In addition to the lobe, the helix also is adorned with ornaments of various kinds. In some the ornaments are thrust into holes made in the rim of the ear, or the concha may be slit below the rim of the helix. The helix is perhaps more freely used by the Wa-Kikuyu than by the Masai.

A superficial examination is sufficient to indicate that these ornamented ears had some social or tribal significance. This

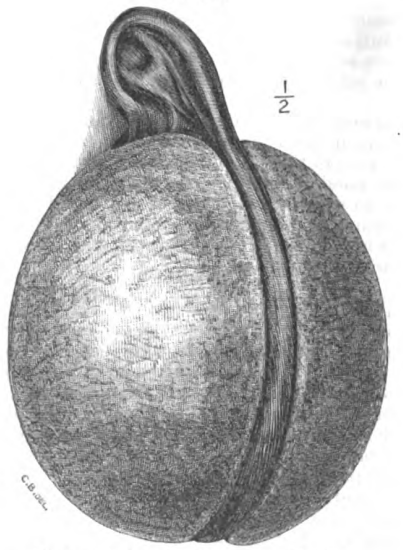


FIG. 2.

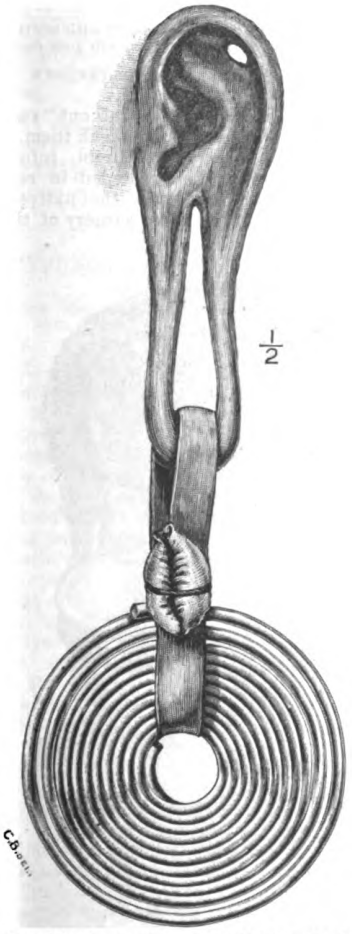
A stone ball, weighing 2 pounds 14 ounces, used by the Masai for enlarging the opening in the lobe of the ear. (British Museum.)

is indeed the case. Hollis has collected some valuable information on this matter. The following sentences from his valuable book are instructive:—The reason why women wear necklaces of iron and ear-rings ('surutya) is in order that it shall be known that they are married. Women's ear-rings are of great consequence, for no woman ventures to leave them off during the husband's lifetime. Should she happen to take them off whilst doing her work, she would, on the approach of her husband run

FIG. 3.

The ear of a Masai with the stone *in situ*.

into the hut and resume them, so that he should not see her without them. If the husband went away from home she would not venture to take her ear-rings off for fear other men should see her without them; they would tell her that her husband would hate her.



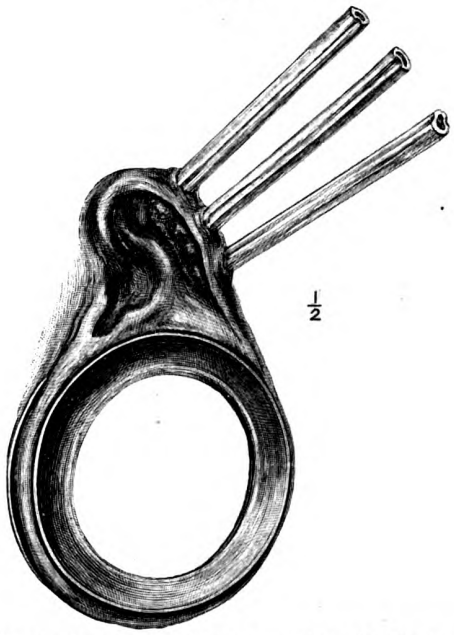
Boys and girls insert blocks of wood into their ear;

warriors and old men wear chain ear-rings. No Masai elder may wear the ear-rings called 'surutya unless he has children who have been circumcised and become warriors. When the father dies the whole family mourns for him; the widows lay aside their ear-rings, necklaces, and beads for a whole year.

Thus it is clear that the ear ornaments are full of significance as representing the age and social state of males and females among the Masai. It doubtless obtains in other tribes, especially among the closely allied tribe, the Nandi.

The men and women of the Kikuyu country devote much care to the decoration of their ears, and like the Masai attach ornaments to the helix as well as to the lobe, but the styles of ear-studs and ear-rings of the Wa-Kikuyu differ in some particular from those of their neighbours, the Masai.

FIG. 4.



The ear of a Masai woman wearing the ear-ring 'surutya. The strap is of leather and the ornament on the strap is a kaurie shell.

The boys when they are nearly ripe for circumcision have the rims of their ears pierced in three places, and through the holes three, and occasionally five, reeds are introduced; these reeds project from the rim of the helix, but lie in the same plane as the ear. (Fig. 5.)

In the case of women five holes are made in the helix. In its simplest form the ornament consists of a piece of grass with a bead of gum at the base to prevent it slipping out. Sometimes the ends of the three reeds are fitted into a piece of leather which lies in the depression under the rim of the helix. Sometimes the reeds are adorned with coloured beads.

The Wa-Kikuyu also distend the lobe of the ear like the Masai and fit into it a cylinder of wood (Fig. 7), a can, or a gallipot (Fig. 8). Objects of this kind are usually seen in the lobules of men. The women prefer to fill the holes in their ears with large rings made of small beads threaded on

FIG. 5.

The ear of a Kikuyu man with an ear-ring and helix-reeds.

thin wire. These bead rings are not only used in the large hole made in the lobe, but the women often have a long slit made through the concha, and rings of beads are fitted into it. (Fig. 6.)

FIG. 6.

A woman of Kikuyu with her ears full of bead-rings. Many of the rings pass through a hole in the lobe, a few thread a slit in the helix.

The women strive hard to get as many rings adjusted to these artificial openings as possible; on one occasion I counted 44 rings in the pinna of a woman; the majority were in the lobe-loop, but a dozen occupied a slit in the concha. Although one of these bead-rings is light, 30 or 40 hang heavy in the ear; in order to keep them comfortably in position a band, ornamented with beads, is fastened to the rings and carried across the crown of the head. Some of the men, when the ear ornament is very heavy, wear a head-band to keep the ear from being dragged down by it.

FIG. 7.

A native of Kikuyu with a wooden cylinder fitted into the lobe of the ear.

The ring which the Wa-Kikuyu insert into the expanded lobe has a groove around its circumference so that the thick rubber-like cord, which represents the lobe of the ear after dilatation, lies in this groove like the tyre on the wheel of a motor-car. Some of these circular bodies are solid discs with designs on their flat surfaces made with small beads. Although there can be no doubt that there is much latitude in the designs and styles of ear ornaments among the Wa-Kikuyu, and that fashions change from time to time, there is great probability that there are social meanings in these various decorations, especially when we learn that the large plugs of the kind represented in Fig. 7 are made from the wood of certain specified trees.

The Wa-Kikuyu are constantly seen in Nairobi, and it is quite common to see attached to the helix of youths and men a flat tab in shape like a leaf which appears to be made of some white metal, like lead, and bearing a mark. It is said they are beaten out of Maria Theresa dollars. These coins were at one time current in the countries along the Nile (Schweinfurth). Some of the boys wear a large safety pin in the helix. This pin is a very useful tool, for the natives employ it to remove "jiggers" from their feet.

In many of the ear ornaments worn by the Wa-Kikuyu iron and chain are used. The iron is obtained from ore found in the district and smelted by their own smiths. These men make iron articles required by the tribes, such as wire, chains, rings, spears, swords, hoes, and the like. The Kikuyu blacksmiths are specially good at making chain which is used exclusively for the purpose of personal ornament.

The iron articles of the Masai are made by the Ndorobo. The smiths are disdained by these "shepherd-warriors" and they live apart from the tribe; nor will the Masai give their daughters in marriage with the blacksmiths, although they allow their wives to be decorated with the ornaments made by the smiths. Since the European occupation of Masailand there has been very little smelting, because it is easy to obtain trade iron and wire by barter, purchase, or theft, especially by the tribes living near the Uganda Railway.

It would be reasonably anticipated, in view of the great trouble, inconvenience, and, no doubt, some physical suffering involved in transforming the lobe of the ear into a rubber-like cord of tissue capable of surrounding a cylindrical jar, or a disc of wood, with a diameter of three or four inches, that these deformed ears are regarded by their owners with pride and their neighbours with envy. This is the case. To break one of these rings of tissue is a great offence. In all countries, civilised and uncivilised, rival beauties are liable to quarrel and even fight desperately; in such encounters each combatant endeavours to ruin the beauty of her rival. Scratching furrows in the cheeks is a common form of revenge. Shakespeare, in his description of the scene in which Margaret, Queen to Henry VI., boxes the ears of Eleanor Cobham, Duchess of Gloucester, makes the angry duchess shriek:—

> "Could I come near your beauty with my nails,
> I'd set my ten commandments in your face."

This is a neat reference to the marks left by ten finger nails.

The Masai women when they "fall out" snatch at each other's ear loops and endeavour to break them. A friend of mine, who practises surgery in Nairobi, informs me that on several occasions he has succeeded in re-uniting ear-loops broken in this way, and the natives have men among them who perform plastic surgery of this kind very successfully.

FIG. 8.

A native of Kikuyu with a gallipot as an ear ornament.

As a result of the British occupation of the Protectorate many Swahili, Masai, and Wa-Kikuyu have been trained as police (Askari) and soldiers (The King's African Rifles). Ear ornaments under such conditions are not wanted, but in order to preserve the ear-loop it is hooked over the helix where it is safe from harm. As soon as the Askari (native policeman) has finished his term of service, usually about three years, he returns to his tribe, abandons uniform, resumes ear-rings, spear, knobkerry (club), and skin; becoming once more an unclothed native, he smears himself with greasy clay, and joins in the village dance.

The love of personal adornment is very great among these people. Schillings tells of a Masai boy who had been many times to Germany and had mastered the language, including the Berlin jargon. On becoming a man he decided to return

to his people, and was subsequently seen by a European who knew him, covered with clay and his hair in long plaits dripping with grease, in company with a Masai in full war dress.

The mutilation of ears is by no means confined to human beings. The ears of cattle, sheep, and donkeys are marked for identification purposes. The ear-marks are of two kinds—branding and slitting. Among the Masai there is for each clan and family a principal mark, and all the cattle belonging to the various members of a family are branded in a special way. There are also small marks by which the actual owner can be recognised. This is also true of the special methods of slitting ears. Some of the ear-slitting designs are curious; on meeting Somali traders with a herd of cattle I always found it amusing to examine the odd patterns cut in the ears of the oxen.

In connexion with this matter it should be borne in mind that in the early days of the Israelites, if a manservant wished to serve his master for ever, a hole was bored through his ear "with an aul" (Exodus xxi. 6). Ear-marking is a very old custom.

Brook-street, W.

A FURTHER STUDY OF SPINAL ANÆSTHESIA IN CHILDREN AND INFANTS.

BY H. TYRRELL GRAY, M.A., M.C. CANTAB., F.R.C.S. ENG.,

CASUALTY OFFICER (LATE RESIDENT MEDICAL SUPERINTENDENT), HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON.

III.—THIRD SERIES OF 100 CASES.

SINCE the publication of my first two papers[1] dealing with this subject, I have employed this method of anæsthesia on another hundred occasions, and again venture to bring forward the results which have been obtained in the third series. I have once more to express my indebtedness to the surgical staff at the Hospital for Sick Children for their readiness to afford me every opportunity to pursue this study, and I have been personally responsible for the administration of the anæsthetic and for the keeping of careful records in every case reported.

In the present series the use of spinal anæsthesia has been more restricted to emergency and severe operations, and it has been employed less often in routine surgical work, for it was felt that, since the value of the method had been appreciated in the surgery of children, a further study of the principles involved, and increased efforts at improvement, should be made, as far as possible, in those cases where its use is specially indicated.

The same principles have been adhered to in this as in the second series of cases—namely, the localisation of the action of the drug to a small area of the spinal nerve roots by the employment of gravity and the use of a fluid whose diffusibility is reduced to a minimum.

In my former papers[2] it was pointed out that three factors were responsible for the distribution of the solution introduced into the spinal theca: (1) diffusion; (2) gravity; and (3) force of injection. For spinal anæsthesia to be of real value it is necessary for all these processes to be well under control in order that the action of the stovaine may be restricted as nearly as possible to the nerve roots supplying the operation area, and also that, by keeping the solution in the spinal theca, absorption of the anæsthetic agent may be reduced to a minimum. For it has been pointed out that absorption of salts takes place in the spinal theca only to a very limited extent, but that, in the neighbourhood of the cranial venous sinuses, osmosis and filtration play a most important part in promoting the rapid absorption of salts introduced into the cranio-vertebral cavity.

Many of the unpleasant complications met with were shown to be consequent, to a very large extent, not only on the changes of blood pressure induced by *osmosis* (and to less extent *filtration*) between the cranio-vertebral cavity and the cranial venous sinuses, but also on the resulting absorption of the toxic agent into the general circulation and the effects produced therefrom. It was further demonstrated that of the three factors influencing the distribution of stovaine within the spinal theca, only the second and third—viz., *gravity* and *force of injection*—were under the direct control of the surgeon; while the first—*diffusion*—played a most important rôle in the causation of the unpleasant sequelæ just referred to, but was not capable of being controlled at all. In my second series efforts were directed towards the limitation of absorption and a more accurate control over the distribution of the injected fluid by the employment of gravity alone, after reducing the factor of diffusion to a minimum. This was effected by using an indiffusible vehicle—dextrin—the percentage of which can be increased or diminished at will without materially influencing the freezing point of the solution; thus it was found possible to confine the action of the stovaine to the spinal theca to a very much greater extent, and also to delay the absorption of the drug into the general circulation for a much longer period. There was consequently a marked improvement in the results obtained in the second series of cases, with this disadvantage, however—*that increased indiffusibility of the solution employed was found to diminish proportionately the duration of the anæsthesia.* For details I would refer to my second paper.[3]

In the present series efforts have been directed towards the maintenance of the improvements obtained in the second series with, at the same time, a prolongation of the duration of anæsthesia. The degree of success obtained is shown in the following statistical review:—

TABLE I.—*Nature of Operations Performed.*

Operations on the trunk:—	
Abdominal, various	8 cases.
Appendicectomy, acute	3 ,,

Operations on the extremities:—	
Acute osteomyelitis (femur)	1 cases.
Amputation (thigh)	2 ,,
Excision of hip-joint	1 ,,
Excision of knee-joint	1 ,,
Fracture of femur	4 ,,
Fracture of bones of leg	2 ,,
Whitman's operation (talipes calcaneus)	1 ,,
Unclassified	10 ,,
	22 ,,
Failures	4 ,,
Total	100 ,,

In Table I. is given a list of the various operations performed, and it will be seen that these are of a more severe and serious nature than in the first two series. Many of the abdominal operations were in very young children or infants, and were of such a severe and exhausting nature that, in all probability, they could not have been successfully performed under general anæsthesia. In addition to the routine cases of appendicectomy and intussusception, special mention may be made of the following cases:—

1. Resection of part of the iliac and the pelvic colon with lateral anastomosis, in a case of congenital dilatation of the colon associated with recurrent volvulus, in a boy aged 2 years and 7 months. The operation lasted 1 hour and 10 minutes; the child was extremely comfortable throughout and showed no evidence of shock.

2. Anastomosis of part of the bladder and the ureters with the pelvic colon for ectopia vesicæ in a boy aged 5 years. This operation involved a considerable amount of tedious dissection, and the abdominal cavity was exposed for over 1¾ hours. Three injections (9 cgr. stovaine) were given, and at the conclusion of the operation the boy was a little pale and exhausted, and showed some

[1] THE LANCET, Sept. 25th (p. 913) and Oct. 2nd (p. 991), 1909.
[2] Loc. cit.
[3] THE LANCET, Oct. 2nd, 1909.

evidence of stovaine absorption, as indicated by drowsiness, pallor, and two small vomits; his pulse, however, was strong and regular, and his general condition was excellent in view of the severity of the procedure in so young a subject.

3. Two cases of fæcal fistula into the small intestine, the cure of which, in both instances, demanded a severe operation. In one of these patients (a child aged 5 years) an extensive resection and lateral anastomosis of small intestine, together with closure of the blind ends, occupied over 1¾ hours, and the progress of the case was extremely satisfactory.

4. A case of multilocular mesenteric cyst of the great omentum and transverse mesocolon, completely filling the abdomen and extending into the pelvis of a child aged 1 year and 8 months. The removal of this cyst, which had become acutely congested, involved the resection of about 4 inches of the transverse colon with lateral anastomosis, and at no time were there any symptoms of shock.

5. A case of intussusception in which resection and anastomosis was performed on a child aged 7 months, details of which have recently been reported by Fairbank and Vickers.[4] Instances might be multiplied where the employment of spinal anæsthesia has rendered possible the hopeful undertaking of operations which, under general anæsthesia, had hitherto been regarded in a most serious light, so great is the diminution of the shock sustained.

A glance at the list of operations on the extremities will suffice to show that many of these were also of a severe nature and of a class usually attended with a considerable amount of shock in the case of children. This series of cases shows clearly that, as far as the factor of shock is concerned, the surgeon can devote his whole attention to the operation without the distraction of this additional anxiety, which is often so prominent under general anæsthesia.

Four failures (4 per cent.) are reported in this series:—

1. An infant 12 hours old. This was a case of imperforate anus, and I was anxious to ascertain the degree of difficulty in submitting an infant of such small size to spinal anæsthesia. I was not able to get the needle into the spinal theca.

2. In one case the needles were found to be much blunted, and this, as experience has shown, is not at all an uncommon cause of failure.

3. In the remaining two cases the puncture was apparently perfect, no blood was seen, and a free flow of cerebro-spinal fluid resulted in each instance. I am unable to find any reason for the failures in these two children.

In view of these facts I think failures in routine work may be stated at 2 per cent.

If Table III. be referred to it will be seen that general anæsthesia was employed on 7 occasions: (1) 4 of these cases were the failures just reported; (2) in 2 cases the anæsthesia induced was not high enough for the required operation; and (3) on one occasion a whiff of chloroform (for under a minute) was administered for suture of the skin in an operation which had lasted over 1¾ hours.

General anæsthesia was therefore substituted in 6 per cent. of cases, and this figure could have been reduced still further by the administration of a second injection; this will often be attended with success where the first injection has proved unsatisfactory.

I have to report 1 death under anæsthesia, and I am particularly anxious to call attention to the details of this case in view of the various reports which have been published on insufficient information. Mention of this accident (my 254th case) was not made in the previous reports as they had already gone to press.

A boy, aged about 1 year and 4 months, was admitted for a very large tumour in the left side of the abdomen extending well into the left flank and encroaching on the thoracic viscera. The abdomen was enormously distended and the thoracic contents were markedly displaced upwards. So great were the pain and respiratory difficulty that sleep was impossible, and the child was kept under small doses of morphia for the three days immediately preceding operation. Exploration was decided on with the object of relieving, if possible, the distressing condition, and the surgeon, Mr. G. E. Waugh, decided on operating under spinal anæsthesia, as he considered death was practically certain under general anæsthesia. An injection of morphia (1-20th grain) was given immediately previous to operation. Owing to the size and situation of the tumour it was essential to induce paralysis to the level of the third or fourth dorsal segment, and the usual technique of administration was adhered to. Respiratory embarrassment was apparent after about four minutes; shortly after this breathing ceased before the commencement of the operation and could not be restored. In addition to the usual methods of re-animation the spinal theca was flushed out with a strong solution of bicarbonate of soda, but without success.

At the necropsy both lungs were found completely collapsed and a pneumothorax was present on both sides, a condition which was not capable of satisfactory explanation. In addition, the left side of the diaphragm was extensively infiltrated with malignant new growth extending into the left pleura; there were several nodules on the under surface of the right side of the diaphragm and metastatic deposits in various other regions. The growth was not a renal, but a retroperitoneal, sarcoma involving the kidney, pancreas, &c.

There are, as experience has shown, *two real dangers* in administering a spinal anæsthetic to cases where marked abdominal distension is a prominent feature: 1. The danger of respiratory embarrassment if it is necessary to paralyse any of the intercostal muscles. For this reason, as has been previously remarked,[5] in such cases the anæsthesia should be regulated to the lowest level compatible with the operation to be performed. 2. There is the additional difficulty if the abdomen is very large, of arching the back of the patient sufficiently to regulate the height of the paralysis with accuracy.

It should always be remembered that the usual tendency is for the paralysis to result at a rather higher level than that intended, and, therefore, in cases like the one just recorded it is wise to aim at a somewhat lower level of paralysis than that which is actually required. This difficulty was noted quite early in my experience, and I was fully alive to it in the present instance.

The results of this series of cases again bear out the value of spinal anæsthesia in the surgery of children, though the method is naturally not without attendant disadvantages. It now remains to show what measure of success has attended efforts to minimise stovaine absorption and other minor sequelæ and complications, without endangering the practical value of the method, by the employment of solutions of varying composition. The composition of the various fluids used in this series is given in Table II. Mr. W. Peck, chemist to the Hospital for Sick Children, has again prepared all the solutions employed.

TABLE II.—*Composition of Fluids Employed.*

—	Dextrin.	Stovaine.	Suprarenin or adrenalin borate.	Saline or water to 100.	Novocaine.	Strychnine hydrochloride.	Magnesium sulphate.	Hydrochloric acid.
D.	4 %	4 %	Adrenalin borate 0·005 %	Saline.	—	—	—	—
D1.	5 %	3·5 %	Suprarenin 0·005 %	,,	—	—	—	—
D2.	6 %	3 %	,,	,,	—	—	—	—
D3.	6 %	3 %	Suprarenin 0·0075 %	,,	—	—	—	—
A1.	6 %	3 %	—	,,	—	—	—	—
C.	2 %	5 %	—	,,	—	—	—	0·5 %
G.	4 %	—	—	Water.	5 %	0·0125 %	0·5 %	—

The beneficial effect of dextrin as a colloid vehicle was demonstrated in my former paper, both in that it prevents to a large extent faintness due to diffusion and to consequent cerebral anæmia, and also in that it minimises and delays the absorption of the anæsthetic agent into the general circulation by keeping it almost entirely in the spinal theca by the position of the body. Dextrin has, therefore, been a constituent of all the fluids employed. It was, however, shown that the duration of the anæsthesia varied inversely with the indiffusibility of the fluid, and therefore efforts to increase the length of time of the paralysis have been made by adding the adrenal derivatives to the solution.

* Two consecutive injections on one child for one operation counted as two cases. † Child, 10 years and 11 months old, had small injection of 4/5 cubic centimetre. ‡ In two cases vomits were certainly due to anæsthesia. The third case had three consecutive injections; operation 1 hour 55 minutes (see §). In the fourth case vomiting, ? due to dragging on stomach in reduction of intussusception. § Ectopia vesicæ; operation 1 hour 55 minutes; vesico-intestinal anastomosis (see Tables I. and IV.). Second case joint sulphured; child very ill. ‖ All abdominal cases except two herniæ. Five of the abdominal cases were either acute or very severe. ¶ One case 35 minutes excluded, since anæsthesia was not complete. ** Under 2 years. †† 11 years. ‡‡ Extreme toxæmia; two cases were markedly cyanosed also.

If Table III. be now referred to, the comparison of the results of varying the proportion and nature of these ingredients will be found tabulated. It will be seen that novocaine and strychnine were tried on four cases, but with such unsatisfactory results that no further trial was made of this fluid.

Now in the whole series there was only one case in which vomiting was a prominent feature. In all the other cases where vomiting is reported the act amounted to one or two efforts, with the usual result that one or two drachms of fluid were brought up. The attack rarely lasted more than 30 seconds and only amounted to an unpleasantness of no significance. All these vomits have been entered under "vomiting" in the tables.

Nine cases (or 9 per cent.) vomited during the operation. In some of these (as shown in the notes to Table III.) the phenomenon could not be attributed to the anæsthesia alone; while in others repeated injections, for very long anæsthesia in prolonged operations, gave time for the commencement of the "delayed absorption" of the stovaine, and one or two small vomits resulted. Several factors would appear to influence the onset of this symptom.

(*a*) In the first place, the *psychical factor* must be recognised. Evidence in support of this is to be found in the fact that 2 out of 28 children of two years or under vomited during operation (7 per cent.). Both of these children, however, were operated on for intussusception, and on these occasions vomiting was probably induced to a large extent by traction on the stomach during reduction; certainly this seems to have been the explanation in one case, for it is not unusual for the stomach to be distended under spinal anæsthesia. There was, therefore, no case of this age where vomiting could be attributed to the anæsthesia alone.

The remaining cases, 7 in number, were all over 5 years. There were 41 children in the series over 5 years, and the percentage of cases at this age which vomited during operation is consequently 17. It is clear, therefore, that age is an important factor, and the figures adduced support to some extent the view that vomiting is, partly at any rate, psychical in origin. Again, in favour of this opinion is the fact that with many of the older children who complained of nausea, vomiting could be largely checked by an effort of will; some children complained of nausea (actual vomiting occurred in one or two isolated cases in the first two series) after the hypodermic puncture or immediately after the intradural injection, before the onset of any paralysis or the possibility of any stovaine absorption, while others complained that the smell of the theatre made them feel sick.

(*b*) Another factor in the causation of vomiting is the extent of the paralysis induced. When the intercostal muscles are paralysed to any extent (as in operations above the umbilicus) the diminished amplitude of respirations is compensated for by over-action of the diaphragm which presses upon the distended stomach and induces momentary retching. If food is present in the stomach, or if the patient has been fed during the operation, these contents will be returned; otherwise the attack rapidly subsides as the subject becomes accustomed to the new condition of affairs. Table IV., when read horizontally, shows the variations in

* Very severe radical cure of fæcal fistula. † Pyæmia. Child very ill; unconscious. ‡ (1) Case with three injections. Operation 1 hour 55 minutes (see § Table III.). (2) Case of resection. Fæcal fistula. Operation 1½ hours. § (1)? Not due to stovaine. (2) Traction on stomach. ‖ One case of very high paralysis. ¶ Resection; anastomosis; two injections. ** Both high paralyses.

such complications with the extent of the paralysis when the same solution is employed, and gives support to the above statements. When read vertically the value of the different fluids, when used on similar cases, is indicated; this will be referred to later.

(*c*) Again, there is a certain degree of fall in the general blood pressure consequent on the flaccid paralysis over the area involved and the resulting tendency to venous stasis. I do not think this is a factor of great importance, but it certainly must be considered as a possible accessory causation.

(*d*) Finally, stovaine poisoning, from absorption of the drug into the general circulation, is all important.

Now the first factor can be much modified by the treatment of the child. The person appointed to look after the patient should be one known to him, or at least skilful in management of children. This is of great importance, and considerable differences in results are apparent under different management. Further, curiously, vomiting during operation is more frequent in boys than girls in the proportion of 8 to 1 (the proportion of males to females in the whole series was as 3 to 1), and it would seem that special care should be taken in the management of boys. Children who are very ill require little management at all.

The second factor is more or less dependent on the height of the paralysis and the severity of the operation, as shown in Table IV. Vomiting due to this can be prevented to a very large extent by the preparation of the patient; but when present it is insignificant, of short duration, and of no great disadvantage either to patient or to surgeon. The attack commences about 10 to 15 minutes after the injection, can be anticipated, and measures taken to prevent any obstacle to the course of the operation.

As regards the effect of the changes in blood pressure, these can again be influenced by the raised pelvis position, the administration of saline solution, and, in urgent cases if necessary, by bandaging the limbs.

Of far greater importance is the question of toxic symptoms from stovaine absorption and poisoning, and it is towards the abolition of these that attention has been specially directed; when present, these may occasionally be quite alarming, even in routine cases, and they cannot be anticipated as far as present knowledge goes. The symptoms of stovaine poisoning from absorption have, in this series, been reduced to a minimum, as may be seen by consulting Table III.

It will be evident that solution G (containing novocaine and strychnine, see Table II.) was the most unsatisfactory combination employed, and its use was soon discontinued. Solutions A1 and C were not employed in many operations as it was found they did not materially increase the duration of anæsthesia, and so were of no special advantage. In the remaining cases, embracing nearly all the series, dextrin-stovaine solution was combined with adrenal derivatives (D, D1, D2, and D3). These have given much greater satisfaction, and the results demand a brief consideration.

In Table V. the vomiting and retching which occurred, whatever the cause, are tabulated. It will be seen that it was extremely rare for these symptoms to be more than a very temporary unpleasantness for surgeon and patient. In those few instances where the complications were severe, it has been shown that, with one exception, there were several factors involved. And it was evident from a study of the whole series that use of the adrenal derivatives had much to recommend it.

TABLE V.—*Vomiting and Retching.*

During and after operation. Total cases = 40 or 41·6%.	I. Vomited during operation. 9 cases or 9·3%.	(*a*) One vomit	6 cases (= 6·2%).
		(*b*) Four vomits	1 case (= 1%).
		(*c*) Not stated	2 cases (= 2%).
	II. Vomited after operation. 17 cases or 17·7%.	(*a*) One vomit	8 cases (= 8·3%).
		(*b*) Two vomits	3 ,, (= 3·1%).
		(*c*) Three ,, ...	1 case (= 1%).
		(*d*) Not stated	2 cases (= 2%).
		(*e*) Severe and repeated	3 ,, (= 3·1%).
	III. Retched during operation. 14 cases or 14·6%.	(*a*) Retched once... ...	13 cases (= 13·5%).
		(*b*) ,, twice ...	1 case (= 1%).

Now, of these derivatives adrenalin borate was employed in solution D (Table II.). As was anticipated, the duration

of the anæsthesia was prolonged; for in 19 cases an average dose of 3·7/5 c.c. of the solution (containing 2·96 cgr. stovaine) gave an average anæsthesia of 58 minutes, which is an improvement on any of the dextrin solutions hitherto employed. The following disadvantages are shown in Table III. In the first place 75 per cent. of patients showed unpleasant symptoms as the result of its use, while toxic absorption was present to a mild degree in 37·5 per cent. These complications were attributed to the irritating nature of the adrenalin, to which property may also be due the large percentage of headaches after operation (18·75 per cent.). Suprarenin was therefore substituted in solutions D1, D2, and D3 (Table II.) in varying proportions. If Tables II. and III. be studied in conjunction it will be found that some interesting information is forthcoming as a result of the use of these solutions.

As regards the duration of the anæsthesia, it is evident that the higher percentage of stovaine with a lower percentage of dextrin is of no advantage (the quantity of the suprarenin being constant); while, from the point of view of sequelæ, Table III. shows that such an increase in the quantity of stovaine administrated is distinctly disadvantageous. For with D1 74·9 per cent. of patients exhibited symptoms during operation, while 8·3 per cent. suffered from slight headaches afterwards, both figures being considerably higher than those of solutions D2 and D3. Again, the results of increasing the percentage of suprarenin from 0·005 to 0·0075 per cent. are tabulated under D3. This alteration is of no value from the point of view of the length of anæsthesia obtained, while, from the point of view of sequelæ, the balance is in favour of the smaller percentage as employed in D2. For if Table IV. be again referred to it will be evident that a greater number of serious and severe operations was performed in the series D2 than in D3, a fact which is not evident in Table III.; and consequently other contributing factors, apart from the anæsthetic, played an important part. (See Table III., notes ‡, §, and ‖.) In the relative comparison of the fluids D1, D2, and D3, Table IV. further shows that a much larger percentage of operations in D2 were upon the abdomen, and in these, therefore, paralysis to a higher level was necessitated. This has been shown to be one of the most important factors in inducing retching, respiratory pallor, &c. (See Table IV., read horizontally).

Taking all the facts into consideration it is evident that D2 has proved very much the most satisfactory combination employed, and consequently it has been concluded that this fluid (dextrin 6 per cent., stovaine 3 per cent., suprarenin 0·005 per cent., saline to 100) is the safest, will give the least discomfort to the patient, and the best anæsthesia for the surgeon. It is now prepared ready for use by Messrs. Martindale.

The following conclusions may, I think, be made relative to the use of this fluid:—The low percentage of stovaine renders toxic symptoms due to the absorption of this drug unlikely and rare; this unpleasant danger is minimised still further by the addition of the high percentage of dextrin, as shown in the previous series. Suprarenin is not so irritating as adrenalin, so that symptoms due to this property are absent; further, it has the advantage of helping to diminish absorption by lessening the vascularity of the part, and so localises the effects of the stovaine. In addition to these advantages suprarenin prolongs the duration of the anæsthesia, as shown in Table III., and therefore counteracts the effect of the dextrin in this respect. These conclusions are supported by a study of the tables, where another striking feature is also evident.

It was pointed out in the report on the second series that dextrin delayed the absorption of stovaine, and in support of this it was shown that whereas toxic symptoms were often pronounced during operation when stovaine-glucose was employed (first series), these were either absent or negligible when dextrin was used as the vehicle; such symptoms as were present manifested themselves some time after the conclusion of the operation and after the return of sensation and power. These features were also evident in the present series, as shown in Tables III. and VI. Table VI. gives the percentages of cases in which these after-effects were present; and it will be seen that vomiting after operation occurred in quite a fair number. These vomits, however, were in nearly all instances almost negligible and in no way comparable with the vomiting after general anæsthesia (see Table V.). Headache was never severe enough to require treatment and never lasted longer than an hour or two. Of the remote sequelæ, reported from time to time by various authors, there are none to report in this series; statements to the effect that such sequelæ are induced by the adrenal derivatives are not supported by my own experience.

TABLE VI.—*Immediate and Remote Sequelæ.*

—	Vomits after operation.	Severe headache (requiring treatment).	Slight headache.	Paraplegia and incontinence.
D.	7 = 41%	—	3 = 17%	—
D1.	2 = 16%	—	1 = 8%	—
D2.	6 = 20%*	—	= 3%	—
D3.	2 = 8%	—	1 = 4%	—
A1.	0	—	0	—
C.	0	—	0	—
G.	1 = 25%	—	0	—

* Two children very ill before operation.

Conclusions.—A. *Technique and management.*

1. The puncture should be made in the second or third lumbar intervertebral space after the preliminary anæsthetisation of the skin with eucaine (3 per cent.), the patient being in the lateral position.

2. The child should be immediately turned over on the back and the pelvis raised for about 15 to 20 seconds, always remembering to keep the head and shoulders elevated. By this means the heavy dextrin carries the stovaine to the lowest point; this can be regulated by the curve of the back.

3. The preparations for operation may be commenced directly the child has been turned on to the back, for by the time these are completed anæsthesia will be sufficient to make the incision.

4. *The level of the paralysis* is regulated: (*a*) *By the bulk* of fluid used—the larger the bulk of fluid the higher will be the resulting anæsthesia; and (*b*) *by the position* of the patient, as already explained.

5. *The duration of the anæsthesia* can be regulated to some extent by: (*a*) *The quantity of stovaine administered.* This is shown in the middle columns of Table III., but the figures here need some amplification. Thus, with fluid D1 3/5 c.c. and 4/5 c.c. produced an average anæsthesia of 64 minutes, while a dose of 5/5 c.c. only induced paralysis for 48 minutes. This apparent discrepancy is accounted for when it is realised that all the cases which had 5/5 c.c. (three in number) required a high paralysis for operations on the intestines; for it has been previously shown that, not only is a larger bulk of fluid required for the injection in abdominal work than is necessary in operations on the pelvis and extremities, but also that anæsthesia disappears from above downwards, and therefore does not last as long above as below.

(*b*) *The height of the paralysis*, and consequently the bulk of fluid administered. The higher the anæsthesia extends, the longer will any part below this level remain anæsthetic.

(*c*) *The completeness of the paralysis.* If the needle is not accurately introduced, so that the whole of the distal lumen is well within the spinal theca, a variable and incomplete paralysis may result which, though possibly sufficient for the operation required, will not last as long as a similar dose introduced well within the theca. This fault in the puncture may lead to unsatisfactory results, even though a free flow of cerebro-spinal fluid is obtained; for it must be remembered that the point of the needle may just puncture the dura, with its point only, on the anterior aspect of the space, after penetrating the posterior layer; and that, when the cannula is introduced, its point may then lie *outside* the space. To avoid this: (1) The needle should always be withdrawn, after the puncture, to the greatest distance which permits a free flow of cerebro-spinal fluid; (2) the face of the needle point should not be very oblique, but should form a fairly large angle with the axis of the shaft; and (3) the point of the needle should pentrate the dura in the mid-line.

6. *Retching* is to be anticipated if paralysis has involved many of the intercostal muscles. Its onset may be expected from 10 to 15 minutes after the injection, and the phenomenon will rarely last longer than from 30 seconds to

1 minute. This complication has to be reckoned with in high anæsthesia, and since the time of onset is fairly constant the surgeon is given opportunity to guard against any undesirable consequences arising from it.

7. "*Respiratory pallor.*"—This is to be expected in a mild degree when the paralysis is high enough to alter the character of the respirations. It is transitory in nature, being easily restored almost to the normal by brandy or by otherwise stimulating the patient, and so inducing a forced inspiration by the overaction of the upper intercostal and accessory respiratory muscles. This manifestation is of quite a different nature from the livid pallor, sweating, and dilated pupils seen in stovaine poisoning. Another factor in the causation of a slight change of colour is the fall in blood pressure which occurs about 20 minutes after the injection. Dr. L. G. Parsons and the writer are at present investigating this point, and hope shortly to bring forward the results obtained; in desperate cases this factor must be guarded against in the manner indicated (*vide supra*).

8. *Feeding* during operation is permissible and even advisable in some cases when anæsthesia is not required above the *tenth dorsal segment*. If the paralysis is higher than this, feeding is contra-indicated because in high paralysis the stomach is usually distended (sometimes to a considerable extent), and in this condition the presence of food is liable to induce vomiting.

9. *Management.*—Older children should be advised as to what they may expect, and they should be warned of each necessary manipulation before this is commenced. In younger children and infants the surgeon must rely on the speed with which he can carry out the manipulations, so that the puncture can be made and the injection given before the child is well aware of what has taken place. It is unusual for the resulting disturbance to be as great as in the administration of a general anæsthetic, while many children do not know that anything has been done beyond the hypodermic injection of eucaine. In children of all ages success, from a psychical point of view, depends very largely on the management of the patient by the sister or nurse responsible. Fortunately, children who are very ill, when spinal anæsthesia is specially called for, never give any trouble or anxiety in this respect.

B. *Advantages to the Patient.*

1. *Control of surgical shock.*—There is no question that this formidable factor in grave operations is very much reduced, and the prognosis in such cases is correspondingly improved. This is shown by the improvement in the results of emergency and exhausting operations at Great Ormond-street since the adoption of spinal anæsthesia. Dr. Parsons and the writer believe that, so long as the anæsthesia is *complete* (as is the case when fluids of a low diffusibility are distributed over a small area of the nerve roots), surgical shock is altogether absent, but that, when the effect of the stovaine on the nerve roots begins to wear off and *anæsthesia* passes off into *analgesia*, signs of shock begin to appear. (See case of Fairbank and Vickers.) Though there is not sufficient evidence at present to be definite, it seems that the value of the method in controlling shock lies in the *completeness* of the paralysis which is obtained with fluids of low diffusibility acting over a small area; and that methods inducing analgesia only over a large area, by the administration of highly diffusible fluids as recommended by Jonnesco, can have very little advantage over general anæsthesia as regards the mitigation of shock.

Again, in serious collapse the specific gravity of the cerebro-spinal fluid is probably raised owing to the loss of fluid sustained by the patient,[6] to the feeble action of the heart, and therefore the lowering of the general blood-pressure, or to both these factors. Consequently such diffusion and absorption as may ordinarily take place is less likely to do so in collapsed patients, and I have noticed that such slight symptoms as are manifested from time to time are less often seen, and when present are of a slighter degree in collapsed than in healthy subjects. Though it is not possible to be definite, I am inclined to think that this relation holds true also of weakly and plethoric subjects when both in average health.

2. The slight attack of vomiting after operation, usually limited to one or two acts, may be neglected; and it may be considered that absence of this unpleasant manifestation, so often a severe and occasionally dangerous sequela of general anæsthesia, is a point greatly in favour of spinal anæsthesia. This particularly applies to those cases whose after progress is jeopardised by the onset or persistence of vomiting.

3. *Pain* after operation is very much less prominent than when general anæsthesia has been employed; so marked is this feature that it is quite unusual for the administration of any sedatives to be necessary. Restlessness, therefore, is much diminished and, consequently, the conditions which favour healing of the tissues are greatly improved.

4. The danger of post-anæsthetic pneumonia, bronchitis, acute pulmonary phthisis, "delayed chloroform poisoning," &c., is much diminished when spinal anæsthesia is employed; consequently its use is indicated if possible in subjects of pulmonary disease and, possibly also, of cyclic vomiting. Its use is further indicated in long operations on those suffering from cardiac lesions, since the absorption of stovaine can be so markedly delayed that a full anæsthesia can be obtained with a minimum risk of depressing the action of the heart by the direct effect of the poison on the cardiac muscle—a serious risk in chloroform anæsthesia. Presumably also the risk of accidents in subjects of "lymphatism" is diminished.

C. *Advantages to the Surgeon.*

These, of course, embrace any advantages accruing to the patient. But, in addition, the absolute flaccidity of muscles may be mentioned, for freer access to a given part is thereby rendered possible through a smaller incision, while manipulation is correspondingly simplified. Hæmorrhage is also diminished, since the paralysed parts become distinctly anæmic. These factors add considerably to the speed and accuracy of an operation, and this is of importance in those cases where success depends largely on rapidity. For it is in this class of case that spinal anæsthesia will often be called for.

Again, in abdominal work, apart from the ease with which a small incision can be pulled from one side to the other (owing to the extreme flaccidity of the muscles), and so access to different parts of the abdominal cavity can be simplified, manipulations are facilitated by the diminished tendency for the intestines to protrude from the wound. This is of special advantage to the surgeon in cases of intestinal obstruction, and, in all cases of abdominal distension, renders the final suture of the peritoneum a comparatively easy procedure without assistance. Under general anæsthesia muscular relaxation to a corresponding extent would be highly dangerous and, in emergency work, would cause the death of the patient. Again, the definite anæmia and flaccidity of the bowel wall under spinal anæsthesia are often of great assistance in intestinal work; in cases of intussusception reduction is much simplified and much manipulation is saved—a great factor in the improved prognosis of such cases. This feature has been noticed by others who have operated on intussusceptions under spinal anæsthesia.[7] Other minor advantages may appeal to individual surgeons in special operations, but it is not necessary to refer to these.

Such disadvantages as are consequent on the use of this method are very greatly overshadowed by the advantages to patient and surgeon in certain cases. I believe that spinal anæsthesia is urgently called for on all occasions where the after progress of a case is likely to be influenced by shock during operation, and often in cases when its employment is of definite assistance to the surgeon in doing his work as perfectly as possible.

Harley-street.

[6] THE LANCET, Oct. 2nd, 1909.

[7] Fairbank and Vickers: Loc. cit.

THE HEALTH OF DEVONPORT.—The medical officer of health of Devonport (Mr. O. Hall), in his annual report for 1909, gives the population of the borough as 83,103, the area being 3176 acres, with 9775 inhabited houses. 968 deaths were registered, making a death-rate of 11·6 per 1000, the lowest ever recorded in Devonport. 2163 births were registered, corresponding to a birth-rate of 26·1 per 1000. The zymotic death-rate was 1·1 per 1000. The infantile mortality was 95·2 per 1000 births, against 116·7 in the preceding year. Mr. Hall urges the appointment of a health visitor.

CASE OF PAPILLOMA CAUSING HYDRONEPHROSIS IN A HORSE-SHOE KIDNEY.

BY JOHN MORLEY, M.B., CH.B. VICT.,
DEMONSTRATOR OF ANATOMY, MANCHESTER UNIVERSITY; LATE HOUSE SURGEON, MANCHESTER ROYAL INFIRMARY.

I AM indebted to Professor G. A. Wright, under whose care the patient was in the Manchester Royal Infirmary, for permission to publish the following notes.

A man, aged 32 years, an outdoor telegraph worker, was admitted to the infirmary on Feb. 8th, 1909, complaining of a swelling in the left loin associated with hæmaturia. The patient gave the following history. His health had been excellent until some four months back, when he first noticed that his urine was abnormally dark and coffee-coloured. In the course of a month it began to show a distinct red colour like blood, and this condition had persisted without much change in intensity ever since. There was no increased frequency of micturition nor any pain associated with the act. About six weeks before admission he began to suffer from occasional twinges of pain in the left loin shooting down to the groin and coming on independently of micturition or defæcation. This drew his attention to a swelling in the left loin and led him to seek medical advice. The pains had become somewhat worse since, but had never been very severe. The swelling had increased steadily without intermission, and the quantity of urine had been constant throughout, as far as he could tell. Since the onset of symptoms he had lost about half a stone in weight and felt rather weaker, but his appetite had remained good and the bowels were regular. He was a total abstainer and gave no history of venereal disease. He was married and had one healthy child. The family history was good. There was no history of malignant disease in the family.

On admission the patient was a healthy-looking, muscular man, of medium height. The abdomen showed an obvious swelling in the left loin. This was found on palpation to be large and oval in shape, with its long axis directed vertically. It was smooth and firm, and rather elastic to the touch. No fluctuation was detected. There was no tenderness on palpation. Its upper limit was lost under the costal margin. The lower pole extended down into the iliac fossa. Internally it reached almost to the middle line and had a smooth rounded border without a notch. On palpating across its full rounded outer border towards the back it was lost under the erector spinæ mass. On percussion the tumour was dull, except for a vertical band of resonance in front, marking the descending colon. There was only slight movement on respiration. The urine was blood red; it had a specific gravity of 1015. It was acid and contained some amount of albumin. There was a deposit of red and white corpuscles with some large oval cells that might have been epithelial or sarcomatous. A diagnosis of renal growth, probably sarcoma, was made and it was decided to attempt nephrectomy.

Operation was performed on Feb. 17th, by Professor Wright, chloroform being administered by Dr. W. J. S. Bythell. A large lumbar incision through the thick abdominal muscles showed that the tumour was fluctuant, and in the attempt to draw it up into the wound a hole was torn in the cortex, through which gushed a good quart of port-wine coloured fluid. After this the hydronephrotic kidney could be delivered readily. It was a large unilocular sac containing a solid growth on its inner aspect in the region from which the ureter ran downwards. The ureter and vessels were clamped and the upper pole was freed. On attempting to free the lower pole the hydronephrotic sac was found to give place to normal kidney substance. The kidney was abnormally elongated, and could be traced downwards and then inwards across the middle line a short distance above the sacral promontory. No right kidney could be palpated through the incision (though its absence could not be definitely ascertained), nor could a second ureter be felt below. Since it had every appearance of a single horse-shoe kidney, no further attempt was made to free the lower pole, but it was cut across at the lower limit of the cystic portion. The left ureter and renal vessels were now ligatured and divided and the cyst removed. The cut surface of the normal kidney substance remaining was sutured into the incision for drainage purposes, as was the upper end of the ureter. The large cavity remaining was then flushed out with weak biniodide of mercury lotion and normal saline solution and the wound was closed with silkworm gut. A large drainage-tube was left in. The shock of the operation was considerable. On the following morning 10 ounces of blood-stained urine were obtained from the bladder by catheter, after which he passed on successive days 14 ounces, 32½ ounces, and 34 ounces of clear urine, containing on an average 1·5 per cent. of urea, besides a considerable amount that escaped into the dressings from the divided kidney. On the second day he began to suffer from violent and distressing hiccough that was not relieved by sedatives. Propping him upright in a chair gave partial relief, but he could not bear this position long. On the fifth day the pulse and urine began to fail, and on the morning of the sixth day he died.

Necropsy.—The diagnosis of horse-shoe kidney was confirmed. There was no kidney in the right renal fossa. The portion of the single kidney left at the operation was found to extend across the middle line at the level of the fifth

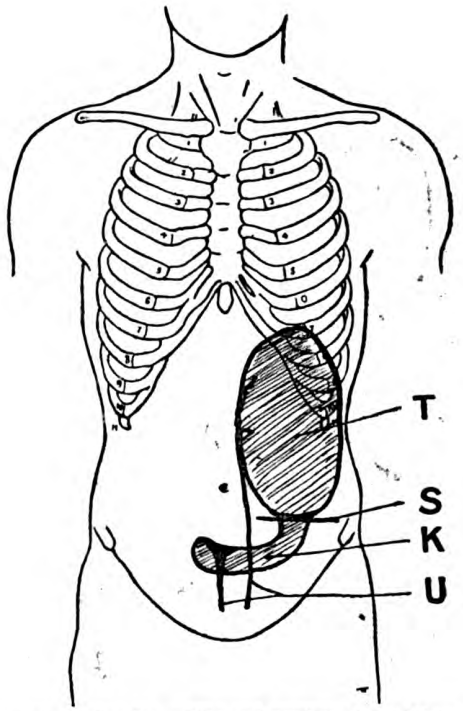

Diagram showing the outline and position of the kidney. T, Tumour. S, Point of section. K, Normal kidney substance. U, Ureters.

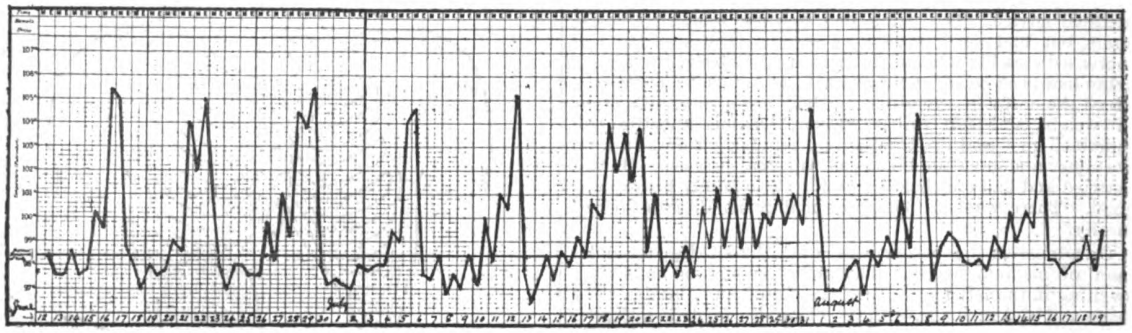
lumbar vertebra, reaching over one inch to the right of the middle line, and from its concave upper margin the right ureter ran down across the anterior surface of the kidney to enter the pelvis. The part of the organ removed at the operation was of about the size and shape of a cocoanut shell. It showed a single large cavity, smooth internally, with but little trace of subdivision into lobules. The cortex was half a centimetre thick, tough and fibrous, and microscopic sections through it showed only fibrous tissue, except at the lower part, where kidney tubules were present. Inside the cyst on its ureteric aspect was situated a sessile, papillomatous growth fungating into the cyst. It was remarkably like a papilliferous ovarian cyst in appearance. The main growth consisted of pale pink nodules, as it were heaped together, and the surface was everywhere lobulated finely like a raspberry. Scattered all round this on the cyst wall were isolated nodules of the same pink raspberry-like appearance. The growth completely filled the pelvis of the kidney, and it was only with difficulty that a probe could be passed up from the ureter through it. Microscopical sections showed a typical papillomatous

growth consisting of several layers of tall columnar epithelium on a delicate connective-tissue stroma. There was no infiltration of the subjacent wall of the hydronephrotic sac.



Remarks by Professor WRIGHT.—I will only add to Dr. Morley's report that the combination of papilloma with hydronephrosis in a horse-shoe kidney has not, so far as I have ascertained, been previously recorded. It is, I think, only the second or third horse-shoe kidney I have met with during an operation, and one has little ground to go upon in deciding upon the risk of interference in such cases. The evidence of cystoscopy and radioscopy might or might not be of value.

Manchester.

RAT-BITE FEVER.

BY GEORGE S. MIDDLETON, M.D. GLASG.,
PHYSICIAN TO THE ROYAL INFIRMARY, GLASGOW.

THE January issue of the *Quarterly Journal of Medicine* contains an interesting paper by Dr. T. J. Horder on three cases of irregularly periodic fever associated with the bite of a rat, and so alike in their other features as to cause him to group them together under the name of "rat-bite fever." To his case I wish to add another which was under my observation in the Glasgow Royal Infirmary many years ago.

A female, aged 3 years, was admitted to a surgical ward of the Royal Infirmary on June 12th, 1895, with the story that while asleep in bed she had been bitten by a rat on the back of the left hand, that the wound had healed readily, but that a fortnight later the hand and arm had begun to swell and had become red and painful, and that a lump had appeared in the left axilla. The child was reported to have had feverish attacks, each lasting about 48 hours, with severe sweating and prostration, but no complaint of pain. Before each feverish paroxysm the hand and arm were said to present swelling, so that the father knew when to expect an attack. Between the attacks there had generally been two or three days of apyrexia.

On admission the dorsum of the left hand was a little swollen and presented two or three small cicatrices, which her father (a gamekeeper) stated were due to dog-bites. In the left axilla there was a small but enlarged superficial lymphatic gland, the skin over which was a little red but not tender. While in the surgical ward she had an attack of fever lasting from June 15th to 17th, with a maximum temperature of 105·4° F. She was transferred to my ward on the 21st and remained in it until August 20th, and during that time she had eight attacks of fever. These were not preceded by any marked swelling of the hand or arm. Their duration was variable, but never less than two days. In some the onset was slow, in others quite abrupt. The temperature always rose to 104° or 105°. A few enlarged glands were found in both axillæ, but they were not tender. It was thought that there was a little dulness at the base of the left lung, but it was indefinite. During the third febrile attack there was observed a red, patchy, measly rash on the cheeks, forehead, and legs, but scarcely at all on the trunk. A rash of similar character, but generally involving the trunk also, was met with in almost every subsequent febrile attack.

During the whole period of the child's residence in hospital there was nothing discovered in the lungs or in any of the other organs to account for the pyrexial attacks indicated upon the accompanying chart. The liver and the spleen did not seem to be enlarged. Only on one occasion was tenderness noted in any of the lymphatic glands. Treatment consisted in the administration of one grain of quinine every three or four hours. The child was taken home in August, and thereafter had several febrile attacks. She was under observation for a week in January, 1896, and was then quite well.

The examination of the blood was kindly undertaken for me by my friend, Dr. W. K. Hunter, who has given me the following report: "During the month of July the blood was repeatedly examined, both in fresh and in stained films. There was a slight leucocytosis and many of the leucocytes contained an undue amount of black pigment granules. In fresh specimens several of the red corpuscles were seen to contain one or more rod-shaped bodies which showed a certain amount of movement, but these were not visible in stained preparations, and their nature was not determined. In one fresh film there was discovered a diplococcus which seemed to have a capsule. Cultures made from the blood in several different media gave a growth only in one tube—namely, in an anaerobic gelatin tube. This growth had a reddish colour, and on microscopic examination was found to be a diplococcus without capsule. This micro-organism was not familiar to me nor to any of the staff in the bacteriological department of the infirmary. The pathogenic properties of the organism were not investigated."

Glasgow.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A FATAL CASE OF GASTRIC TETANY.

BY GEORGE A. GORDON, M.D. EDIN.

THIS condition is, I think, sufficiently uncommon to warrant the following case, which came under my care recently, being recorded.

At 9.30 one morning I was summoned to a woman who I was informed had had a fit. I had not seen the patient previously, and on arrival found the woman perfectly conscious. She told me her age was 48, and that she had suffered for many years from indigestion, vomiting nearly everything she took to eat. She had never had medical advice, fearing that the medical man would make her take to her bed, which she could not afford to do. On examination I found both arms flexed at the elbows and wrists, the arms being folded over the chest. The fingers were bent at the metacarpo-phalangeal joints and extended at the terminal ones. The lower extremities were perfectly rigid, with the toes flexed. It needed considerable force to straighten the arms or bend the legs. The stomach was greatly dilated and I suspected the presence of a small mass in the region of the pylorus. Of this I could not be certain, as the abdominal muscles were fairly rigid.

I administered 30 grains of potassium bromide and 15 grains of chloral hydrate, but on returning an hour

later found that the draught had had no effect. The patient was now becoming cyanosed and was slightly delirious. Chloroform was then given, and when deeply under its control the limbs became only slightly less rigid. On recovering from the effects of the chloroform the woman seemed better and talked more rationally. In a short time, however, she relapsed into delirium. She became unconscious about 12 o'clock and died at 1.15.

As far as I could find out this was the first attack of the kind the patient had had. On the morning in question a neighbour, hearing screams and suspecting that something was the matter, went in and found the woman lying in bed unconscious and quite stiff. There seems no doubt that this was a true case of tetany and that the patient's life could have been greatly prolonged had she sought advice from a medical man at an earlier date.

Richmond, S.W.

NOTES ON AN INTERESTING CASE OF TRIPLETS.

BY GEORGE ALDRIDGE, L.M.S.S.A. LOND.,
MEDICAL OFFICER OF HEALTH, SHEERNESS-ON-SEA.

THE retention of dead twin fœtuses until a third fœtus had reached to nearly nine months' development is, I think, sufficiently rare to warrant publication.

On Whit-Monday I was called to attend a case of labour—a primipara, aged 28 years. On examining I found presenting outside the vulva the foot and leg of a fœtus. This I was able to deliver quickly and easily, and found it to be a male mummified fœtus of about six months' development. On further examination I felt a bag of membranes bulging at the os uteri and the head of a child presenting. The os being fully dilated I ruptured the membranes and in about an hour delivered the patient of a living female child of about 8½ months' development. I then placed my hand upon the abdomen to express placenta, and after waiting some time with no result I again examined the patient. The uterus had contracted firmly, but I could feel through the os the foot protruding of another fœtus. This was gripped by the contracted uterus, and the patient, although uneasy, was having no pain. After waiting an hour I examined again and found the os uteri dilating and the leg as well as the foot of a fœtus presenting. Gentle traction seemed to bring on pains, and in about 20 minutes I had delivered the woman of another fœtus (male, mummified) of about four months' development. The placentæ were removed with difficulty. The two male fœtuses were attached to one placenta, whilst the living female child had a separate one. This was apparently a case of two ova, one of them double.

Sheerness.

NOTES ON TWO CASES OF IMPERFORATE HYMEN IN SISTERS.

BY W. BOXER MAYNE, M.R.C.S. ENG., L.R.C.P. LOND.

THE occurrence of this variety of defective development in two sisters is perhaps of some little general gynæcological interest.

The first case was a girl, aged 19 years. Her mother had noticed that for some time she had walked in a somewhat peculiar manner, and being aware that the menstrual flow had never made its appearance sought medical advice. The girl informed me that for several months she had suffered from aching pains in the abdomen and had lately noticed "a swelling in the privates." On examination I found present the condition of hæmatocolpos, the uterus being enlarged to the extent of a four months pregnancy, and protruding between the labia a convex bluish swelling of the size of half a billiard ball. This vaginal septum was incised, when there drained away a large quantity of viscid, almost meconium-like fluid which was unfortunately not measured. A week later the girl was anæsthetised (the incision showing a tendency to somewhat contract) and the fibrous septum wholly broken down; the os was found to be still markedly patulous and œdematous.

The second girl was 16 years of age, whom, having never menstruated, I was asked to see as well on this account. The hymen was found to be absolutely imperforate; this was incised and freely stretched; no retained menstrual fluid was present.

Swindon.

Medical Societies.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

The Wassermann Reaction in Eye-work.—Acute Hæmorrhagic Pancreatitis.

A MEETING of this society was held on June 3rd, Mr. W. MCADAM ECCLES being in the chair.

Mr. N. BISHOP HARMAN read a paper on Some Recent Experiences of the Wassermann Reaction in Eye-work. The work covered a series of some 40 cases seen in the out-patient department of the West London Hospital. The pathological examination of the blood by this method was performed by Dr. E. H. Blunt, working under the supervision of Dr. J. M. Bernstein, pathologist to the hospital. After a brief discussion of the principles underlying the reaction and a note of the technique adopted, the features of the cases were described. They formed three groups: 1. Children suffering from acute interstitial keratitis of a type that left no reasonable doubt that the inheritance of syphilis was the primary factor; in each case the Wassermann reaction proved positive. Further, the mothers of these children were simultaneously examined in the same fashion, and in each case the reaction was positive. Such a result indicates that although the mothers show no sign of syphilis yet they are as profoundly affected by the syphilitic poison as their marked offspring. 2. Twelve cases of ocular disease past or present in adults. The conditions ranged from scars of interstitial keratitis long passed to recent optic atrophy with ocular paralyses. Again, in each of these cases of presumed syphilitic origin the serum reaction proved positive. 3. The last group of 10 cases covered a varied selection of inflammations as nearly similar as possible to those found in the syphilitic groups, and yet in which there was no suspicion of a syphilitic origin; the subjects were equally divided between children and adults. In this series of cases the serum reaction, taken under exactly identical conditions as the foregoing, proved negative. In conclusion, Mr. Bishop Harman considered that these results added to the cumulative evidence of the reliability of the Wassermann reaction, and he instanced as one of its commendable features the fact that it entailed no risks to the patient and no inconvenience other than the abstraction of a few drops of blood. When the test had been standardised, as the pathologists now proposed to do, its value would be increased, for it would not only indicate a general syphilitic infection, but also point to the particular nature of a given local inflammation.—Mr. MCADAM ECCLES suggested testing the father and apparently healthy brothers and sisters of the patient, and he raised the question as to whether it might not be worth while to treat an apparently healthy child with antisyphilitic remedies in view of the treatment of interstitial keratitis being so prolonged.—Mr. J. E. R. MCDONAGH mentioned two cases of interstitial keratitis recently under his care. One was a girl who first showed the disease at the age of 23 years, and gave a positive Wassermann reaction. The second case was a married woman with one child. She had had double interstitial keratitis and had Hutchinsonian teeth; both mother and child gave a positive reaction. He recommended that all children of a suspected mother should be tested, and those giving a positive reaction treated with antisyphilitic remedies. He mentioned the work done in animals as to syphilitic interstitial keratitis, and that the spirochæta pallida had been found in the cornea.

Dr. A. ELLIOT read a paper on Acute Hæmorrhagic Pancreatitis. The conditions presented by two cases of the disease were detailed in full. Both occurred in men between 40 and 50 years of age, who were considerably over the average weight for their age and height, and who habitually took alcohol in considerable quantity. In both the onset was sudden, and in both the chief symptom was intense epigastric pain with vomiting. In one case laparotomy was performed; the other was not operated on. Both cases ended fatally, one in 26 hours and the other in 48 hours. The etiology of the disease was discussed. It was pointed out that the disease is most prone to occur in adult males, though not confined to men or adult life. Persons of abundant adipose tissue and alcoholic habits are the most

frequent sufferers. The relation of cholelithiasis with pancreatic inflammation was traced, and the relative parts played by inflammation and hæmorrhage discussed. As to diagnosis, it was suggested that the suddenness of onset, the extreme severity of the pain, and the persistence and urgency of the vomiting formed a symptom-complex more frequently found in this malady than in the other acute emergencies in the upper abdomen; that there was but little tenderness to palpation in the early stages, and that the collapse to which various writers have attached much importance did not occur in Dr. Elliot's cases until a late period of the disease. The pancreatic urinary reaction of Dr. P. J. Cammidge and the presence of fat necrosis were shown to be of value in the later stages. The acute abdominal conditions for which pancreatic inflammation might be mistaken were enumerated and the differential diagnosis discussed. The paper closed with an appeal for early surgical measures in all cases in which acute hæmorrhagic pancreatitis was diagnosed or deemed to be the most likely explanation of the symptoms.—Mr. MCADAM ECCLES said that he considered drainage through the lesser omentum and free drainage of the biliary passages gave the only hope if done in the early stages of the disease.—Dr. G. C. LOW described four post-mortem examinations on this condition which he had performed whilst doing the pathological work at the West London Hospital. He described the naked-eye and microscopical appearances of fat necrosis, and drew attention to its being found only in the abdominal cavity, not, for instance, in the subcutaneous fat of the abdominal wall or within the thorax. He also mentioned a case of malarial hæmorrhagic pancreatitis; in this case there were no areas of fat necrosis.—Dr. J. A. CAIRNS FORSYTH had seen six cases of acute hæmorrhagic pancreatitis operated on. Only one was successful. He was inclined to think that many of the cases were non-inflammatory at the commencement—in fact, an apoplexy of the gland. He pointed out that they were generally cases in which hæmorrhage might occur in other tissues. He thought that a gauze drain might be placed in the foramen of Winslow if patent, as well as drainage of the lesser sac and bile passages.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

Insanity as Disorder of Conduct.—Examination of Cerebro-spinal Fluid.—The Toxic and Exhaustion Psychoses.

THE general quarterly meeting of this association was held at the rooms of the Medical Society of London, Chandos-street, W., on May 24th, under the presidency of Professor W. LEWIS.

Before entering upon the business of the meeting the PRESIDENT referred in eloquent and touching terms to the recent death of his late Majesty King Edward VII., by which the nation had sustained a great calamity. The passing away of his princely spirit was an irreparable loss, and the medical profession felt that loss as keenly as any. The meeting rose and passed in silence a resolution to memorialise King George V. and the Queen-Mother on the sad event.

After the formal business had been transacted, Dr. CHARLES MERCIER read a paper on Insanity as Disorder of Conduct. He said that he was surprised to find at a recent meeting of a committee of the association that he found not a single supporter for his suggestion that [illegible] of conduct should form an item in the proposed [illegible] of the subjects for a diploma in psychiatry. He had [illegible] that the doctrine that insanity and disorder of the [illegible] were convertible terms had been exploded 25 years ago. [illegible] ceeded to instance cases of claustrophobia, and [illegible] as disorders of mind that are not insanity, [illegible] of insanity in which disorder of mind was irrel[illegible] In one case, on being introduced to a lady, she spat [illegible]. He sat down at once and certified her to be insa[illegible] interchanging a word with her. He knew noth[illegible] the state of her mind, nor did it interest him. If the [illegible] condition of a patient was given in a certificate of [illegible] certificate did not give facts observed, for [illegible] condition could not be observed; it could only [illegible] from conduct. Nor is the mental state importan[illegible] as suggesting tendencies in conduct. Since in ev[illegible] we have to infer mind from conduct, and then infer back again from mind to conduct, why not simplify the operation and look to conduct as of primary importance? The syllabus stated that it was important for the student of insanity to test the patient's reaction-time, to discover his æsthetic sentiments, to examine his estimation of time and space, to know his response to the ergograph; but whether he was suicidal or dangerous, whether he could earn his living, whether he tore up his clothes or was indecent, whether he tried to murder his wife and children—all these were matters of profound indifference to the alienist. That was the lesson to be learnt from the syllabus; that is what students are taught by it. He submitted that conduct was all-important in insanity, that it ought to be studied, and ought to be studied systematically.—Dr. G. H. SAVAGE said that certain certificates which he had signed had been wide of the mark concerning facts as observed by himself. A lady might have her powers of calculation and reasoning intact, but if she left home and did many strange things indicating a tendency to lust, one would recognise symptoms indicating insanity. Because a man lost a certain kind of memory he should not be regarded as insane; a man might be very mad and yet be right in his conduct. Even the committal of a crime did not in itself constitute insanity. Some teachers were always insisting on the danger of the definite, and certainly one must not be governed by definitions which were too rigid. He was much indebted to Dr. Mercier for insisting that insanity must be looked at from the practical rather than the purely scientific point of view.—Dr. W. H. B. STODDART said the point at which he parted company from Dr. Mercier was that he (Dr. Stoddart) regarded conduct as a part of mind. The difficulty was that a line had to be drawn between conduct and what Dr. Mercier called mind. Conduct appeared to be something muscular; but he did not think one could stop at the muscles and exclude the nervous system or the skull's contents. It would not be easy to say where one's study of conduct was to leave off and the study of psychology to begin.—Dr. R. H. STEEN remarked that Dr. Mercier said when conduct was disordered there was disorder of mind, and he (Dr. Steen) wished to know whether the converse was true. He instanced the case of a girl against whom no disorder of conduct could be alleged, yet who was certified as a private patient, and at the end of a year the certificate was renewed. What was the superintendent of an institution to do with such a case?—Dr. T. DRAPES said he thought Dr. Mercier's remarks would have been apt if he had used the word "certifiable" before "insanity." One was taught that the mind consisted of three departments, intellect, emotion, and will, and that insanity might show itself by disorder of any of these, or of all three together. If Dr. Mercier's views were fully carried out, the occupation of the alienist would be gone, because the man in the street would be regarded as good a judge as the skilled alienist as to whether a man was or was not sane. But the alienist was required to give some explanation of the man's conduct, and that could only be done by a reference to the man's condition.—Dr. A. R. URQUHART complained that the paper just read was not that of the physician, because it did not reflect the physician's point of view. If insanity was merely a disorder of conduct, then the question was rather a legal than a medical one, though, of course, the alienist had to address himself to legal as well as medical matters. Insanity he regarded as a disease of the brain which affected the actions of the body, and the alienist had to inquire what was the reason of the disorder of mind, and what could be done to restore the mind to the normal condition.—Dr. J. F. DIXON asked whether Dr. Mercier wished insanity to be regarded merely as a disorder of conduct without any reference to the supposed state of mind which led up to that disordered conduct. If insanity was merely disordered conduct, how could accommodation be provided in this country for all the cases of insanity?—Dr. BEDFORD PIERCE said he understood the thesis to be that there was no insanity without disorder of conduct. If that were so, there was no knowledge of insanity without disordered conduct. How did Dr. Mercier speak of the person troubled with obsessions to murder? A man came under his charge voluntarily because he wanted to be protected against himself, as he had an obsession that he would murder his children. His conduct in seeking such protection, however, was not insane.—Dr. R. L. LANGDON-DOWN asked whether one could wholly infer the mental condition from the conduct. Conduct was the text

by which the mind was read, and the text needed to be carefully studied so as to know the state of the mind.—Dr. H. RAYNER narrated a case in which a surgeon did a very strange act to himself, and in which a certificate of insanity was not signed as the alienists concerned did not think there was a likelihood of his doing a similar thing again.—The PRESIDENT said he understood Dr. Mercier to controvert the legal fiction that delusion was a necessary proof of insanity. He (the President) agreed that conduct should be very widely taken into consideration, but a stumbling-block was provided by the problem as to how to deal with crime. It would be difficult to solve in the courts the problem as to what disordered conduct constituted crime.—Dr. MERCIER replied on the discussion, insisting that he was pleading for a systematic study of conduct. He had all along taken the view that every man had an unescapable responsibility for his own acts; and he had never regarded crime and insanity as convertible terms. In answer to Dr. Bedford Pierce's difficult question he would say, look at the man's conduct and ascertain what he did. The man referred to did the most sane thing he could—namely, put himself under Dr. Pierce's care. He (Dr. Mercier) strongly repudiated the notion that mind was to be neglected altogether; but hitherto mind had been too exclusively studied, and conduct had been left out.

Dr. JOHN TURNER read a paper on the Examination of Cerebro-spinal Fluid, with special reference to the diagnostic value of Ross and Jones's test.—Dr. C. HUBERT BOND corroborated the statement as to the ease with which the test was applied, and said he hoped to hear of some equally ready test to show the cases which, at some period of their lives, had had syphilis. The test just described seemed applicable only to syphilis of the nervous system.

Dr. STODDART gave an Enunciation of a Theory of the Toxic and Exhaustion Psychoses. He said the disease to which he referred was also known as post-febrile insanity, acute confusional insanity, and acute hallucinatory insanity, though on the continent the term amentia was preferred. All the cases had the same series of symptoms, and they arose as the result of toxæmias of various kinds, mainly those following acute fevers, though it might occur in those who had undergone profound physical strain, as in one case, that of a man who won a long-distance race. It occurred following mental shock and in those who worked up for examinations. A remarkable symptom was peripheral anæsthesia, often with inability to recognise sounds. Some had apraxia, catalepsy, and katatonia; they also had constant hallucinations in which there was a positive and a negative factor. The peripheral neurons were dissociated, and he believed that dissociation must occur at the synapses, for there was increased synaptic resistance in the whole nervous system.—Dr. HACK TUKE and Dr. BEDFORD PIERCE discusssed the contribution, and Dr. STODDART replied.

POST-GRADUATE MEDICAL WORK, UNIVERSITY OF VIENNA.—For medical men who wish to do post-graduate medical work at the University of Vienna there exist lectures, courses, and practical work. The University lectures are given by the ordinary and extraordinary professors in their institutes and clinics and are held daily for one or two hours during the term, the fees being the same for students and medical men. The courses are held by extraordinary professors, by *privat-docents*, and by assistants, regularly. They generally last four weeks at the rate of one hour per day. They are frequented almost exclusively by medical men and the number of students is generally limited to 10. Practical work is either given in the form of courses, in which the students get the necessary anatomical and clinical material, or for more advanced scholars places can be obtained in the "theoretical" institutes; they can also take part in the practical work at the hospitals as volunteers. For the right of working in the institutes there is generally a moderate laboratory tax to pay, but the volunteers have nothing to pay. The courses, lectures, and practical work take place chiefly at the Wiener Allgemeine Krankenhaus. Certificates of having attended the lectures and courses are obtainable, after certain formalities, from the Dean of the Medical Faculty. Further information may be obtained in a pamphlet written in German, English, and French, and supplied gratis on application to Messrs. Urban and Schwarzenberg, I., Maximilianstrasse, 4, Wien.

Reviews and Notices of Books.

With a Prehistoric People: The Akikúyu of British East Africa. By W. SCORESBY ROUTLEDGE, M.A. Oxon., and KATHERINE ROUTLEDGE, M.A. Trin. Coll. Dub. London: Edward Arnold. 1910. Pp. 392. Price 21s. net.

THE title of this work seems to us meaningless, or at least inaccurate, but the sub-title, "Being some account of the method of life and mode of thought found existent amongst a nation on its first contact with European civilisation," accurately defines the scope of the book. The district in which these people live may be said very roughly to be that lying between long. 34 to 38 East, and lat. 0 to 2 South, and a good deal of it is some 6000 feet above the sea.

In physical characteristics it appears to resemble the Bocage of Vendée, and in the same way as the Vendéens did, the Akikúyu managed to protect themselves from their adversaries. The Republican troops, it will be recollected, were quite at a loss in the labyrinths of the Bocage, and so, too, the Masai found themselves at a terrible disadvantage in the Akikúyu country, where all the trackways were mined with war-pits thoughtfully provided with sharp stakes. Nowadays, however, the Pax Britannica has put an end, more or less, to intertribal fighting, and only the old men remember the fate of enemies trapped in the pits.

Mr. Routledge and his wife have certainly produced a most interesting book, and they are specially to be thanked for one thing, in that they distinguish between what they saw and what they were told. The various sections of the book deal with arts and crafts, social and political life, religion, and folklore. They have only one way of making fire, and that by the friction of two pieces of wood. An unusual feature of this measure is that the piece of wood on, or rather in, which the fire-drill works is laid on a sword, and the hot dust escapes from the fire-stick on to the sword. "The particles forming the pile cohere, but do not smoke or glow. When the mound has attained to the size of a threepenny-piece it is found by experience that a portion of it, the size of half a pea, can be blown up into a solid red-hot ember." The dust is then surrounded by some dry grass, blown upon, and the grass catches fire. The process is curious, and it would almost seem as if the pile of dry grass occluded some gases and possessed the power of becoming hot that is known to be a property of black platinum.

Like all primitive peoples, the Akikúyu live under a most meticulous system of ceremonial and social customs. All the important periods of life have their own complicated etiquette, and Mr. and Mrs. Routledge describe the dances and other customs at length. The initiation ceremonies at puberty are most complicated, and include circumcision for the boys and removal of the nymphæ and clitoris for the girls. There are also special dances before the operation.

Another special dance is that held on the completion of the maize harvest. This dance is performed in the presence of a small clay image in human form, which may be either male or female. Mr. Routledge offers no explanation of this image, but we suggest that it is akin to the kern-baby or mell doll of Europe—that is to say, a representation of the corn spirit. On one point we must differ from Mr. Routledge. He says, as regards an image which he acquired, that it was a female, "the sex being indicated by the small triangular apron which custom amongst the Akikúyu requires even the youngest female child always to wear." We much doubt whether the triangular mark on the image had anything to do with clothing. The triangle is the universal mark in primitive images and drawings for the female sex, and it is obviously a representation of the mons Veneris. Plenty of examples are to be seen in the Babylonian room at the British Museum, where every stage of the device is seen

from the simple incised triangle shown in Case 25, No. 544, up to the more detailed markings shown in the series of Babylonian "Venuses" in Case 35, Nos. 969 *et seq.* Illustrations of similar images will be found in Menant's "Glyptique Orientale," Vol. I., pp. 172–3.

As regards religion, the Akikúyu believe in a Being, N'gai, who lives on Mount Kenia, and their conception of him is of a singularly elevated nature. Mr. Routledge witnessed a solemn sacrifice, followed by the usual communion, to N'gai. The animal chosen was a ram, and contrary to most sacrificial customs where an animal is the victim, it was strangled so that there was no shedding of blood.

The Akikúyu naturally have medicine-men, who, as usual, combine the offices of magician, medical practitioner, prophet, and in some sense priest. The name of a medicine-man is Mun-du-Mu-gu, which literally, according to Mr. A. W. McGregor of the Church Missionary Society, means "a clever man," thus carrying on the idea of knowledge which is apparent in the words "medicine," "medere," "Medea," and the Sanscrit root "madh." We should add, however, that Mr. Routledge says that "this"—i.e., the translation—"scarcely represents the idea conveyed, for the word Mugu is also used in connexion with the tree that is held sacred, Muti Mugu." We know all the same that the ideas of wisdom and healing have ever been closely connected, except among "Christian Scientists"; therefore, to our minds, Mr. McGregor's translation is quite defensible.

The medicine-men are initiated with great ceremony, but according to Mr. Routledge's informants the candidates are elected to their profession by a direct call from God in a vision or dream. This being so, we are not surprised to find that the Akikúyu have a simple method for dealing with heretics without the intervention of a General Medical Council or a Medical Register, for, as Mr. Routledge states with somewhat startling simplicity, "Irregular practitioners are poisoned." Akikúyu medicines are chiefly of the charm order, though remedies are given for gonorrhœa, hæmaturia, and diarrhœa. Surgery is not regarded as part of the medicine-man's function and is apparently simply confined to flesh wounds, which are treated in quite an orthodox manner and do very well.

The Akikúyu wear ornaments in the lobes of their ears, but instead of a simple earring the lobe of the ear is distended to an enormous size, as will be seen in the illustrations to the interesting paper by Mr. Bland-Sutton which appears on p. 1608. Other nations, notably certain South American tribes, have adopted an even odder method of decoration, for they insert cylindrical blocks of wood in their lips. Naturally, the rings into which the ear lobes are converted get torn occasionally and the native surgeons are clever at restoring them. The edges are refreshed and the ends are then joined.

Mr. Routledge and his wife end their book with a series of folk-tales, and they have earned the thanks of all who are interested in out-of-the-way customs and peoples for a carefully written account of a nation whose originality, we presume, is doomed to disappear under contact with civilisation. Mr. Arnold, the publisher, deserves every credit for the printing and the illustrations.

Fisiologia General. Por los Doctores L. RODRIGO LAVIN (Cádiz) y A. PI Y SUÑER (Sevilla). Barcelona: Gustavo Gili. 1909. Pp. 810. Price, paper, 18 pesetas; cloth, 20 pesetas.

THE authors remark that the subject is so vast, even though this work is a treatise on "General Physiology," that collaboration is absolutely necessary, and so it comes that Dr. Lavin is responsible for the chapters on the general physiology of the cell and for the specific physiology of the nervous and secretory cells, while Professor Suñer deals with muscle and the internal media. After a general introduction much like that in other text-books, the work divides itself into three main divisions: (1) the physiology of the cell in general; (2) the physiology of differentiated cells; and (3) the physiology of the internal medium (a term used by Claude Bernard for the blood). This third part deals only with blood and lymph.

The first part occupies about 160 pages and deals with the morphology, chemistry, and physics of living matter—so-called vital phenomena,—metabolism and the exchange of energy, and, lastly, with changes of form. In the morphological part the protozoa come in for a fairly long exposition, the diagrams are bold and clear, and some of them have obviously been redrawn, with modifications, from well-known works. Then follows a general account of absorption and excretion, and the general metabolism of cells, all on the usual lines, including a good account of ferment action. Under exchanges of energy a general account of amœboid, ciliary, and muscular movements is given, and also of those phenomena which are grouped under the term "Tropisms." The last section of Part I., under the term "Cambio de forma," deals with the ovum, reproduction, ovogenesis, spermatogenesis, and heredity. Part II. begins with the neuro-muscular system and leads on to the consideration of reflex acts and to the general physiology of muscle and nerve, in which there is nothing to call for special notice. We are glad to see a figure (Fig. 160) of Marey's experiment on elasticity, to illustrate the importance of the elasticity of muscle. Waller's illustrations on electrical phenomena are freely laid under contribution and acknowledged. Under fatigue of muscle the modification of Mosso's ergograph by Treves is introduced, an apparatus not usually figured in English text-books. A very readable account is given of the general structure of nerve cells under the head of Neurons, as one would naturally expect from the countrymen of Ramon y Cajal. This leads on to the general physiology of nerve. The remainder of the work, about 200 pages, is devoted to the blood and lymph, considered as internal media. Some of the "figured elements" of the blood are well drawn, though no scale is given. Hæmolysins and immunity are dealt with shortly.

It will be seen that this book is a work on "General Physiology" in the most general sense. There is nothing about digestion, respiration, circulation, or the senses. There is only a list of contents and no index, which we think is a mistake. The work may meet in part the requirements of science students in Spain, but it is not suited for students of medicine, being too restricted in its scope.

Manual of Tropical Medicine. By ALDO CASTELLANI, M.D. Florence, Director of the Clinique for Tropical Diseases, Ceylon; and ALBERT J. CHALMERS, M.D. Vict. and Liverp., F.R.C.S. Eng., D.P.H. Camb., Registrar and Lecturer on Pathology and Animal Parasitology, Ceylon Medical College. With 373 illustrations in the text and 14 coloured plates. London: Baillière, Tindall, and Cox. 1910. Pp. 1242. Price 21*s.* net.

THIS volume, which is one of the publishers' "University Series," is dedicated by its authors to Sir Patrick Manson, as the accepted "founder of scientific tropical medicine." The object of the book, as stated in the preface, is to describe the knowledge which the writers found necessary to acquire and use during the course of their work in tropical Africa and Asia. Efforts have been made to keep the matter within as small limits as possible, and for this purpose all references to practical laboratory methods have been omitted. For this part of the subject the reader is referred to the standard text-books. The authors at the outset clearly state their opinion, with which we are in entire agreement, that it is little use for any medical man, however highly qualified he may be in

other respects, to attempt to practise his profession, at any rate nowadays, with any degree of success in the tropics without having first gone through a course of instruction in one or another of the Schools of Tropical Medicine.

The book is divided into three main parts. The first part, which is introductory, includes four chapters which give a short outline of the history of tropical medicine, with some observations on tropical climatology, the effects of tropical climates on man, and on the incidence of disease in the tropics. The second part deals with the causation of disease in the tropics, attention being directed separately to the physical, chemical, and biological causes. Under the physical causes, the pathological effects of high atmospheric temperatures are discussed. Among the chemical causes considered by the authors are tropical intoxications: poisons and poisonous weapons, poisonous foods, and venomous animals. In the 12 chapters, comprising 425 pages, which deal with the important subject of the biological causes of disease, the various kinds of animal and "vegetal" parasites are fully discussed.

About half of the volume is devoted to Part 3, which deals in detail with the diseases of the tropics. The authors adopt a classification which divides these maladies into three sections—viz., fevers, general diseases, and systemic diseases. Among the fevers are included malaria, plague, the kala-azars, the trypanosomiases, dengue, and yellow fever; among the general diseases are classed leprosy, the filariases, frambœsia, beri-beri, epidemic dropsy, and pellagra; while among systemic diseases are placed such varied ailments as ankylostomiasis, cholera, the dysenteries, sprue, and hill diarrhœa, as well as skin diseases. Some special consideration is given to these cutaneous maladies, seven chapters and a large number of illustrations being devoted to them. Classification of tropical diseases is, we admit, by no means an easy task, but we are not altogether sure that the plan adopted by the authors is quite free from objection. Considerable attention has been given to the clinical features of each disease and to treatment, details of which are set out clearly as regards dosage and methods of administration of remedies, on the ground that practitioners working in the tropics have often no opportunity of consulting works on therapeutics and materia medica.

A vast amount of pains and patience must have been required to collect and bring up to date the full and varied information which is presented to the readers of this book. Each chapter is furnished with a list of references to the authorities whose works have been consulted in connexion with the subject. So far as we are able to judge, the knowledge presented in this volume is sound, accurate, and up-to-date. Of course, here and there small points are noticeable in which more recent information has modified opinions, and this is unavoidable in a work on tropical medicine, advances in which are day by day taking place. It is probably for this reason that no mention appears to be made of the theory of the causation of beri-beri by an insufficiency of phosphorus in the diet, a theory which recent work in the Federated Malay States Institute for Medical Research and elsewhere seems to have placed on a solid basis. In the authors' view it is more probable that the actual cause will be found to be a protozoon than that it is due to diet. Some of the terms employed in this volume may be strictly correct, but they differ from those more commonly used by other eminent writers on tropical medicine. For example, it may perhaps be considered by some a trifle pedantic to write "agchylostoma" instead of ankylostoma, to which we have been so long accustomed.

This "Manual of Tropical Medicine" is a work which must in our opinion prove of great service to all who are practising, or intend to practise, their profession in the tropics, and we therefore, with entire confidence, recommend it for the purpose. The practical experience of the authors in this branch of knowledge lends additional weight to the views which they so well put forward. The book may be regarded as a small library in itself. Appended to the volume is a very full index, not only of subjects but also of authorities; this will greatly facilitate rapid reference to any disease concerning which information in respect of diagnosis, prophylaxis, or treatment may be desired by the practitioner in the tropics.

A Manual of Midwifery. By HENRY JELLETT, B.A., M.D. Dub., F.R.C.P. Irel., L.M., King's Professor of Midwifery in the School of Physic, Trinity College, Dublin; Gynæcologist to Sir Patrick Dun's Hospital; President of Obstetrical Section of the Royal Academy of Medicine in Ireland. With the assistance of W. R. DAWSON, M.D. Dub., F.R.C.P. Irel., Medical Superintendent, Farnham House, Dublin; H. C. DRURY, M.D. Dub., F.R.C.P. Irel., Physician to Sir Patrick Dun's Hospital; T. G. MOORHEAD, M.D. Dub., F.R.C.P. Irel., Physician to the Royal City of Dublin Hospital; and R. J. ROWLETTE, M.D. Dub., Pathologist to the Rotunda Hospital. Second edition. With 557 illustrations and 17 plates. London: Baillière, Tindall, and Cox. 1910. Pp. xiv.-1210. Price 21*s.* net.

IN the second edition of his "Manual," already so favourably known both to students and their teachers, Dr. Henry Jellett has inserted a new set of illustrations in the section on Obstetrical Anatomy and has also revised the text, more especially that dealing with the formation of the embryo. The emendations are distinctly for the better. We think the author does not lay enough stress upon the fact that the formation of the amnion in the human ovum does not follow the same lines as that in some of the other mammalia, and the possibility of the student not realising this, although it is stated in the text, may be increased by the introduction of Fig. 56, which probably does not represent the conditions obtaining in man. In the same way it would have been better if it had been stated that Fig. 61 refers to the ovum of the guinea-pig, but upon both points the student may expect to obtain guidance from his lecturers.

A new series of figures has also been added to illustrate the mechanism of labour. Some of these are very good but some of them do not appear to us to be wholly satisfactory. For example, we do not consider that either Fig. 181 or Fig. 217 represents truly what can be felt by the vagina in the four positions of the vertex or of the face, and indeed the former does not correspond to Figs. 185 and 186, which show the head in the same position. In the description of the mechanism of labour we find no mention of the fact that in all probability the so-called movement of flexion is of little importance, and probably should not be described as an integral part of the mechanism of labour and placed on an equality with the movement of internal rotation. Every frozen section of the first or second stage of labour, with the exception of that of Pinard and Varnier, which relates to a case of occipito-posterior presentation, shows the head with the chin on the sternum—that is, in a position of complete flexion. It is very doubtful, therefore, whether this movement takes place at all in a case of normal labour, and in a modern text-book we would have expected to find some mention of this fact, and we should not expect to find such a statement as the following without any qualification—viz., that during the mechanism of labour "the occiput is driven down until the chin comes into contact with the sternum." Further, in describing the causation of the movement of internal rotation, the author lays stress upon the action of the helical shape of the internal surface of the ischium, a factor which plays but a very unimportant part, if any, in the case of a normal pelvis. There is also no

mention of the view, supported by Schroeder and Olshausen, that the internal rotation of the head is initiated by the rotation of the body, nor is there any of the recent most important work of Sellheim, who maintains that internal rotation is the result of a definite physical law.

In a manual intended for students who are only too ready to follow new methods of treatment, often to the exclusion of old and better known ones, it was inadvisable to include a description of King's postural method of correcting transverse presentations, more especially as the author admits that he has no personal experience of this procedure.

The pathological anatomy of vesicular mole and of chorion epithelioma has been revised well by Dr. R. J. Rowlette. The three subjects of acute yellow atrophy, hyperemesis gravidarum, and eclampsia have been included in one chapter under the heading of the Toxæmias of Pregnancy; although, as Dr. Jellett points out, this does not imply that he is ready to adopt the view that all these conditions are only different phases of a specific toxæmia. In the treatment of eclampsia the important question as to operative interference is answered in the following way: the general practitioner is recommended to carry out expectant treatment as far as possible, but in view of the good results which have been obtained by its use the expert is advised to resort to the use of Bossi's dilator and to deliver the patient as soon as possible after the convulsions have begun. This appears to us to be sagacious advice in both directions.

A very good account has been added of vaginal Cæsarean section and a very fair one on pubiotomy. We cannot agree in the treatment of asphyxia neonatorum that Marshall Hall's method of artificial respiration is of any value; indeed, Champneys has clearly shown that in these cases it is markedly inferior to that of Silvester.

The great majority of the illustrations in the book are good, but we hope that in a new edition those illustrating the section on monsters may be redrawn, as they are poor and certainly not artistic.

We have been critical on many details in the work of Dr. Jellett and his collaborators because the work is a valuable and authoritative one demanding to be tried by a high standard. They have produced a good text-book, and as it represents the teaching of the Dublin school it has special interest for English readers. It is probable that the second edition will achieve as marked a success as the first, when the points to which we have drawn attention can easily be dealt with.

Die Vergiftungen. Von Dr. R. v. JAKSCH, o. ö. Prof. der Speziellen Medizinischen Pathologie und Therapie, Universität Prag. Zweite, vollständig umgearbeitete und vermehrte Auflage. Mit 42 Abbildungen. Wien und Leipzig: Verlag von Alfred Hölder. 1910. Pp. 732. Price, paper, M.16.

THIS is the second edition of a work which has always been looked upon as being among the leading works on poisons. The first 600 pages deal with the exogenous poisons, a very full description being given of the symptoms, pathology, diagnosis, and treatment in regard to every known vegetable and animal product which can give rise to toxæmia. A chapter is devoted to plant poisons which produce symptoms analogous to those which are commonly known to occur with certain primulas, and contains a good deal that is new and interesting.

Although the value of the chapters on the mineral and metallic poisons is much enhanced by cases which have been under the author's care and by a fuller description of the pathology, nothing new has been added, and the treatment remains the same to-day as that which was in vogue years ago. Several cases are cited of poisoning from drugs and chemicals very rarely used, but it is the mention of these which makes the book complete and so valuable for reference.

The chief feature of the new edition is the inclusion of a chapter on the effects of poisons, or endogenous toxins, caused by malignant growths and the various infective fevers. Besides the pathological conditions which can give rise to symptoms of intoxication, such intoxications can also be caused by the normal products of metabolism. In discussing the etiology of these conditions we are struck by the absence of any mention being made of anaphylaxia. This is all the more noteworthy since not only has very much attention of late been paid to this phenomenon, but also in our opinion it helps to explain the idiosyncrasies shown by different people to various drugs and articles of food; and not a word has been mentioned of the "serum disease," a disease which should always be borne in mind in this age of serotherapeutics. Certain poisoning effects of almost daily occurrence are undoubtedly due to various toxins, probably of a protein nature, which so act on the vaso-motor centre as to cause the various symptoms of vaso-constrictor paralysis—namely, urticaria, angioneurotic œdema, strophulus, and the like. The author very rightly points out how unavailing treatment is in general, and how very unlikely we are to get any better results until our knowledge has so far advanced as to be able to tell the chemical nature of the various toxins produced.

A more thorough study than has heretofore been attempted is contained in the description of the effects produced by the various plant and animal poisons. Especially interesting is the chapter on the toxins produced by photodynamic substances, since attention has been of late so much directed to the severe lesions resulting from the X rays. In the author's opinion some people show a marked idiosyncrasy to the X rays, the smallest dose being capable of producing an erythema, pigmentation, or even herpes zoster. Stress is laid upon the fact that a transient erythema may be followed, weeks or even months later, without a further application of the rays, by ulceration, showing that a toxin is produced which may remain latent for some considerable time. Since such can occur the greatest care must be taken in giving subsequent doses. Some interesting experiments are included which go to show that the X rays have a decided destructive action on the leucocytes without in any way affecting the red blood corpuscles, which would account for the improvement seen in cases of leukæmia treated with the X rays. The author observed that the skin of the back of leukæmic patients showed a marked predilection to injury by the rays, and that owing to the large dosage which these patients required ulceration was not uncommon. The difficulty was overcome by the insertion of a silver plate into the tube, which enabled an animal to be exposed to the rays for 18 hours without any untoward effect resulting, while a control animal succumbed from ulceration in a few weeks. In the treatment of X ray burns the permanent water-bath proved to be the most efficacious.

Full attention has been paid to the pathological changes produced by the various poisons, which must prove of great value to the medico-legal student. A good index is also appended. We can strongly recommend this book to every medical man, whatever his bent may be, as it will form an excellent work of reference upon a subject the literature of which is not voluminous.

LIBRARY TABLE.

The History of St. George's Hospital. By GEORGE C. PEACHEY. London: John Bale, Sons, and Danielsson, Limited. Part I. Price 2*s.* 6*d.* net.—For some years past the compilation of the history of St. George's Hospital has been in progress, and the first of the 12 parts comprised by the

work has now been issued. The history, we are told by the publishers, is treated in four sections as follows: (1) The first 20 years, 1733–53, which will contain a critical *résumé* of the origin and evolution of hospitals and medical schools in England; (2) St. George's as it was in the time of John Hunter, 1756–1793; (3) St. George's as it was in the time of Baillie, Young, and Brodie, 1793–1840; (4) St. George's as it was in the Victorian era, 1840–1900. The first part contains an epitome of the provision made for the sick poor in England from early times to the foundation of the Westminster Infirmary in 1719; together with a detailed account of the secession from Westminster to Hyde Park Corner in 1733. The second part will deal with Lanesborough House and its surroundings at the date of its transformation into St. George's Hospital, with contemporary illustrations; and subsequent parts will treat of the general management of the hospital, the medical, surgical and nursing staff, medical education, &c. Each part will consist of about 50 pages, crown quarto, with marginal- and foot-notes and illustrations. An index of contents will be issued upon the completion of the work, copies of which may be obtained by application to the author, Mr. George C. Peachey, 11A, Oxford and Cambridge-mansions, London, N.W. Part I. tells of the early guilds, the monasteries, the chantries, the leper hospitals, and the charitable foundations. Then came Sir Richard Gresham, the Lord Mayor of London, who petitioned King Henry VIII., with the result that in 1553 the five Royal hospitals of St. Bartholomew, Christ, St. Thomas, Bethlehem, and Bridewell came under the power of the Lord Mayor and commonalty of the City of London, who were incorporated by charter as perpetual governors of them. The measures taken during Elizabeth's reign are detailed; then there is a jump to the year 1714, when the proposals of John Beller, a Quaker philanthropist, are discussed. In 1715 the Westminster Infirmary is noticed under the heading of the Westminster Charitable Society, which in 1719 took premises in Petty France, but in 1724 was moved to Chapel-street, Westminster, and in 1733 found occasion to vacate those premises as they were still too small, and it was then (Oct. 19th, 1733) that there was a secession of the minority of the medical staff. This group of physicians preferred the higher part of Westminster to the lower and formed themselves into a new regular society and migrated to Hyde Park Corner to the premises leased to them by Mr. Lane called Lanesborough House, where the general meeting of the new society was held for the first time on Nov. 2nd, 1733. There was printed "An Account of the Occasion and Manner of Erecting a Hospital at Lanesborough House, near Hyde Park Corner. Published by order of the General Board of Governors there, Wednesday, Feb. the 6th, 1733." It was ordered that 1500 copies of this account should be printed, none of which has come to light, the copy of the account now printed in the present history being transcribed from the minutes of the Westminster Infirmary. Some critical remarks upon this account were published by a Westminster subscriber, enabling the merits of each side to be judged even now. This was the beginning of St. George's Hospital, Hyde Park Corner, Westminster, and it is all set out in interesting detail in the first part of Mr. Peachey's book. The compilation has obviously entailed upon him much research among public records and private muniments, and he may well command the support of St. George's men past and present, as also of those generally who take an interest in hospital affairs.

The Transactions of the Edinburgh Obstetrical Society. Vol. XXXIV. Session 1908–09. Edinburgh: Oliver and Boyd. 1909. Pp. 383.—The Transactions of the Edinburgh Obstetrical Society for the session 1908–09 contain a number of excellent papers. The Presidential address was given by Professor W. Stephenson, who took for his subject "Our Four Forefathers in Midwifery," and gave an interesting account of the work of Smellie, William Hunter, Denman, and Burns. Among the more important of the papers relating to obstetrical subjects which were read during the year were the following: Prematernity Hospital Practice, a series of 30 cases of morbid pregnancy treated in the Royal Maternity Hospital during the autumn quarter, 1908, by Dr. J. W. Ballantyne; Renal Decapsulation in Puerperal Eclampsia, and a Short Experience of Scopolamine-Morphine Narcosis in Labour, by Sir J. Halliday Croom; the Anatomy and Histology of the Pregnant Tube, by Dr. James Young; A Plea for a Rational Puerperium, by Dr. F. W. N. Haultain; and a paper on the Value of Manipulative Action Combined with Axis Traction in the Use of the Forceps, by the President. Among the more important of the papers relating to gynæcology is one on the Physiological Conditions Relative to the Conservative Surgery of the Uterus, Tubes, and Ovaries, by Mr. E. W. Scott Carmichael, and a paper on the Complications and Difficulties in a Series of 250 Ovariotomies, by Dr. J. Munro Kerr. A series of interesting papers, all from the pen of Dr. D. Berry Hart, include the following: The Interpretation of the Porro Uterus in Relation to the Third Stage of Labour, the Nature and Cause of the Physiological Descent of the Testis, the Physiological Descent of the Ovaries in the Human Fœtus, and Mendelian Action on Differentiated Sex.

Bacteriology for Nurses. By ISABEL MCISAAC, Author of "Primary Nursing Technique," &c. New York: Macmillan. 1909. Pp. 179. Price 5*s.* net.—It is now thought by some that a course of bacteriology should form part of a nurse's training, and the standard works on nursing now include chapters on this subject. That the course should include practical work seems also desirable, but it is to be feared that the nurse's curriculum will shortly be as congested as that of the medical student. The author puts the case for a knowledge of bacteriology extremely well. She points out that "the nurse cannot protect herself nor others from contagious matter if she does not thoroughly understand the sources of infection, the methods of transmission, and the means employed to prevent it. Without a working knowledge of the technique of bacteriology she can neither grasp nor practise aseptic surgical technique, which in its elaborate detail appears nothing short of an absurdity to the ignorant, but to a nurse well trained in first principles and daily routine it becomes an instinct—as much a part of her life as the instinctive avoidance of fire or any other dangerous element." The book gives a clear and accurate, if elementary, account of the bacteriology of the most important infectious diseases, with special insistence on methods of disinfection, and the dangerous sources of infection in each disease. In most respects, however, the book follows very closely the lines of the average text-book of bacteriology for medical students and is but little modified to suit the special point of view of the nurse. The temperatures at which organisms are destroyed are so important to the nurse that very clear and even dogmatic statements are desirable on this subject, with emphasis on the fact that safe sterilising temperatures are considerably higher than those at which death of an organism takes place under special experimental conditions. The statement that spores "possess an extraordinary resistance to heat (70°–100° C.)" would be liable to produce some disastrous results if acted upon. The author appears to have accurate views as to vaccines and protective sera, and yet speaks of Haffkine's plague serum and of Pasteur's protective inoculation serum in hydrophobia. The book is well printed and attractive in appearance, and should prove of value to those readers for whom it was designed.

THE LANCET.

LONDON: SATURDAY, JUNE 11, 1910.

Hospital Sunday.

TWELVE months have gone by since last the Metropolitan Hospital Sunday Fund made its annual appeal to the public. Those who lead busy lives in London find that weeks and months slip by almost unnoticed, and many are realising almost with a shock that Hospital Sunday, which is a mark in the calendar of the charitable year, has come round once more, and that again they are being asked to help, as they have done so effectively in past years, in the fight of the poor man against pain, disease, and death. This fight is waged in our hospitals directly on behalf of a mass of helpless persons mostly drawn from the poorer districts of the metropolis, but indirectly on behalf of all those afflicted by bodily disease throughout the world. The struggle has gone on without intermission and with but little change in its general aspects during the past year. The medical inspection of school children has certainly introduced new problems into hospital administration, but has in no way changed the fact that all these charities need the open-handed aid of the public. But if there has been no change in the scientific or social work of the hospital during the year just gone, there is a great difference between the circumstances in which this collection is being held and those which have marked other years. If the collection of the present year had been held but a few weeks earlier it might have been recorded that, beyond a certain degree of political uncertainty and unrest, there was little to distinguish the season from its predecessors—little, that is to say, that concerned the hospitals of London, or that was likely to affect the collection made on their behalf by the Metropolitan Hospital Sunday Fund. Even now we find it hard to realise that which has taken place but little more than a month ago, and to gauge in its relation to the details of our civic and social life the magnitude of our national loss.

KING EDWARD VII. is dead, and, as we glance at the congregations assembled in the places of worship where collections for the Fund are made, we shall not be likely to forget that the gaiety of a London season has given place to a period of universal mourning. Let us also remember that the hand of death has not only removed a beloved sovereign from his people, but that in him the hospitals of London have lost a friend whose powerful influence on their behalf it is not easy to estimate. So much has been written in these pages and in others as to the late KING'S active interests in the results of medical research, in the welfare of his people, and in the part played by the hospitals in promoting that welfare, that these topics need not be dwelt upon at any length. It will be recalled, however, that his benevolence was not only shown in visiting the wards of individual institutions or in contributing to their resources, but in endeavouring, by the aid of his personally demonstrated good will, to strengthen the financial position of the hospitals of London as a whole. King Edward's Hospital Fund is a lasting monument of the kindly sympathy of him whose name it bears and of that business-like insight into, and appreciation of, good work done which were characteristic of him. As the result of that insight and appreciation the distribution of King Edward's Hospital Fund followed the lines which those managing the Metropolitan Hospital Sunday Fund had devised primarily for their own guidance, and no greater tribute could have been paid to the organisation of the older Fund of which KING EDWARD, then PRINCE OF WALES, had become a vice-president in 1895.

Truly in KING EDWARD the hospitals of London have lost a staunch and helpful friend, and if we remind the public of that loss we do so because we know it to be a very real one. To his successor we look with confidence for that aid in the future which his Royal father accorded in the past, but we are now dealing with the actualities and necessities of the current year. The collection for 1910 is being made during a period of mourning imposed upon all by their personal feelings and by Royal command. Many of those attracted as a matter of fashion and habit to London by the amusements which ordinary summer seasons provide are absent from it, seeking recreation elsewhere. The Metropolitan Hospital Sunday Fund collects the pence of the poor, and the sum of the offerings of those whose individual contributions are necessarily small forms a large proportion of the total amount recorded in each year. It cannot, however, dispense with the gifts of the wealthy, and if any of those who usually give on Hospital Sunday are absent on this occasion because the season's gaiety is gone, we cannot believe that on this account they will allow a cause which he had at heart to suffer loss. Let them rather remember his goodwill towards his subjects, the unfailing sympathy which he ever evinced for those who suffered in helpless poverty, the high value that he set upon the work of charity which the hospitals of London struggled to perform, and his frank recognition of the fact that that struggle was carried on in circumstances of financial difficulty. Relying upon the coöperation of his revered mother's subjects, and afterwards when their allegiance was transferred to himself, he made the cause of the hospitals of London his own, and the appeal is now to all those who were his subjects, both rich and poor, to do their utmost that in this season of mourning the collection of the Metropolitan Hospital Sunday Fund may not fall below its highest totals in the past. Let them give for the sake of the poor whose only hope of relief is in the hospitals, and let them do so with added generosity as a tribute to the memory of their dead KING, who himself knew well the meaning of bodily suffering, and who himself unceasingly, by his words and acts, showed his goodwill towards the great charitable institutions of which London and the nation are so justly proud.

On an occasion such as this we do not address ourselves to our usual readers. Upon the members of the medical profession there is no need to impress the fact that the hospitals do their good work up to the utmost limits of incomes not only insufficient but precarious, and it is not

to our medical readers that we appeal to extend those limits or to mitigate the anxiety of those upon whom the uncertainty of financial resources presses heavily. It is to a wider public that we turn on Hospital Sunday when we urge the great mass of our fellow citizens to consider what it is that the hospitals do and endeavour to do, and the ceaseless struggle in which they are engaged. Those who read our words see around them a London so vastly changed from the mother city of a century ago, when its great hospitals, or many of them, were already in existence, that it would be absolutely unrecognisable by those who knew it then. Those familiar with it 50 years since would mark a great difference if they were to revisit it to-day for the first time. Even in the last 25 years it has changed considerably. Its houses have spread and their character alters; its buildings are demolished and rebuilt; but its commerce still ebbs and flows through its streets, its docks, and its railways, while from its manufactories and exchanges its merchandise circulates the world over. As the result of this huge turmoil of labour from manufactory and railway, from dock and street, from crowded court and insanitary slum, there flows into the hospitals a ceaseless stream, an ever-growing throng of those injured by accident or struck down by disease as the direct result of their struggle to live by the work of their hands. And it is not only because the number of those needing medical and surgical aid grows greater that the task of the hospitals increases. It is because the work which the hospitals have achieved has been good in the past that they are asked to do more in the present, and there is no prospect of aught but increased toil for them in the future. They have widened their own field of labour by the explorations of science. They have trained the hands and brains of those who now save life or limb where within the memory of living man death alone would have relieved the sufferer. They restore the worker to his family where before he must have left them to starvation or to dependence upon charity, and as the result their own daily routine of duty which must be performed grows, and their anxiety lest financial stress should cause them to fail in its performance never diminishes, even though their incomes may appear to the public to be augmented substantially. There are more patients for the hospitals to deal with from year to year, not only because London grows, but because, owing to the progress of medical science, more can be done for them. Let those who are asked to give to the Metropolitan Hospital Sunday Fund remember this, and let them apply it to themselves and to the need that some day may fall upon them. It may be their lot to have recourse to the physician or the surgeon in time of bitter necessity. They can do so in the confident hope of effective aid where their fathers would have had no alternative but to face death. They may have to trust to medical science or to the skill of the surgeon to save their lives, or the life of one dear to them, when but for the work done in the hospitals there would have been no power to help them. It is to enable the hospitals of London to maintain their progress and to extend it, to do the work they have done and to increase its efficiency, that the appeal of the Metropolitan Hospital Sunday Fund is made, and is made to rich and poor alike.

In truth it is not only for alms to be expended upon the individual that we ask when we urge upon the benevolent the claims of the hospitals of our great city. During the past year attention has been constantly and insistently drawn to the importance of securing and maintaining the health and strength of the worker, not only so far as he and his immediate relatives are concerned, but for the general benefit of the community. For this awakening of the public mind to the consideration of the physical health of the people the inquiry held by the Royal Commission on the Poor-law is responsible, and in this connexion the question is often asked as to how far legislation upon the lines of the Commission's report would be likely to change the status of the voluntary hospitals by securing sufficient provision for the sick and injured poor in rate-provided institutions. The answer is that the report of the Commission, commonly known as the "Majority Report," devotes considerable space to suggestions which if carried out should increase the usefulness of voluntary hospitals by organising the service of charity, by preventing the overlapping of the work of voluntary and State-aided institutions, and by removing from the hospitals more effectually than now is possible those patients who should properly be treated at the expense of the public funds. Somewhat similar results might be expected to follow if legislation were to take place upon the lines laid down in the "Minority Report," with the difference that the latter seems to contemplate a greater enlargement of the public medical service than the first-mentioned document, a more complete departure from the existing methods and standards, and, as a possible result, a diminished scope for voluntary aid in medical as well as in other forms of charity. This is not the place to discuss the relative merits of the two reports from a medical point of view, or whether there is any immediate prospect of either being adopted in its substance by Parliament; and it is sufficient to say that in the light of neither report, nor of the discussion which has followed their publication, can be seen any likelihood that the great voluntary hospitals and the work they are achieving will be ignored or can ever be dispensed with. It should be pointed out that Poor-law legislation, when it takes place (which as far as present indications go will not be immediately), will be undertaken for the public good of the whole of the United Kingdom, and will include large areas where the medical aid provided for the poor stands in urgent need of improvement, and where the question of such aid is affected but little, or not at all, by the existence of voluntary hospitals.

The voluntary hospitals of London are not local but national institutions, and their municipalisation would be attended by a limitation of their benefits to the community not likely to be contemplated seriously by the legislature in our times. They open their doors without consideration of county or borough boundaries or of qualifications of settlement, as they do without distinction of nationality, creed, or character. They give their aid freely, having regard only to the physical need and poverty of the applicant, and are limited in their work of benevolence only by their

own inability to supply more than that which the generosity of the kind-hearted enables them. Upon that generosity the Metropolitan Hospital Sunday Fund relies for its existence, and in endeavouring to bring home its claims to all who read these words we would lay stress on these points. That they should give, and give freely, not confining themselves to any sum which they may regard as their usual Sunday offering, but making this particular Sunday one of unusual significance. That they should make it an occasion for an act of self-denial, if such be necessary, in order that the hospitals may profit. A pleasure or a luxury foregone should render the giving a more pleasant subject of reflection for the giver. That they should give in any event, whether attending worship in the metropolis or not. We have spoken above of those absent from London during the present season. Let them and let all who leave London, whether for a longer or a shorter period, not forget to forward their contribution if they do not attend divine worship where a collection on behalf of the Fund is made. And givers should remind others to give, so that none may forget, and so that all, both young and old, may be unable to plead any excuse based upon ignorance or thoughtlessness for not contributing to the best of their ability. Upon children no less than upon their older relatives we urge the duty of giving and of reminding others.

The Publications and Work of the Research Defence Society.

THE annual meeting of the Research Defence Society was held on Friday last, June 3rd, and was a well-attended and important affair. The proceedings, as well as a valuable address by Sir DAVID BRUCE, will be found fully reported in our columns this week (see p. 1635), and we propose to confine our remarks here for the most part to notice of the publications of the society. This society was founded only a little more than two years ago with the object of making the truth about experiments on animals known to the general public. The opponents of vivisection have until recently had matters very much their own way. They have made statements sometimes resting on a basis of fact, and sometimes dependent merely on imagination, and the public have received these statements and have only too often accepted them and the deductions made from them as absolutely true. For more than 30 years the societies which oppose vivisection have endeavoured to persuade those who knew nothing much about the matter that the men who perform physiological and pathological experiments, and employ animals for this purpose, are in the habit of torturing them. The Research Defence Society endeavours by lectures and by pamphlets to make known widely the objects of these experiments, the value of the experiments themselves, and the beneficial results which flow from them. The pamphlets issued by the society are many, and those who read them cannot but admire the spirit of moderation with which they are written. The claims they make, that benefits have followed from these experiments, are in every case well within the truth, and they must serve to carry conviction to unbiassed minds.

All who know anything of the real truths of modern medicine appreciate the vast importance of the advances which have been made within recent years in the treatment of diphtheria, and one of the leaflets issued by the society deals with diphtheria and its antitoxin. It points out the nature of diphtheria and the serious results it produces, and it shows how many lives were lost in days gone by. It explains how the antitoxin is prepared and how experiments on rabbits and horses led to its discovery, and lastly it shows the enormous benefit that has resulted from the employment of antitoxin in cases of this disease. It is a very temperate statement and should prove useful in making more widely known the nature and value of diphtheria antitoxin. Another leaflet deals with inoculations. It is often urged by writers in antivivisection literature that an enormous number of experiments on animals is performed every year in this country, and they quote the returns of the inspector under the Vivisection Act as a proof of the great number of experiments made, but they do not take the trouble to explain, and it is possible that even they themselves do not know, that 97 per cent. of all experiments on animals consist of inoculations, together with a few experiments for the testing of drugs or food. The leaflet explains the very painless nature of an inoculation, that it cannot with any justice be called an operation, and proves that it is absurd to speak of many thousands of operations on living animals being allowed by the law. The leaflet quotes a good instance of the misuse of the word vivisection as applied to some of the experiments. During 1908 12,500 experiments were made on behalf of the Royal Commission on Sewage Disposal. These experiments were made on fishes or their eggs to test the purity of water. Surely it might have been thought that the most rabid antivivisectionist could not have objected to these experiments, seeing the possibly incalculable life-saving that might result from them, yet, under the present Act of Parliament, every one of these 12,500 experiments on eggs and fishes has to be reported to the Home Office as an "Experiment on the living animal calculated to cause pain," and the antivivisectionists cry, "Look at the increase in the number of vivisections in this country." Even when a real vivisection is performed, and it must be remembered that only 3 per cent. of all the experiments on animals in this country are cases of real vivisection, the animal must during the whole of the experiment, save in very exceptional circumstances, be under an efficient anæsthetic, and if the pain is likely to continue after the effect of the anæsthetic has ceased it must be killed before it regains consciousness; otherwise it may be allowed to survive the operation, but even then if pus should form the animal must be killed. The law cannot be called inhumane, and we wait with confidence in this direction the long-delayed report of the Royal Commission on the subject.

Another pamphlet deals with charges of cruelty recently made against the Rockefeller Institute of New York. In the early part of last year the New York Antivivisection Society brought various charges of cruelty against the Rockefeller Institute, but unfortunately for the society the witnesses on whom they relied were hardly trustworthy. The chief witness was a scrub-woman, and she stated under oath that

employment in the operating-room was very distasteful to her because of the cruel way in which the animals were treated. Therefore it is interesting to note that she caught and took in a bag to the institute the pet cat of her neighbour and offered it for sale for 35 cents. The offer was declined. The other two witnesses were ex-employees discharged for sufficient cause, and an examination of their charges proved their lack of foundation. Another pamphlet, which should prove of great interest to the non-medical public, gives an account of a visit by a lady to the Lister Institute of Preventive Medicine. In it she tells what she saw and describes the kind of work which is done there, and she explains some of the benefits derived from the inoculations and experiments performed. We need not say much of the leaflet dealing with the "Brown Dog," and will merely mention that it gives a dispassionate account of the facts. One of the most striking of the pamphlets deals with recent surgical progress, and is written by Professor W. W. KEEN, the famous surgeon of Philadelphia. In this reprint from *Harper's Magazine* Professor KEEN shows how greatly recent surgical progress has depended on experiments on animals. He refers especially to the surgery of the heart and the blood-vessels. The transplantation of organs is just at its beginning, and it is only by suitably chosen experiments on animals that the best direction of effort can be certainly discovered. Lord CROMER, in his forcible speech at the meeting of the Research Defence Society, laid stress upon one of Professor KEEN'S points that in all the years during which the antivivisection societies have existed the opponents of experimental research have done nothing but stand in the way of progress; not a single human life has been saved by their efforts, not a single household has been made happy, not one disease has had its ravages abated.

That some sort of control should be held by the law over experiments on animals may be allowed, but the endeavour of the present day is not only to hamper these experiments, but to vilify the operators, and to try to throw discredit on the results which their discoveries have given us. We believe that in this matter the public will judge rightly, if they know the truth; and the work of the Research Defence Society is to bring before those who, directly or indirectly, can affect legislation the truth of the matter, the facts of vivisection, and the results that follow. To Lord CROMER, the Hon. SYDNEY HOLLAND, and especially Mr. STEPHEN PAGET, the public owe a debt of gratitude for their ungrudging labour and zeal in the cause of humanity.

Biological Analogies in History.

MR. ROOSEVELT'S Romanes Lecture, delivered in the Sheldonian Theatre, Oxford, on Tuesday last, had a great reception. It is inevitable from a political point of view that some of the ex-President's breezy pronouncements should not find favour in this quarter or in that. He is a critic at large, and some of the criticised may not feel quite certain that he possesses all the equipment necessary for his inclusive scope; he speaks from the heart and has not hesitated in the cause of truth to say many unpalatable things. Moreover, his style of oratory, his methods of argument, and his messages of advice are all extremely simple; it is not possible for those who have been reproved to mistake the meaning of his words, or to attribute to him any views save those which he has enunciated. The same qualities of clearness and simplicity, which have characterised his oratorical deliveries throughout his tour, were present in his Romanes Lecture, and here, being applied to a subject eminently scientific in its nature, they will have secured for him the support of the medical profession.

It is impossible to define in exact terms the extent to which the facts of biology can be employed as aids to the interpretation of history, or to say what help the study of biology can be to those who are attempting to arrive at a solution of the racial and social problems of to-day. It is certain that many scientific philosophers would make very poor proconsuls, and, though it cannot be denied that many professional diplomatists are practical failures, no one would advocate replacing a Foreign Office official by a microscopist. But the methods of science are none the less the methods that will have to be applied in the future to the development of States. There are quite strong analogies between some of the groups of animal life and the national entities of history. The changes which are known to have occurred in certain biological families can be compared, as Mr. ROOSEVELT pointed out, with those seen in the civilisations which have at different times spread over the world's surface, struggling, rising, falling, and disappearing. Just as a species may become extinct either by dying out or by undergoing such complete modification under changing conditions that it loses its original identity altogether, so human societies disappear or rise to prominence, develop changes, and specialise to such a degree as to bear but slight resemblance to their prototypes. Admitting this, it becomes obvious that in order to obtain any adequate knowledge of the life of a certain nation methods as scientific as those adopted in the study of the life and habits of a biological species ought to be employed.

Mr. ROOSEVELT emphasised this necessity in saying that history should be treated as a branch of science—as a scientific record by which we can appreciate the successes and failures of various experiments in the past, and learn from them how to shape our course in the future. But at the same time he insisted that history should also remain a branch of literature. Here we are entirely in agreement with Mr. ROOSEVELT, but he is making a large demand; for a scientific history to be useful ought to be quite intelligible to persons of ordinary education, and the writing of such works would be very difficult. Knowledge, minute and general, is what the world really wants, and that knowledge must be acquired on scientific principles. Those who administer the affairs of alien nations deal with people about whom they really know very little and about whose history they know less, yet the whole development of the world is a matter of inter-relation between aliens. As the biologist examines an animal whose habits he wishes to find out, so the rulers of various nations must make scientific examination of the history and habits of the alien nations whom they aspire to rule. And for their guidance a literature containing the proper blend of history and science will be invaluable—but it remains to be written.

Annotations.

"Ne quid nimis."

GOVERNMENT SUBSIDIES FOR SCIENTIFIC RESEARCH.

IN connexion with the annual grant voted by Parliament in aid of scientific investigations concerning the causes and processes of disease, Mr. Burns, the President of the Local Government Board, has authorised the following special researches:—

1. A continuation of an investigation into protracted and recurrent infection in enteric fever, by Dr. Theodore Thomson, medical inspector of the Board, in conjunction with Dr. J. C. G. Ledingham of the Lister Institute.
2. A continuation of an investigation into protracted and recurrent infection in diphtheria, by Dr. Theodore Thomson and Dr. C. J. Thomas.
3. A continuation of an investigation into flies as carriers of infection by Dr. S. Monckton Copeman, medical inspector of the Board, in conjunction with Dr. G. S. Graham-Smith and Mr. Merriman of the University of Cambridge, Dr. Nicholl of the Lister Institute, and Dr. J. M. Bernstein of the Bacteriological Laboratory, Westminster Hospital.
4. A continuation of an investigation on the injurious gases evolved during artificial illumination, by Dr. J. Wade, D.Sc., of Guy's Hospital.
5. A preliminary inquiry into the relationship of certain special types of bacteria to the diarrhœa of infants, by Dr. C. J. Lewis of Birmingham, Dr. Sheila M. Ross of Manchester, Dr. Thomas Orr of Shrewsbury, and Dr. R. A. O'Brien of the Lister Institute.

The researches subsidised by Government are all, it will be seen, of the exact type to which public money should be devoted. Their aim is to improve the public health in the largest sense, a remark which especially applies to the new inquiry dealing with the diarrhœa of infants, that appalling scourge of the newly born.

NE QUID NIMIS IN ATHLETICS.

FRANCE, and more particularly Italy, should ponder well the saying of Talleyrand, "surtout point de zèle" in the new departure they are both taking in the field of athletics. Hitherto neither country has shown much liking or aptitude for the games so high in favour with ourselves—the fencing saloon or the pistol gallery absorbing the time devoted in England to cricket or football. Now, however, both Italy and France are taking kindly to these *al fresco* pastimes, football especially, and the press, Italian as well as French, is week by week recording the matches of rival teams with a fulness and a zest that imply a growing interest in the game bidding fair to equal that entertained by the country of its origin. The last notable encounter of a French with an Italian "squadra" (team) took place the other day at Milan, when the latter came off the victor, amid a scene of the wildest enthusiasm, by six goals to two. So far both countries are to be congratulated on their adoption of a game which, in the opinion of such medical authorities as Professor Mosso of Turin, who is said to have introduced it to his compatriots, is fraught with benefit to the youth already so proficient in its practice. But there are other forms of athletic pastime by no means so salutary to its young votaries—we mean the bicycle contests "round Italy," in which the palm is won by the performer who can combine speed with endurance over the greatest number of miles. The second "giro d' Italia" has just come off and the state in which the young competitors were seen by an eye-witness to arrive at his "coign of vantage" between Ancona and San Benedetto del Fronto was such as to evoke the greatest misgivings as to the results of the competition on its participants. "Those youths," he says, "who, either singly or in groups, reached that intermediate stage, exhausted and panting, were stretched on tables on which they rocked and shifted uneasily in distressing dyspnœa, hardly able to write the signatures required of them by the conditions, their sign-manual being all but illegible. Semi-comatose or seemingly stunned, as by the blow of a mace, they offered a spectacle truly pitiable, inspiring the beholder to lose no time and spare no effort in denouncing such competitions as unworthy of a civilised people. So practised, bicycling must prove disastrous to youths who are tempted to compete in those matches by the prospect of gaining a few thousand francs—at what an inevitable risk to future health and life itself one shrinks from contemplating!" An appeal is made to the press not to hold out prizes for such competitions, but on the contrary to use its influence in discouraging them by giving publicity, under authoritative medical names, to the lesions, profound and permanent, incurred even by the most robust of "corridori." The passion for athletics, now at high pressure throughout the Latin countries, may be an inestimable advantage to both—only, however, in the degree in which it is rationally utilised and not allowed to degenerate into "Marathons" and "giri d' Italia" resulting in over-strain or premature impairment of what the older physicians called "the tripod of life."

PATHOLOGICAL ASSASSINATION.

IT is a question if a parallel can be found among Western nations or savages at large to the use of the "larang," which means in the Malay language "the forbidden," and is used in Southern China and the Malay countries, such as Sarawak, for purposes of assassination. Mr. W. H. Battle, in his recent oration on Internal Injuries delivered before the Medical Society of London, exhibited a larang belonging to Dr. White-Hopkins, who has been resident for some years in Sarawak.[1] In shape the instrument resembles an iron dagger, and it is probably made out of a large timber nail, to which, with the aid of twine, an ornate curved cross-piece is fitted. The head of the nail is held so as to protrude from the loose sleeve of the malefactor who uses it. A stroke from this nail on the abdomen of a victim frequently brings about the latter's death from ruptured spleen, the calculation of Chinese assassins being that some 90 per cent. of those they attack are suffering from splenomegaly due to malaria. The nearest approach to this truly fiendish form of assassination discoverable in the annals of legal medicine is murder by infection. In a case now *sub judice* in Russia a suspicious death is attributed to subcutaneous infection by cholera virus. Quite recently also a medical man, Dr. Clarke Hyde of Kansas City, has been condemned to imprisonment for life for the murder of three victims, who with eight others he is supposed to have infected with the virus of typhoid fever. This, we think, must be one of the first instances of a culture of a pathogenic germ being used for criminal purposes. It is, as the writer points out, a method capable of great extension, and likely to trouble the medical legists of the future, though fortunately its use will be necessarily restricted to persons with some knowledge of bacteriology. Among primitive peoples the belief in murder by infection has often been entertained—as, for instance, by modern Russian peasants, who accuse medical men of deliberately spreading (on the principle of breaking windows to do good to the glaziers) the disease they have been striving to prevent. Then there are the historic cases of the plague-poisoners of Milan and Geneva, who in the seventeenth century were accused in numbers of disseminating the plague with the help of poisoned ointments, infected clothes, and so forth, in the interests of nurses and all the other employees of epidemics. Searching in works of travel one finds sometimes isolated cases of explorers being apparently allowed to die by sledge-drivers, guides, and others who have been interested in the loot of their master's property, and these

[1] THE LANCET, May 28th, 1910, p. 1475.

cases are analogous, as the murder is done by enlisting the services of disease. Thus, in Dr. J. J. Hayes's "The Open Polar Sea," the death of a Mr. Sonntag is described, who, when manifestly suffering from a chill during a long sledge journey, was nearly drowned, and died presumably of cold shortly afterwards. The Esquimaux driver who was with him gave an unsatisfactory account of his death, and Dr. Hayes implies that foul play was suspected. The larang users, however, with their knowledge of a pathological condition and their calculation of probabilities, are easily ahead of all other competitors in iniquity.

THE DEVELOPMENT OF TRYPANOSOMES IN TSETSE FLIES.

THE Sleeping Sickness Commission sent out in 1908 to Uganda, under the leadership of Sir David Bruce, has recently presented another interesting and valuable report which has been published in the Proceedings of the Royal Society, on its experimental work in connexion with the development of trypanosomes in tsetse flies. These experiments were undertaken to study the development of Trypanosoma gambiense, as well as of T. dimorphon, T. nanum, and T. vivax in Glossina palpalis. In each instance the experiment with T. gambiense was carried out in the same manner, the tsetse flies being fed first for some days on highly-infected monkeys and afterwards on healthy monkeys. As T. vivax does not affect monkeys, cattle and goats were substituted in the experiments with this parasite. At first only wild flies captured on the shores of Lake Victoria Nyanza were used, since there seemed to be an inexhaustible supply of them. But later, when experience had shown that about one fly in 400 or 500 of these wild flies was naturally infected, it was thought that their employment might lead to error. Therefore a second series of experiments were carried out with laboratory-bred flies, hatched out mainly from pupæ collected on the sandy shores of the Sesse Islands in the Victoria Nyanza. Numerous observations have shown that there can be no hereditary transmission of trypanosomes in the Glossina palpalis; nor has any evidence been found to prove that these flies can become infected with any flagellate by means of contact with other flies, or through fouled cages. Any trypanosomes, therefore, which may be discovered in a laboratory-bred fly must be considered as having been derived from the infected animal on which it has been fed. With the wild or lake-shore tsetse flies 14 experiments were carried out, 1840 flies being employed, none of them being naturally infected at the time they were captured. In seven of the experiments, involving the use of 880 flies, an average of 126, the results were positive; in the other seven, 960 flies, or an average of 137, were used with negative results. The shortest period before a fly became infected was 18 days, the longest 45, and the average 32 days. Of the 1840 wild flies thus employed only 16 were found to have become artificially infected with T. gambiense, or at least had flagellates in their gut. With regard to the results obtained with laboratory-bred tsetse flies, 42 experiments were carried out, 34 of them being negative and only eight positive. In the eight successful experiments 371 flies were used, an average of 46. The shortest time that elapsed before a laboratory-bred fly became infected was 27 days, the longest 53, the average being 36 days. Some curious results were occasionally noted. For example, at the end of one experiment 12 flies survived and were submitted to dissection and careful examination, none of them, however, being found infected; but they were "pooled" and injected into a healthy monkey, with the result that it developed sleeping sickness. It therefore appears possible that infection in the fly in certain circumstances may escape detection by the ordinary microscopic methods. In several instances flagellates were found in the gut of the flies, but these did not convey infection to the healthy monkey on which they fed, nor did injection of the fluid from the gut of these insects give rise to any positive result. So that from this it appears possible for some flies, although themselves infected, to be unable to convey the infection to the animals on which they feed. In these latter series of experiments 746 laboratory-bred flies were employed, of which only 39, or rather more than 5 per cent., became infected with T. gambiense. Another set of experiments were carried out to investigate the development of Trypanosoma dimorphon, the commonest cattle trypanosome in Uganda, T. nanum, and T. vivax in the Glossina palpalis. In experimenting with T. vivax in laboratory-bred G. palpalis, 178 flies were used, and of these 30, or 17 per cent., became infected. In all of the 30 flies except one the infection was confined to the proboscis. Infection of the proboscis with T. gambiense was only seen on one occasion. The conclusions arrived at by the Commission in its report may be summed up as follows: T. gambiense multiplies in the gut of Glossina palpalis in about one in every 20 flies fed on an infected animal; the flies become infective on an average 34 days after their first feed on infected blood; and a fly may remain infective for 75 days. With regard to T. dimorphon, T. nanum, and T. vivax, they may also multiply in the G. palpalis, which, therefore, must be looked upon as a possible carrier of the infection of these diseases. The Commission was also of opinion that the growth of flagellates in the proboscis of Glossina palpalis was characteristic of Trypanosoma vivax.

A JOURNEY THROUGH THE AIR FROM A MEDICAL STANDPOINT.

RECENT achievements in the science of aero-travelling have given a decided stimulus to the idea that general locomotion through the air is within sight. It certainly seems that difficulties are rapidly being surmounted, but still the risks are very great; the weather must be favourable for one thing, and then there must be no hitch in the motor engine. After all, no air-trip as yet can be started with the same certainty as a trip by land or by sea. The method of progression is under fair control, but stability under all conditions is not yet amongst the triumphs won. Supposing, however, that it was, the fact has then to be realised that a trip through the air will involve a good deal of nerve. The giddy height will have to be faced, the sudden swoop down or rise upwards with their disagreeable effects for a great many people will have to be reckoned with. Sea-sickness is a terror to many people, and the chances are that air-sickness will be worse. Most persons again have experienced the unpleasant feeling in a lift when it commences its descent or in a swing when, like the pendulum, it swings back. Not a few people refuse to stand close to the edge of a cliff or to trust themselves to look down into a vast chasm of space immediately beneath their feet owing to vague feelings of giddiness, fears of falling arising out of a sense of a jeopardised equilibrium. And yet these same people converse glibly about the nearness of the day when aero-traffic will be an accomplished fact, and point in support of their view to the enormously rapid advances which motor traffic in the streets has made. When the question is carefully considered in detail it will be conceded that there is hardly anything that is comparable between the air motor and the land motor from the point of view of attaining practical success. The problem in the case of the former is so complicated by the first requirement—the conquest of that great force which, do what we will, pulls us back again to earth the moment we dare to rise from

its surface. No special motor appliance is required to keep afloat on the sea or to keep a stable position on land, but we can only gain support in the air by means of moving machinery analogous to the wings of a bird or by utilising a buoy or a substance which is much lighter than air, and which, therefore, tends to float upon it. The machinery in the former case must obviously be well-nigh perfect and incapable of breaking down, while the difficulty in the latter case is the enormous bulk of floating gas that must be used. In short, the advances yet to be made in order to bring aviation within the practical affairs of daily life must still be very far-reaching. Then, assuming the great consummation has been reached, will the human organisation be able to stand aviation? This is by no means certain, having regard to the constant changes of atmospheric pressure—with their marked effects upon the respiratory and circulatory processes—which a journey through the air must entail.

THE RADIOGRAPHY OF THE RENAL PELVIS AND URETER.

EVERY year the applications of the Roentgen rays are increasing in number. Only a short time has elapsed since the great value of these rays in determining the size, shape, and position of the various portions of the alimentary canal was first recognised, and they are at the present time in daily use in clearing up obscure points in cases of disease of these organs. One of the most recent uses of the X rays has been described by Dr. Edward L. Keyes, junior, of New York city, in the third volume of the Transactions of the American Urological Association, where he has given an account of his studies by means of X ray pictures of the pelvis of the kidney and the ureter. While the physiology of a diseased kidney is best studied by means of the examination of urine withdrawn by a ureteral catheter, up to recently it has not been possible to learn much before operation of the gross changes. Palpation of the kidney is of comparatively little value; the kidney is deeply situated and not much is to be learnt by this method. The ureteral catheter has given a little information as to patency of the ureter, the presence of stone, or the amount of renal retention in the pelvis, but radiography will supply information not attainable in any other way. When it is employed unaided it shows with a great deal of certainty the presence of urinary calculi and sometimes the outline of diseased kidneys. A catheter capable of giving an X ray shadow has also been introduced into the ureter, and then a skiagram has been taken, but the information thus obtainable is not great. Dr. Keyes has employed a method in which he has taken skiagrams after injecting into the ureter and renal pelvis fluid capable of casting shadows. Bismuth in suspension, so satisfactorily employed in the case of the alimentary canal, is obviously objectionable for kidney work, for if any solid matter be introduced into the pelvis of the kidney it may easily form the nucleus of a calculus. After many experiments, he found that the most satisfactory fluid was a 50 per cent. solution of argyrol. The following is the method employed. A preliminary skiagram is taken to show a stone or any marked gross change in the condition of the kidney; then both ureters are catheterised, the catheters being inserted, if possible, as far as the pelvis of each kidney. Then the freshly prepared argyrol solution is slowly injected by means of a syringe, and the injection should be discontinued at the first suggestion of pain in the loin. As soon as both sides have been injected the X ray picture is taken, and immediately after the skiagrams have been taken the fluid is allowed to run out, otherwise renal colic may occur. The results obtained by this method are claimed as very satisfactory. Even without distending the pelvis fully the outline can be seen, and it can be recognised whether hydronephrosis is present or not. Dr. Keyes quotes three cases illustrative of the value of the method, and he gives some illustrations of the skigrams taken. The method has certain disadvantages; the solution of argyrol is uncleanly and it irritates the patient, and distension of the renal pelvis may cause pain; but the pain of injection can be minimised by injecting very slowly, and the value of the information obtained may well outweigh a little discomfort.

BESPECTACLED SCHOOL CHILDREN.

RECENT developments of school medical inspection and of the necessary treatment of defects discovered during such inspection have filled the minds of not a few with the dread that ere long our child population will be tied as securely to the doctor as they are proverbially supposed to be to their mothers' apron strings. And not the least alarming is the prospect conjured up by some recent figures that hosts of our chubby-faced little ones will be forthwith bedecked with hideous iron-framed spectacles, a prospect no more pleasing than our pet dogs in muzzles or the apocryphal caricatures of the big-headed bespectacled German child! Part of this apprehension arises from a failure of those who deal out figures to supply anything like a standard of comparison against which their figures may be measured. Such a letter as appears in the *Times* of June 2nd over the signatures of the Princess Christian and Lady St. Helier is a case in point. Appeal is made for funds for the supply of spectacles to poor children, and a list of hospitals is given where arrangements have been made for the examination of London school children whose sight is defective; no less than 17,190 children are expected to be examined each year under these arrangements. The total sounds huge, and the prospect of such an array of spectacles appalling to any except, perhaps, the maker of these aids to vision. In considering such a prospect two factors must be borne in mind: (1) that these 17,000 bear but a small proportion to the whole London elementary school population of 800,000; (2) that not all of these 17,000 will be required to wear glasses, or at least not permanently. In an examination of 1100 of these very children sent from London County Council schools to two of the London hospitals Mr. Bishop Harman[1] found the variety of defect (excluding cases of disease, scarred corneæ, &c.) worked out as follows:—

Hypermetropia.	Hypermetropic astigmatism.	Mixed astigmatism.	Myopia.	Myopic astigmatism.	Odd eyes.	Totals.
468	315	78	102	115	22	1100
42·55	28·64	7·09	9·27	10·45	2	100

The first two groups of hypermetropia and hypermetropic astigmatism form 71 per cent. of the total, and these sorts of "defects" are the natural state of man, and for the most part only cause trouble when health is poor, close work excessive, or accommodation lost by reason of age. Lumping together the remaining cases as "myopia"—a most generous allowance to that dread of the school hygienist—there were 29 per cent. Since these figures are for a block of defective children estimated as one-tenth of a full school roll, it follows that really bad vision afflicts only some 2 to 3 per cent. Those who bear in mind the classical figures of Cohn of the prevalence of myopia in German schools can take comfort at this small proportion. Still, it remains a matter for reflection that at least 5 per cent. of our school-children

[1] Proceedings of the Royal Society of Medicine, vol. ii., No. 7, p. 206 (Children's Section), May, 1909.

will in the near future wear spectacles, half of them continuously and half of them for school work only. And since it is within the knowledge of those most in touch with the schools that the average of defect is higher in the poorer than the better-class elementary schools, this special appeal for monetary aid is justified. Poor vision is too great a disability to a child for it to be left unremedied, and difficult vision, such as is presented by astigmatism, too great a strain to add to the child's already sufficiently heavy tasks.

THE TREATMENT OF WOUNDS OF THE HAND WITH TINCTURE OF IODINE.

As stated in a recent annotation[1] the use of tincture of iodine for disinfection of the skin before operation is becoming more general. It has the great advantage of simplicity over older methods and appears to be perfectly reliable. We are indebted for the method to French surgeons. Nearly half a century ago Boinet, an excellent surgeon, insisted on the value of tincture of iodine in surgery and published a large volume entitled "Traité d'Iothérapie." It is interesting to remember that this occurred before the introduction of Lister's antiseptic system. But Boinet's teaching was not heeded in his time and only recently has it been revived by his countrymen. At a meeting of the Académie de Médecine of Paris recently Professor Paul Reclus called attention to the great value of tincture of iodine in the treatment of wounds of the hand, and the law on accidents in France, like the Workmen's Compensation Act in this country, has of late given special importance to such matters. As the hands of workmen are often callous, fissured, and covered with a blackish crust which contains grease, epidermal débris, and dust in which bacteria flourish, preliminary vigorous disinfection is usually recommended. Ordinary antiseptics are insufficient and recourse is had to ether, turpentine, benzine, or petrol. After this the hand is washed for a long time in soap and warm water. But this method is sometimes inefficacious; microbes carried by the liquids are inoculated into the wound and produce inflammation in spite of the most reputable dressings, moist or dry, aseptic or antiseptic. The new method is much simpler; it consists in painting the wounded region with tincture of iodine. A sterile brush is plunged into the flask containing the tincture and a coat is deposited around as well as on the wound as soon after the injury as possible. The alcohol is allowed to evaporate. When the surface is dry it is covered with an aseptic compress and a pad of absorbent cotton-wool which are secured with a bandage. In the evening or on the next day the application is repeated, and then at longer intervals until the wound is not touched for three or four days. It is important to remember that the application of the iodine should not be preceded by swabbing or washing of the wound, which is not only useless but injurious, because it disseminates microbes and because the iodine does not penetrate so well through skin soaked in water; the disinfection is therefore less reliable. Reclus insists on another condition: the tincture of iodine must be fresh. After it has been prepared eight days it is too "old"; it gradually loses some of its qualities and becomes irritating to the tissues and when applied to the wound causes much pain. If fresh tincture is used only some smarting is produced. In civil practice this method is a great advance, but in war it constitutes a veritable revolution. At the front cleansing and bathing of wounds are impracticable, yet failing the treatment now recommended they are necessary. The ground contains pathogenic microbes and the soldiers' hands are soiled in throwing up the mounds behind which they shelter. In a few minutes the iodine brush can be passed over the wound and a compress applied. This is not mere theory, for tincture of iodine was largely used in the Russo-Japanese war, and this is one of the causes of the success of the treatment of wounds in that war. The efficacy of the treatment equals its simplicity and seems to be due to the penetrating power of the tincture of iodine. Walther has shown that in less than seven minutes after it is applied to the skin the epidermis is sterilised down to its deepest layer and fragments removed do not yield cultures. The bactericidal effect is possibly increased by dehydration of the tissues, which are hardened. Under the older methods some cases of phlegmon, less diffuse and spreading than before the antiseptic period, are observed; under tincture of iodine they are never seen. The hand is a very complicated organ, containing many tendon sheaths and joints, the spread of inflammation to which may produce permanent stiffening. Since adopting the iodine treatment Professor Reclus has never seen this result. In adopting a conservative treatment of crushed fingers, particularly of the crushed thumb (of which it is important for purposes of prehension to save even the smallest part), the iodine treatment is of great value, for it prevents inflammation which leads to ankylosis. So convinced is Professor Reclus of the value of this treatment that he thinks that in every ambulance, train, and railway station there should be a flask of tincture of iodine which should be renewed every week. It seems to us that the inconvenience of renewing the tincture should be avoided and that it should not be beyond the powers of chemistry to produce a suitable stable preparation. In our previous annotation we stated that another French writer, Dr. Chassevant, has recommended a 1 in 15 solution of iodine in chloroform for disinfection of the skin as preferable to the tincture of iodine; he claims that it is less irritating than even the fresh tincture and perfectly stable.

[1] THE LANCET, March 26th, p. 874.

THE DIAGNOSIS OF PULMONARY EMBOLISM.

IN the *Boston Medical and Surgical Journal* of April 28th Dr. G. G. Sears points out that pulmonary embolism is more common than is usually supposed and is often overlooked because not considered in differential diagnosis. In the post-mortem room pulmonary embolism and infarction are not uncommonly found. They occurred in 106 out of 3006 necropsies (3·5 per cent.) performed at the Boston City Hospital. Some cases escape detection because no symptoms are produced; others because the embolism is a terminal event in a patient who is seriously ill or even *in extremis*, the symptoms being confounded with those of the primary disease. Between cases in which no symptoms are recognisable and those in which life is suddenly ended by syncope or asphyxia from plugging of a primary branch of the pulmonary artery, symptoms of all degrees of severity occur. The most important are sudden pain in the chest, dyspnœa, cough with bloody expectoration, irregularity and weakness of the heart, cyanosis, exophthalmos, dilatation of the pupils, and cold sweating. To these may be added chills, fever, great restlessness, delirium, opisthotonos, convulsions, or coma. If the occluded vessel is large enough to produce an infarct 4 or 5 centimetres in diameter there may be subcrepitant râles and signs of consolidation of the lung. The diagnosis rests on the sudden onset of pulmonary symptoms, more or less intense, associated with circulatory disturbances, which may vary from slight elevation of the pulse to serious cardiac failure, combined with a source of embolism such as advanced cardiac disease or venous thrombosis. But embolism may occur before there is any evidence of thrombosis, either because the thrombosis is situated in a small vessel and causes no symptoms or does not occlude a large one

sufficiently to block the circulation. Even at the necropsy the source may not be discovered, either because the thrombus has been completely detached or because the affected vein is outside the usual field of the post-mortem examination. Of 41 cases attributed to peripheral thrombosis in the Boston City Hospital series, the particular vessel affected was not identified in 17, through the locality was indicated by an inflammatory condition associated with some lesion such as an operation wound or ulceration or sloughing in various parts of the body. A thrombus was found in only 29 out of 54 cases in which it was probably of cardiac origin. Not even a probable source of embolism was found in six cases. The most characteristic symptoms are dyspnœa, cough with bloody expectoration, and pain. But the suddenness of onset alone gives the first significance, and the other two are so infrequent that their absence is of little importance. Signs of consolidation of the lung may assist the diagnosis, but may also lead to error by suggesting pneumonia. The grouping of the symptoms may suggest several diseases—cardiac asthma, acute dilatation of the heart, angina pectoris, pneumonia and pleurisy, and neuralgia. Signs of disease of the arch of the aorta or coronary arteries with attendant myocardial weakness, and a history of a feeling of oppression some time before the paroxysm, may point to cardiac asthma. The diagnosis from acute cardiac dilatation with pulmonary œdema may not always be possible. A lack of adequate cause for acute dilatation, especially if a small patch of pulmonary consolidation is found, points to embolism. In another type angina pectoris is simulated, and if sudden death follows differentiation may be impossible unless a history of previous anginal attacks can be obtained. The diagnosis from pleurisy or pneumonia may present peculiar difficulties, especially in post-operative and puerperal cases.

THE INTERNATIONAL MEDICAL CONGRESS, 1909.

IN the course of the last week the Executive Committee of the Sixteenth International Medical Congress held its closing meeting. The Transactions of the Congress, which cover 800 printed sheets, give a valuable *résumé* of modern medical science. The expenses of the Congress have been covered partly by the Government and partly by the municipality of Budapest, each contributing 100,000 crowns, these sums being in addition to the membership fees. The balance sheet shows a surplus, part of which, amounting to 20,000 crowns, will be used to found a "Prix de Budapest," a prize which will remain in the gift of the Medical Faculty of the Budapest University. The first distribution of this prize will take place at the next International Medical Congress in London in 1913. The documents referring to the late Congress will now be transferred to the new Permanent International Committee, but all information regarding its transactions will continue to be given for this year by the general secretary (Budapest, VIII., Mária-utcza 39). The "Album" which was brought out on the occasion of the Congress was a private undertaking, having no connexion with the office of the general secretary, and all inquiries referring to it should be directed to the Editor of the Album, Budapest, VI., Liszt Ferencz-tér 4.

YELLOW FEVER IN WEST AFRICA.

IN view of statements which have appeared in the press with regard to the outbreak of yellow fever in West Africa it is thought desirable to state that since May 13th, when the outbreak was first reported, there have been 12 cases in all, 9 at Sekondi and 3 at Freetown. All the cases have unfortunately proved fatal, and, with three exceptions, those attacked were Europeans. No fresh case has occurred at either port since May 26th, and no cases have occurred at any other place in British West Africa. As soon as the outbreak was reported a meeting of the Advisory Medical and Sanitary Committee for Tropical Africa was summoned, and two subsequent meetings have been held in connexion with the outbreak. Lord Crewe has acted throughout on the advice of the committee. As soon as it was certain that the disease was yellow fever Lord Crewe was glad to avail himself, with the consent of the corporation and the University of Liverpool, of the offer of Sir Rubert Boyce to proceed to the West Coast to assist in organising measures for stamping out the disease. Sir Rubert Boyce accordingly proceeded to Sekondi on June 1st, as our Liverpool correspondent announces, accompanied by six medical men specially appointed for this purpose. Two medical men were simultaneously sent to Freetown. Stringent precautions are being taken at both the affected ports and at the other British ports in West Africa to prevent the spread of the disease.

THE LONDON COUNTY COUNCIL AND THE MEDICAL INSPECTION OF SCHOOL CHILDREN.

THE greater part of the sitting of the London County Council on June 7th was devoted to the preliminary consideration of the annual education estimates. The cost of medical inspection accounted for an increase of £3615, and medical treatment added £4000. Mr. R. A. Bray, in the course of a general debate, remarked that medical inspection of school children in London was in a profoundly unsatisfactory condition. The County Council had fallen far short of the Board of Education's minimum requirements, and with the staff they would have in September they would still be behind. With that staff about 150 schools could be inspected in a year, and there were 900 schools in the administrative county. It would be six years before all the schools could be inspected unless the pace was accelerated. At the same meeting the Education Committee submitted a recommendation, which, however, was not reached, that in cases where children sent to hospitals were discharged after the first attendance on the ground that no treatment was necessary, the examination at the hospital should be regarded as "school medical inspection" within the meaning of the Act.

DISCOVERY OF A VESTIGIAL ORGAN IN THE HUMAN BRAIN.

AT a meeting of the Royal Society on June 2nd Professor Dendy gave an account of the vestige of a remarkable organ he has discovered in the human brain. The discovery is the result of a prolonged investigation of those very large and peculiar fibres (Reissner's) known to exist in the spinal cord of fishes and amphibians, but of unknown meaning and function. These fibres have a peculiar relation to an ependymal organ in the roof of the aqueduct of Sylvius. This organ Professor Dendy proposes to name the "subcommissural organ." He has traced its existence in the mammalia. In the chimpanzee it forms an epithelial recess in the roof of the iter, just behind the posterior commissure: hence the proposed name, "subcommissural organ." In the human fœtus of the fifth month Professor Dendy found the organ was the same in form as in the chimpanzee, but in the adult brain the cavity or recess of the organ becomes shut off from the lumen of the iter. The significance of the subcommissural organ and of Reissner's fibres is unknown, but Professor Dendy is of opinion that the fibres are not nervous in nature, but probably serve a mechanical function. He is further of opinion that the atrophy of the organ in the higher primates is probably related to the assumption of the erect posture.

THE annual garden party and distribution of prizes at Guy's Hospital will take place this year on Thursday, July 7th. The prizes will be distributed to the successful

students by Professor Howard Marsh, professor of surgery in the University of Cambridge.

THE Local Government Board has informed the London County Council that it does not see its way at present to undertake an inquiry into the need for public slaughter-houses in London, as suggested by the Council in November, 1909.

REPORTS OF THE LANCET UPON Disinfectants.

THE following report has been sent to Messrs. Edward Cook and Co., Limited, Soapworks, Bow, London, E., upon a sample of Cofectant (surgical) disinfectant fluid which they requested us to submit to chemical and bacteriological examination by the methods described in our Commissioners' report which appeared in THE LANCET of Nov. 13th, 20th, and 27th, 1909, and in an annotation in THE LANCET of May 17th, 1910:—

"THE LANCET" TEST.

Report on Disinfectant marked Cofectant (Surgical) received from Messrs. Edward Cook and Co., Soapworks, Bow, London, E., May 27th, 1910. Stated price to the public, 1s. 1½d. *(bottle containing 6 fluid ounces). Ref. No. D004-25.*

(1) BACTERIOLOGICAL.

Disinfectant under Test.

THE ADVANCEMENT OF MEDICINE BY RESEARCH:

ADDRESSES BY THE EARL OF CROMER AND SIR DAVID BRUCE.

THE Research Defence Society held its annual general meeting on June 3rd in the library of the Royal College of Physicians of London, with Lord CROMER, the President of the society, in the chair.

There was a good gathering, though the honorary secretary, Mr. STEPHEN PAGET, read letters of regret from many unable to attend.

The Hon. SYDNEY HOLLAND, in presenting the report of the committee, said that the members and associates now numbered 3360, being an increase during the year of more than 800. Antivivisection shops had been opened and had proved a good advertisement for the society, which circulated its own literature, and thousands of leaflets had been distributed outside such shops.[1] The committee was informed that the final report of the Royal Commission on Experiments on Animals would be published shortly, and they would make arrangements for presenting the facts of the report to the public. The society wished the public to know what good had been done by experiments on animals and in what a merciful way vivisection was carried out in this country at the present time. He did not think there was any Englishman who could fail to be disgusted with a pamphlet given away on the day of the King's funeral stating that the King's death was due to the knowledge gained by experiments on animals. It was a despicable thing to use the sorrow and excitement of that moment to promulgate such an untruth.

Sir RICHARD DOUGLAS POWELL, in moving the adoption of the report, said it was deplorable that a society should have to protect the public from the machinations of the cliques now dominating and misguiding other associations, whose proper work should be to supplement the efforts of science to abolish pain and to prolong life. For one animal life sacrificed in an experiment hundreds were saved. He had had to sign over a thousand certificates permitting experiments and two-thirds were mere pin-pricks for inoculation, while anæsthesia was required in all the rest. If in his researches the late Dr. Koch took a small toll of animal life he paid back to them a thousand-fold in the animal life and suffering which his great work would save and alleviate in the future. They could not but observe in the readiness of many sentimentalists to be imposed upon and exploited a fresh illustration of the truth and force of Mr. Roosevelt's remark: "Of all broken reeds sentimentalism is the most broken reed on which righteousness can lean."

Sir DAVID BRUCE seconded the resolution in the following eloquent speech:—

My Lord, Ladies, and Gentlemen,—It seems a pity that it should be necessary year after year to affirm propositions which one would think were self-evident—to repeat, for example, that animal experimentation is absolutely necessary for advance in our knowledge of the prevention of disease; or that experimenters do not torture or inflict unnecessary pain on animals. For, on the contrary, in 999 cases out of 1000 so-called vivisections there is no pain inflicted, nothing more than the injection of a drop of fluid under the skin by means of a fine hypodermic needle. No less than 97 per cent. of all experiments on animals in this country are inoculations, or experiments of the nature of inoculations, involving no sort or kind of operation on any animal. No operation, more than the lancing of a vein under the skin, is allowed to be done on any animal, except under an anæsthetic. It is unfair of the opposite party to appeal by caricatures and sensational posters to the emotions of the public rather than to their reason. All this yearly repetition seems a work of supererogation, a thrice killing the slain; but as long as human nature is constituted as it is, I am afraid it will require to be done. The worst of it is, that we cannot console ourselves with the feeling that by bringing forward irrefragable proof of the beneficent results of the work we will convince our opponents and turn them from cursing to blessing us. That will not be so. There are people at the present time so constituted as to the nerve cells of their brains that they believe the earth

[1] We review certain of these leaflets in a leading article on p. 1628.

is flat; and many other equally erroneous notions are held just as firmly. It must be remembered that these people may be well endowed in other respects; and the only way to explain the phenomenon is by saying they are monomaniacs—that is, a particular part of their brain is abnormal, twisted, or imperfectly developed. Else how can it be that there are people who say that consumption is not caused by the bacillus tuberculosis; that Malta fever is not caused by the micrococcus melitensis; that sleeping sickness is not caused by a trypanosome. Will any one of our opponents, who are so loud in print, drink a little of the milk of a goat affected with Malta fever? or introduce under his skin a single sleeping sickness trypanosome? Or allow an infected tsetse fly to bite him? Not a bit.

That reminds me, that in 1903, when we called a meeting of the Uganda chiefs together to explain to them that sleeping sickness was caused by the entrance of a blood parasite into their bodies, that this was carried from the sick to the healthy by the "Kivu," or tsetse fly, and that the way to stop the sleeping sickness was to remove the natives from the fly area, they politely disbelieved us, saying that the fly had always been on the lake-shore in their time and in their fathers' time, and that, therefore, it was harmless. I then said to Sir Apolo Kagwa, the Prime Minister, that if he did not believe the fly carried sleeping sickness he should go and sit among them under the shade of the trees on the lake-shore in order to show everyone the faith he had in the innocence of the fly. But he answered, God forbid. But these same so-called uncivilised natives, whose untutored minds could not perhaps at once grasp the position, a few years later were so convinced of the truth of what we told them that they cleared the lake-shore and islands of their inhabitants, with the result that, so far as I am aware, at present not a single new case of sleeping sickness is being contracted in Uganda proper, and the toll of human lives to this plague has ceased to be paid. This toll has been estimated at 200,000 out of a population of 300,000. In one island alone—Buvuma—with a population of 22,000, 18,000 are reported to have perished. What a saving of human life has been achieved by the simple means of removing the population from the fly area, and the necessary knowledge was acquired mainly by animal experimentation.

During the last 18 months the study of sleeping sickness in Uganda has been continued, and before I left at the end of last year we had carried out more than 2000 experiments. It was very important to find out how long the fly remained infective, as on this would depend the repopulation of the lake-shore and islands. By animal experimentation it was found out that the flies when once they had sucked blood from an infected animal might remain infective for at least 75 days; and, again, that the flies on the lake-shore were still infective, although the natives had been removed some two years before. By animal experimentation we also discovered that cattle and antelope could be infected by sleeping sickness, and, in fact, we found a cow on the island of Kome which had been naturally infected. We made many experiments to find out if the birds and large mammals, such as the hippopotami, on the lake-shore were capable of giving sleeping sickness to man by means of the fly; but although we injected the blood of many water-birds, antelope, and hippopotami into healthy susceptible animals, we discovered no infected animals, save the cow mentioned. The importance of these experiments is great, as the repopulation of some thousands of square miles of the very fertile land lying along the lake-shore depends on the results gained.

By animal experimentation we found out the cause and nature of a disease called "Amakebe," which kills 70 to 80 per cent. of the calves born in Uganda. This had eluded all other workers up to the present. The finding out of the true cause and mode of spread of a disease is a big step in its prevention. By animal experimentation we found out the nature of several of the most important diseases of the domestic animals in Uganda, and on more than one occasion nipped an epidemic in the bud, thus earning, if they had known it, the gratitude of the animals themselves. By animal experimentation we found out the nature of a disease among natives in Uganda called "Muhinyo." As this is interesting I will describe it in detail. When the Sleeping Sickness Commission passed through Kampala, the native capital of Uganda, at the end of October, 1908, on the way to their camp at Mpumu, they were informed by Apolo Kagwa that a new disease had broken out in the Province of Ankole, and that many people were sick. This was the disease which had been investigated in 1906 and described as beri-beri. At that time it was reported that in one part as many as 25 per cent. of the natives were down with it. In the same year another observer described it as dengue, with persistent joint pains. Again, in 1909 a third doctor investigated the disease, and came to the conclusion that it was kala-azar. Now, none of these observers used animal experimentation. They used the methods of clinical diagnosis, each differently and all wrong. If anyone of them had injected a few drops of the blood of one of these cases into a monkey the nature of the disease would have been manifest. Thanks to the kindness of Apolo Kagwa, the Commission had the opportunity of seeing a case of muhinyo, which was sent to the laboratory at Mpumu from Ankole, a distance of some 200 miles. This man was carefully examined, but as it was an old case nothing very definite was discovered. It was decided to go to the district and see cases on the spot. In this way some 50 cases were examined. The chief symptoms were fever, profuse sweating, pains and swellings of the joints, and extreme weakness and emaciation. The natives looked like scarecrows. The disease was of long duration, many of them having been ill for several months. Cultivations were made from the blood and spleen of some of the cases, which showed that there was a small micrococcus present very similar to micrococcus melitensis. Monkeys and rabbits were inoculated with this muhinyo organism, and at the same time animals were inoculated with a strain of micrococcus melitensis brought from Malta. Now, when the organism separated from the muhinyo cases was tested with the serum of the animal into which the micrococcus melitensis had been injected, it gave rise to marked clumping of the micrococci, and when the micrococcus melitensis brought from Malta was tested with serum from the muhinyo cases the same phenomenon occurred. It was therefore decided that, as the symptoms of the disease were the same, the organism isolated the same, the character of the growth of the organism the same, that both agglutinated with the same serum, the disease muhinyo was in reality Malta fever; and the curious fact was established that here, on the shores of Lake Albert Edward, in the centre of Africa, thousands of natives were sick of Malta fever, and more than a thousand had been reported as having died from it.

Now, as it had been proved beyond the shadow of a doubt that Malta fever is caused in Malta by the drinking of goats' milk, and by that alone, it was a matter of importance, as well as curiosity, to find out if the goats in the affected district also suffered from Malta fever. Last June Apolo Kagwa was asked if it would be possible to have a number of goats sent to the laboratory from a place in Ankole where this muhinyo was common. The Prime Minister said he would try to have them sent. In July 24 goats arrived, and were at once examined. Among them the blood of three was found to give the agglutination reaction with the micrococcus melitensis got from a case of muhinyo, and also with the germ of Malta fever brought from London. One of these animals was then killed and cultures made from its spleen. These cultures grew a micrococcus which had all the cultural and morphological characters of the micrococcus melitensis. Finally, the micrococci were tested as to their power of agglutination with a known Malta fever serum and were found to react in high dilution. This, then, completed the proof that muhinyo was Malta fever, and that in Central Africa, as in Malta, the infection was caused by the drinking of goats' milk.

In conclusion, I would like to say a few words about Malta fever in Malta. I hear it is said in the newspapers that goats' milk in Malta is quite harmless, and that the doctors had got rid of Malta fever by simply calling it simple continued fever. This simple continued fever is quite a distinct disease and had been made the subject of study in Malta during the last year and the present one. In 1908 Dr. Doerr, an Austrian army surgeon, discovered that it is a fever caused by the bites of the common sand-fly, which is common in Malta during the summer months, and the parasite which is conveyed from man to man is, like that of yellow fever, so small as to be invisible under the highest powers of the microscope. As none of the lower animals are susceptible to this disease all the animal experimentation has been carried out on man himself. Our soldiers have been

found plucky enough to come forward and offer themselves. As Colonel C. Birt, R.A.M.C., who conducted this investigation, writes: "Science and humanity owe a debt of gratitude to the self-sacrificing courage and zeal of the gunners of the 99th Company of the Royal Garrison Artillery. When the object of the research was explained to them they vied with one another in offering themselves as cheerful victims for the sake of mankind. The men of this company are of splendid physique and they rejoice in rude health, which they maintain by the enthusiastic pursuit of athletics. Those volunteers who were selected for experiment had resided less than a year in the island. They were all exceptionally healthy, strong, and muscular men. The aches and pains during the acme of phlebotomous fever make the sufferer an object of our profound pity. Those who, of their own accord, knowingly submit to them are martyrs indeed." In this way it was proved that sand-flies fed on a soldier suffering from simple continued fever and then conveyed by the quickest route to England were capable of setting up the disease in two Royal Army Medical Corps officers in London. Also that blood taken from a patient and filtered through a porcelain filter could give rise to the disease in healthy men. This shows that the disease is caused by an ultra-microscopical parasite, and that this parasite is conveyed from the sick to the healthy by the sand-fly. This year the study of the habits of the sand-fly is being pursued with energy, and I hope that within a short time simple continued fever will have disappeared as completely from Malta as Malta fever has done. I may here give the latest figures for Malta fever:—In 1905, in the Army alone, there were 643 cases, and in the Navy about the same number; in 1906, 147; in 1907, 11; in 1908, 5; in 1909, 1; in 1910, 0.

Lastly, I hear that it is reported in the daily press that the goats which were taken to America and were supposed to have set up an epidemic on board the s.s. *Joshua Nicholson*, were really quite healthy and never gave rise to any disease. I have just had a report sent to me by the Board of Agriculture in America, from which it appears that as soon as these goats were landed they were placed in quarantine and subjected to a most rigorous investigation. The man who took them from Malta did not believe in the milk theory, and he died. A delicate woman who lived on the station was fed on the goats' milk, as it was considered to be very nourishing; she took a severe attack of Malta fever and also died. The goats, 60 in number, were kept under observation for some two years, those which showed severe infection with Malta fever being slaughtered from time to time. The result was that they have been all slaughtered, as they all developed sooner or later this serious human disease. Not one could be saved, although the greatest efforts were made to do so.

Mr. ANTHONY HOPE HAWKINS proposed, and Mrs. SCHARLIEB seconded, a vote of thanks to Lord Cromer and to the President of the Royal College of Physicians of London for the use of the library. Mr. Hawkins said he believed the speakers that afternoon were carrying on what was probably the most beneficent work of the present age.

The EARL of CROMER, in returning thanks, said that if the British public were becoming gradually acquainted with their work and motives it was mainly due to the unselfish and untiring zeal of Mr. Stephen Paget. When he (Lord Cromer) was asked to speak on the subject of vivisection, as had frequently been the case during the last few years, he was reminded of a statement made by Mr. Cobden during the Anti-Corn Law agitation. Mr. Cobden said there was only one way of getting an idea into the heads of the British public, and that was to go on repeating the same thing over and over again in different language. That was generally what he had to do. He was one of those who belonged to the army and who knew nothing about organisms. He knew something about organisation, but that was quite another matter. What they had to do was to convince the public that those who advocated the progress of science and who endeavoured to prolong human life and mitigate human suffering were the true friends of humanity, and that their opponents who, from perhaps good but mistaken notions, placed obstacles in their path were not the true humanitarians. They had to judge of the truth by results, and they had been told of remarkable results in the case of sleeping sickness and other African diseases by the highest living authority on the subject. A pamphlet had been circulated by their society entitled "Recent Surgical Progress," by Professor W. W. Keen, an eminent American surgeon, which contained facts of the same nature. The author asked what the friends of experimental research had done, and he (Lord Cromer) said they had discovered antiseptic surgery and made possible all abdominal surgery. They had also made possible all modern surgery of the brain, and had gone far to prevent lockjaw. They had enormously reduced the death-rate in cases of compound fractures and in the operation of ovariotomy. In some parts of the world, notably in Havana, they had practically abolished yellow fever. They had made possible the cure of nearly all cases of hydrophobia, had immensely reduced the mortality in cases of diphtheria, and also in that terrible disease cerebro-spinal meningitis. They had shown the cause and method of propagation and prevention of the deadly malaria which devastated whole regions and armies. They had reduced the mortality from tuberculosis by from 30 to 50 per cent., due to the discovery made by the great German scientist, whose death not only his native country but the whole civilised world had recently had cause to mourn. Nor were human beings alone benefited. The brute creation had reaped enormous benefit from their humane researches, for the causes of tuberculosis, Texas fever, anthrax, glanders, and other infectious diseases of animals had been discovered. He had not nearly exhausted the list, but was not that a noble record? Professor Keen, in his pamphlet, said the foes of experimental research had done nothing but stand in the way of progress. Not a single human life had been saved by their efforts; not a single household made happy; not a single disease had had its ravages abated or abolished. He himself was quite prepared to leave the society's case there, asking any impartial person, whether professional or unprofessional, to compare their noble record with the sterility of their opponents. A Bill had been recently introduced into the House of Commons by Sir Frederick Banbury and Sir Francis Channing having for its object the total prohibition of experiments on living dogs. Of all animals, dogs were the most faithful companions of man. The love of dogs was not confined to antivivisectionists, but putting sentiment aside he asked whether such a proposal could be justified. He thought no such justification could be found. If dogs were to be exempted, why not cats, horses, guinea-pigs, and other animals? They had it on the highest professional authority that the use of the dog was indispensable for the furtherance of their knowledge in respect of certain functions of the human body. Further, a very large number, he believed some 20,000, of stray dogs were annually put to death in London through the instrumentality of the lethal chamber in the Battersea Dogs' Home. He was unable to give the exact number of dogs used annually for experimental purposes in this country, as the official returns did not specifically distinguish between dogs and other animals. But it might confidently be asserted that the number had to be reckoned, not by thousands, but by hundreds, and that by far the greater portion were put to death in a manner as painless as that adopted at the Battersea Dogs' Home. The only result, in fact, of the passing of the Bill would be that a few hundred dogs a year more would pass into the Battersea lethal chamber. He thought it was the duty of everyone connected with the society to offer what legitimate opposition they could to such a measure, and if it ever reached that menaced branch of the Legislature to which he belonged he would certainly do his utmost to oppose it. There was another Bill which had been prepared by Mr. Stephen Coleridge, and he (Lord Cromer) could not do better than illustrate his views upon it by a historical anecdote. It was related that in 1802, when the country was threatened by invasion from France, a large number of Volunteer corps were formed. Amongst others, the Articles of Association of one corps in the neighbourhood of the Cinque Ports, of which Mr. Pitt was then the Warden, were submitted to that statesman. It was a very elaborate and detailed document containing a great number of carefully worded provisions as to how, when, and where the Volunteers were to be employed. The words "except in case of actual invasion" frequently occurred. Towards the close of the document Mr. Pitt came across a provision which was to the effect that under no circumstances whatsoever was this corps of Volunteers ever to be sent out of the United Kingdom. Mr. Pitt lost patience, and added to the clause "except in the case of actual invasion." That was very much the treatment which animal experimentation received from Mr. Stephen Coleridge. His

Bill professed to allow vivisection, but surrounded it with such an enormous number of restrictions as to render the working of the Act practically impossible and altogether ineffective for scientific research. For instance, in one clause it was provided that no one was to be allowed to conduct any experiment unless he could produce a certificate signed by at least one justice of the peace and one clergyman, stating that he enjoyed a high reputation for humanity. He thought that such a proposal was almost unique in their legislative annals. What standard of humanity was to be adopted? A justice of the peace who was a member of the Antivivisection Society would adopt one standard and a justice of the peace who was a Master of Hounds would adopt a very different one. The proposal was really absurd and was almost sufficient for the Bill to be laughed out of court. Could it be reasonably suggested that an eminent man like Professor Starling was to be compelled to go and look about for a justice of the peace and a clergyman who would give him a certificate for humanity? If this clause were to become law he would like to propose a very useful amendment that no one be allowed to open his lips on the subject of vivisection unless he could produce a certificate signed by at least two judges and a brace of bishops that he enjoyed a high reputation for commonsense and accuracy. In conclusion, Lord Cromer said he was told that the report of the Commission would probably be issued in July, but the long delays which had already occurred precluded him from entertaining any very sanguine hope that this expectation would be realised. When the report was issued it would be a very valuable document and would receive the greatest attention from the general public, and from none more than from every member of the Research Defence Society.

THE OFFICIAL RECOGNITION OF SYNTHETIC PRODUCTS AS EXPRESSED BY THEIR INCLUSION IN DIFFERENT PHARMACOPŒIAS.

THE establishment of pharmacology on a scientific basis and the consequent development of rational therapeutics dates from the second decade of the past century, and coincides with the isolation of the active principles of many drugs of plant origin. At the same time, the progress in chemistry has enabled the production of pure chemicals. In the place of preparations of more or less unknown composition or purity the modern physician has at his disposal an armamentarium of products answering to definite standards, and this not alone as regards their chemical properties, but, a matter of greater importance, as far as their action on the human organism in certain conditions is in question.

Very soon, however, it became apparent that the action of several of even the purest and most useful remedies might be paralysed by certain undesirable by-effects, or by an unexpected reaction on the part of the individual. To recapitulate the efforts made to eliminate these drawbacks would be to trace the development of pharmacy and of pharmaceutical chemistry during the past years. To put it briefly, three procedures have been adopted in this direction: (1) the production of a combination of the preparation in some form in which it no longer displays its unwelcome by-effects; (2) the alteration of the chemical structure of the substance; and (3) the production of new bodies. As representatives of the first method, figure the well-known combinations of bromine and iodine with an oily medium, while the derivatives of morphine (benzoyl, ethyl, and diacetyl morphine) will serve as illustrations of the second. The third method, the production of synthetic preparations, has led to the manufacture of a very considerable number of products, in a great measure due to the enterprise of German research chemists acting in coöperation with pharmacologists.

In spite of their thoroughly scientific foundation and of the extensive trials to which the majority have been submitted, only a restricted number can claim to have gained a permanent place in materia medica, while others, although presenting numerous advantages in certain cases, have failed to realise the expectations with which their advent was heralded.

In view of the approaching issue of a new edition of the British Pharmacopœia, it is a matter of interest to ascertain to what extent this class of preparation has gained official recognition in other countries, as reflected by their inclusion in the various national Pharmacopœias. Before entering into the subject, one point must be made clear. It must not be overlooked that the process of manufacture of a large number of these synthetic products is covered by patents in many countries, or the name under which they have been introduced is registered as a trade-mark. Without entering into the controversial subject of substitution, it may be mentioned that where either or both of these conditions prevail there is some reluctance on the part of the compilers of a Pharmacopœia to give official recognition to what constitutes a monopoly. On the other hand, the adoption of the scientific name as a title for many of these products is handicapped by the unwieldy length of the appellation, and for this reason is foredoomed to be little used, yet, if injudiciously abbreviated, errors may be the result. The coining of a new name as the official title may again only create more confusion; this has to a certain extent been adopted in the United States Pharmacopœia in 1905, where we find the title "Hexamethylenamina" in lieu of the full "Hexamethylenetetramina."

The attitude of the various Pharmacopœias on this subject is rather interesting. In no case do we find that the full scientific names alone have been adopted as titles, but where possible a shorter designation has been chosen. The recognition of the names under which these preparations have been introduced, the "popular names," as the Japanese Pharmacopœia terms them, differs very considerably in the different countries.

The following Pharmacopœias have almost exclusively adopted the chemical names as titles[1]: Belgium (1906), Denmark (1907), and Holland (1905), where in some cases the popular name is given as a synonym under the official title; in France (1908) and Austria (1906) the popular names, where mentioned, appear as a footnote to the respective monographs; in Japan (1907) these appellations are given in two separate tables in the appendix; in Germany (1900) they appear in the table of synonyms, as is also the case in Switzerland (1907); in the latter country they are also mentioned in the table of maximum doses. In Italy (1909), Russia (1902), Spain (1905), and Croatia-Slavonia (1901) the popular names figure largely as the official titles or as synonyms under the latter, only in the case of the Italian Pharmacopœia it is distinctly stated that the use of these names does not constitute any official recognition of the proprietary rights held by certain persons, but that this course has been dictated for reasons of convenience. In Sweden (1908) and in Hungary (1909) in each case the popular names only appear in three instances. In the United States Pharmacopœia (1905), if we except antipyrin and iodol, these are completely ignored.

On examining the above 15 Pharmacopœias for the inclusion of recent synthetic preparations, we find that four are official in all: antipyrin, phenacetin, salol, and sulphonal, the only four also included in the British Pharmacopœia. In these 15 Pharmacopœias, which have all appeared during the present century, we find the following synthetic preparations to occur most frequently, as indicated by the figures against the name of each preparation. The preparations which will figure in the new German Pharmacopœia to be issued shortly have here been taken into consideration, and as it may be assumed that the products are best known by their popular names, these have been adopted regardless of the differences in the official nomenclatures:—

Airol	2	Lactophenin	3
Aristol	5	Novocaine	2
Aspirin	8	Protargol	6
Benzonaphthol	4	Pyramidon	3
Betol	2	Salipyrin	11
Creosotal	4	Salophen	4
Dermatol	14	Stovaine	2
Dionin	4	Tannalbin	6
Diuretin	13	Tannigen	4
Duotal	14	Tannoform	3
β Eucaine	4	Trional	12
Euquinine	3	Urotropin	7
Heroin	6	Veronal	4
Iodol	4	Xeroform	3

[1] The dates in brackets denote the year of issue of the Pharmacopœia.

An interesting comparison is afforded by the maximum doses fixed for some of the above preparations. In the following table the first figure under each country indicates the maximum single dose (in grains), the second the maximum dose within 24 hours:—

—	Italy.		France.		Hungary.		Switzerland.	
Aspirin	15	75	15	90	—	—	—	—
Diuretin ...	15	90	—	—	15	120	15	90
Dionin	—	—	—	—	¾	2½	¾	2½
Duotal	15	45	7½	30	15	75	15	45
Heroin	⅛	⅞	—	—	—	—	1/12	¼
Trional	30	60	30	30	—	30	30	60
Veronal... ...	15	30	—	—	—	—	15	30
